Administration. Victoria enjoys almost absolute autonomy. The practical government of the country rests with the parliament consisting of two houses. The legislative council contains 42 members elected by 14 electoral provinces. Each member holds his seat for six years, a third of them retiring every two years but being eligible for re-election. To be eligible for election a candidate must be over thirty years of age and possessed of freehold property to the extent of £100 [$486.00] per annum. The electoral body consists of all citizens over twenty-one years of age, either possessing property of the yearly value of £10 [$48.60] or paying rates on property of not less than £25 [$121.50] annual value. To these are added all graduates of universities and all members of the learned professions. Members of the legislative council receive no payment. They form a sort of court of revision of the work done in the lower house. The legislative assembly consists of 86 members elected by 55 electoral districts; they are paid at the rate of £300 [$1458.00] a year. A general election must take place every three years. In all other respects it resembles very closely the British House of Commons. Every man of the full age of twenty-one years who has taken out his elector's right has a vote for the election of a member for the district in which he resides. All voting is by ballot. The governor is appointed by the sovereign of the British empire. He has the power of assenting to or rejecting bills sent up to him from parliament, except eight classes, which he is bound to refer to the sovereign, who can disallow all bills by signifying disapproval of them within two years of their being passed by the legislature. The governor is assisted by an executive council consisting of the ministers and ex-ministers of the crown. The cabinet consists of treasurer, chief secretary, minister of public instruction, commissioner of trade and customs, minister of mines, postmaster-general, minister of lands, minister of public works, minister of agriculture, solicitor-general, attorney-general, and minister of defence. The civil service of Victoria is under the control of three commissioners, who are appointed for a term of three years by Government, but are then wholly independent. Their business is to make all appointments, determine all promotions, and watch over the administration of the Civil Service Act. Their existence has effectually abolished the evils of political patronage.

Finance. During the financial year 1885–86 the total receipts of the colony from all sources amounted to £6,945,099 [$33,753,181.14], and the expenditure to £6,513,539 [$31,655,799.54]. On 30th June, 1887, the public debt amounted to £33,119,164 [$160,959,137.04], more than twenty-three millions [$113,780,000] of which have been borrowed for the construction of railways.

Education. Victoria possesses a most efficiently organized system of state schools, where the education given is free, secular, and compulsory. The schools number 1826, with 4050 teachers, and 189,637 scholars. The average attendance is 119,488. The state awards each year for competition among boys and girls of the state schools eleven exhibitions of the yearly value of £35 [$170.10] each, tenable for six years, and two hundred of the value of £10 [$48.60] each for three years. The successful candidates of the former must go for two years to a college or grammar school and then enter the university of Melbourne; those of the latter class attend the nearest grammar school. The Roman Catholic Church supports 130 primary schools with 18,000 scholars. Secondary education is quite unconnected with the state and wholly unsupported by it; but the churches and private enterprise provide all that is needed. The Church of England has large grammar schools in Melbourne and Geelong. The Presbyterians have colleges in Melbourne, Geelong, and Ballarat, and a ladies' college in Melbourne. The Wesleyans have colleges for males and females respectively in Melbourne. The Catholics have also two institutions. Private grammar schools exist in all important towns. The university has four faculties—arts, law, engineering, and medicine—in which in 1886 the students numbered respectively 166, 61, 9, and 212. There are 14 professors and 10 lecturers. About one thousand candidates present themselves every year for matriculation, but only about 160 actually enter the university each year. A considerable number of ladies have matriculated and are pursuing their studies in the university. In 1886 the number of persons who gradauted was 124 and the total from the beginning of the university (founded in 1853) has been 1169. The compulsory clause has not been in force more than ten years, and it has not yet produced its full result in raising the general standard of education. At present 94 per cent. of the children between the ages of six and fifteen attend school, but nearly a fourth of these fail to make up 40 days in the quarter. Still of persons above fifteen years of age 96 per cent. can read and 92 per cent. can both read and write. These results would be even more favorable but for the presence of 13,000 Chinese in the colony nearly all of whom are returned as illiterate, neither reading nor writing English.

Population. The population in 1886 was 1,003,043 (531,452 males and 471,591 females), of whom about one-half were born in the colony and rather less than a third in the British Isles. The estimated population at the end of 1887 was 1,035,900. In religion a third are Episcopalians, a fourth Catholics, a sixth Presbyterians, and an eighth Wesleyans.

There are now only about 780 of the aborigines left; but they never were numerous. When white men first settled in the colony, there probably were not 15,000; some estimates place them as low as 5000. Those who now remain live on stations maintained by the Government. They are allowed great freedom, with plenty of land to roam over, but each station is under the paternal care of a superintendent. Nevertheless they are steadily diminishing in numbers.

History. The eastern shore of Victoria was first explored by Surgeon Bass, who in January, 1798, rounded Cape Howe from Sydney in a whale-boat. The western half was first examined in 1800–1 by Lieutenant Grant, when he discovered Port Phillip. In 1802 Flinders in charge of a British exploring expedition and Baudin at the head of one sent out by Napoleon did exploring work in the same waters.

The colony was at first known as Port Phillip, settlement being confined to the shores of that inlet. The earliest attempt to colonize this part of Australia was made in 1803, when Collins was sent out with a number of convicts and landed on the sandy peninsula to the east of the entrance to the bay. But, water being scarce, he went across to Tasmania. In 1835 John Bateman and John Pasco Fawkner brought over from Tasmania rival pastoral companies. Previous to this the brothers Henty had formed a whaling station at Portland, and had resided there for two years. But, as this was a purely private enterprise, and not publicly known, the founding of the colony is rightly ascribed to Bateman and Fawkner. Before a year had passed about 200 persons had followed in their wake. At the end of 1839 there were 3000 persons on the banks of the Yarra; in 1841 these had increased to 11,000. In 1842 the small community began to agitate for separation from New South Wales, and in 1851, when its desires were realized, it numbered 97,000 persons. In this same year (1851) some of the Australian colonies received constitutions which rendered them self-governing, and among these the new colony of Victoria attained to the dignity of representative institutions. It was also in this year that the discovery of gold totally altered the character and prospects of Victoria. The discovery was first made in New South Wales in February, 1851, by Edward Hargraves; but a month or two elapsed before it became generally known. So great was the exodus to New South Wales that a committee of leading Melbourne citizens offered a reward for the first discovery of gold in Victoria. Numerous parties scoured the colony, with the result of finding gold at Clunes. Six weeks later the wonderful field of Ballarat was discovered, and attention was drawn to Victoria as a gold-producing country. In 1852 there were 70,000 arrivals in the colony, nearly all men. In 1853 there were 54,000, in 1854 there were 90,000, and so on, the population in 1861 being six times that of 1851. In 1854 the severity with which the license-fee of thirty shillings [$7.29] a month was exacted from miners, whether successful or not, led to a serious riot. A number of the ringleaders were brought to trial, but the juries acquitted them. In 1860 the ill-fated expedition of Burke and Wills left Melbourne on its bold dash across the continent. In 1863 the colony was thrown into much excitement over a constitutional struggle generally known as the "deadlock." The democratic party wished to introduce the fiscal system of protection to native industry, but, after the bill had passed the lower house, the upper rejected it. It was then tacked to an Appropriation Bill, which the upper house resolutely refused to pass. For a year all supplies were stopped, and the business of the colony was carried on without funds. In 1866 a compromise was effected; but then the struggle commenced anew. The English Government recalled the governor, Sir Charles Darling, for siding with the democracy; the lower house, thinking him ill-used, placed on the estimates a grant of £20,000 [$97,200] for Lady Darling, which the upper house threw out.[1] In 1868 Sir Charles received a lucrative position elsewhere, with £5000 [$24,300] from the colony as arrears of salary. The later history of the colony tells only of quiet, orderly, and unbroken prosperity. (A. SU.)

VICTORIA, capital of British Columbia and the principal town of Vancouver Island, in the southeast corner of which it is finely situated (48° 25′ 20″ N. lat., 123° 22′ 24″ W. long.), on a small arm of the sea, its harbor, however, only admitting vessels drawing 18 feet. The city has some fine streets, handsome villas and public buildings, Government offices, and churches. There are several schools, public and private, a free library, a theatre, a mechanics' institute, and a public park. The water supply is good. The town, which is connected by cable with the mainland, is a favorite holiday resort for the Columbians. Till 1858 Victoria was a post of the Hudson Bay Company. The city was incorporated in 1862; and according to the census of 1886, the population was 14,000, including Chinese and Indians, spread over an area of 4 square miles.

VICTORIA, a city of Brazil, capital of the province of Espirito Santo, 270 miles northeast from Rio de Janeiro, in 20° 18′ S. lat. and 40° 20′ W. long. Victoria, which has a white, Negro, and colored population (1880) of 12,500, stands on the west side of an island at the head of the Bay of Espirito Santo, the entrance of which is defended by five forts, and also rendered difficult of access by several other islets and reefs rising little above high-water mark. The town is regularly laid out and well-built, with some good streets, two or three fine churches, a substantial governor's residence, and a few other conspicuous buildings. The surrounding district grows much rice, sugar, and manioc, which with other produce are here shipped, chiefly for the neighboring coast towns.

Victoria, originally Espirito Santo, is one of the oldest Portuguese settlements on the Brazilian coast, having been founded in 1535 by Vasco Fernando Coutinho at a little distance from its present site, on the south side and nearer to the entrance of the bay. It took the name of Victoria in 1558 to commemorate the crushing defeat inflicted by Fernando de Sa on the allied Indian tribes of the Aimores, Tapininguins, and Goitacazes in that year. The original site is still occupied by a group of houses and buildings commonly known as the Villa Velha or "Old Town," which is separated from Victoria by the Rio Santa Maria flowing to the southwest corner of the bay.

VIDA, Marco Girolamo (*c.* 1489–1566), one of the most eminent Latin poets and scholars of the age of Leo X., was born at Cremona shortly before the year 1490. He received the name of Marcantonio in baptism, but changed this to Marco Girolamo when he entered the order of the Canonici Regolari Lateranensi. During his early manhood he acquired considerable fame by the composition of two didactic poems in the Latin tongue, on the *Game of Chess* and on the *Silkworm.* This reputation induced him to seek the papal court in Rome, which was rapidly becoming the headquarters of polite learning, the place where students might expect advancement through their literary talents. Vida reached Rome in the last years of the pontificate of Julius II. Leo X., on succeeding to the papal chair (1513), treated him with marked favor, bestowed on him the priory of St. Sylvester at Frascati, and bade him compose a heroic Latin poem on the life of Christ. Such was the origin of the *Christiad*, Vida's most celebrated, if not his best, performance. It did not, however, see the light in Leo's lifetime. Between the years 1520 and 1527 Vida produced the second of his masterpieces in Latin hexameters, a didactic poem on the *Art of Poetry.* Clement VII. raised him to the rank of apostolic protonotary, and in 1532 conferred on him the bishopric of Alba. It is probable that he took up his residence in this town soon after the death of Clement; and here he spent the greater portion of his remaining years. Vida attended the council of Trent, where he enjoyed the society of Cardinals Cervini, Pole and Del Monte, together with his friend the poet Flaminio. A record of their conversations may be studied in Vida's Latin dialogue *De Republica.* Among his other writings should be mentioned three eloquent orations in defence of Cremona against Pavia, composed upon the occasion of some dispute as to precedency between those two cities. Vida died at Alba on 27th September, 1566.

Vida's fame rests almost wholly on his Latin poems. These are more remarkable for their purity and grace of style than for qualities of imagination or powerful thinking. His contemporaries were of opinion that Vida approached more nearly to the ancients in majesty and gravity of diction than his rivals. Indeed, the *Poetica* can still be read with both pleasure and instruction. Though we miss the poetic glow of Poliziano's and Pontano's Latin compositions, and the exquisite workmanship of Flaminio's lyrics, there is in Vida so facile a command of the Latin language and metre that we might fancy ourselves listening to a writer of the Augustan age. The following lines will give a fair notion of his powers:

> Dii Romæ indigetes, Trojæ tuque auctor, Apollo,
> Unde genus nostrum cœli se tollit ad astra,
> Hanc saltem auferri tandem prohibete Latinis
> Artibus emineat semper studiisque Minervæ
> Italia, et gentes doceat pulcherrima Roma;
> Quandoquidem armorum penitus fortuna recessit,
> Tanta Italos inter crevit discordia reges;
> Ipsi nos inter sævos destringimus enses,
> Nec patriam pudet externis aperire tyrannis.

---

[1] [H. Manners Chichester says the Legislature after rejecting these grants to him and his wife, in 1870, on hearing of his death voted £20,000 to his widow.—AM. ED]

This pious prayer was not granted in the age which followed the council of Trent.

Vida's poems were collected and printed at Oxford in 1722, and an enlarged edition appeared in 1731. For an account of his works, see Symond's *Renaissance in Italy*, vol. ii.

VIEN, JOSEPH MARIE (1716–1809), French painter, was not only the master but the forerunner of David, and the author of the classic movement which, inaugurated under Louis XVI., ran itself out under the first empire. He was born at Montpellier, 18th June, 1716. Protected by Comte de Caylus, he entered at an early age the studio of Natoire, and obtained the great prize in 1745. He used his time at Rome in applying to the study of nature and the development of his own powers all that he gleaned from the masterpieces around him; but his tendencies were so foreign to the reigning taste that on his return to Paris he owed his admission to the academy for his picture Dædalus and Icarus (Louvre) solely to the indignant protests of Boucher. When in 1776, at the height of his established reputation, he became director of the school of France at Rome, he took David with him amongst his pupils. After his return five years later, his fortunes were wrecked by the Revolution; but he undauntedly set to work, and at the age of eighty (1796) carried off the prize in an open Government competition. Bonaparte acknowledged his merit by making him a senator. He died at Paris on 27th March, 1809, leaving behind him several brilliant pupils, amongst whom were Vincent, Regnault, Suvée, Ménageot, Taillasson, and others of high merit; nor should the name of his wife, Marie Thérèse Reboul (1728–1805), herself a member of the academy, be omitted from this list. Their son, Marie Joseph, born in 1761, also distinguished himself as a painter.

VIENNA, (Germ. *Wien*), the capital and largest city of the Austrian-Hungarian empire, is situated on the right bank of the Danube, in 48° 13′ N. lat. and 16° 23′ E. long., at a height of about 550 feet above the level of the sea. It lies at the base of the last outlying spurs of the eastern Alps (the Wiener Wald), at the beginning of a plain which stretches eastwards to the Carpathians. The main channel of the Danube passes to the north of Vienna; but an arm of the river, the Danube Canal, passes through the city, dividing it into two unequal parts. Into this arm, on the east side of Vienna, flows the dirty and generally insignificant stream called the Wien, which gives its name to the city.[1] Vienna is the principal residence of the emperor, the see of an archbishop, the seat of the imperial and Cisleithan (Austrian) ministries, the meeting-place of the Austrian diet, and also the meeting-place, alternately with Buda-Pest, of the delegations (compare AUSTRIA). Vienna is now officially divided into the following ten municipal districts,—the inner town (Innere Stadt) or old city of Vienna, Leopoldstadt, Landstrasse, Wieden, Margarethen, Mariahilf, Neubau, Josefstadt, Alsergrund, and Favoriten. The inner town, which lies almost exactly in the centre of the others, is, unlike the older parts of most European towns, still the most aristocratic quarter, containing the palaces of the emperor and of many of the nobility, the Government offices, many of the embassies and legations, the opera house, and the principal hotels. Leopoldstadt, which is the only district on the left bank of the Danube Canal, is the chief commercial quarter, and is inhabited to a great extent by Jews. Mariahilf, Neubau, and Margarethen are the chief seats of manufacturing industry. Landstrasse may be described as the district of officialism; there too are the British and German embassies. Alsergrund, with the enormous general hospital, the military hospital, and the municipal asylum for the insane, is the medical quarter. The inner city or Vienna proper, was formerly separated from the other districts by a circle of fortifications, consisting of a rampart, fosse, and glacis. These, however, were removed in 1858–1860, and the place of the glacis has been taken by a handsome boulevard (Ring-Strasse), 2 miles in length and about 150 feet in average width. A series of external works, consisting of a rampart and fosse, were constructed in 1704 to surround the whole city at that time, including its suburbs; and these are still maintained as the boundary-line for the city imposts, and separate the above-named districts from the as yet unincorporated suburbs. This second girdle of fortifications is known as the Lines (Linien), and a second wide boulevard (Gürtel-Strasse) follows their course round the city.

Near the centre of the inner city, most of the streets in which are narrow and irregular, is the cathedral of St. Stephen, the most important mediæval building in Vienna, dating in its present form mainly from the 14th and 15th centuries, but incorporating a few fragments of the original 12th-century edifice. Among its most striking features are the fine and lofty tower (450 feet), rebuilt in 1860–64; the extensive catacombs,[2] in which the emperors were formerly interred; the sarcophagus (1513) of Frederick III.; the tomb of Prince Eugene of Savoy; thirty-eight marble altars; and the fine groined ceiling. A little to the southwest of the cathedral is the Hofburg, or imperial palace, a huge complex of buildings of various epochs and in various styles, enclosing several courtyards. The oldest part of the present edifice dates from the 13th century, and extensive additions are now being made according to the plans of the architect Fischer von Erlach (1650–1723). In addition to private rooms and state apartments, the Hofburg contains a library of 400,000 volumes and 20,000 MSS.; the imperial treasury, a storehouse of objects of the greatest historical interest and intrinsic value; a cabinet of coins and antiquities; and other important collections. In the old town are the two largest of the Höfe, extensive blocks of buildings belonging to the great abbeys of Austria, which are common throughout Vienna. These are the Schottenhof (once belonging to the "Scoti," or Irish Benedictines) and the Mölkerhof, adjoining the open space called the Freiung, each forming a little town of itself. As in most Continental towns, the custom of living in flats is prevalent in Vienna, where few except the richer nobles occupy an entire house. Of late the so-called "Zinspaläste ("tenement palaces") have been built on a large and magnificent scale, often profusely adorned without and within with painting and sculpture. Some of the finest of these, a characteristic feature of Vienna architecture, are also to be seen in the old town. Other notable buildings within the line of the old fortifications are the Gothic Augustine church, containing a fine monument by Canova; the Capuchin church, with the burial vault of the Hapsburgs; the church of Maria-Stiegen, an interesting Gothic building of the 14th century; the handsome Greek church [restored], by Hansen; and the old rathhaus. At the corner of the Graben is the "Stock im Eisen," the stump of a tree, said to be the last survivor of a holy grove round which the original settlement of Vindomona sprang up (see p. 239 below). It is full of nails driven into it by travelling journeymen.

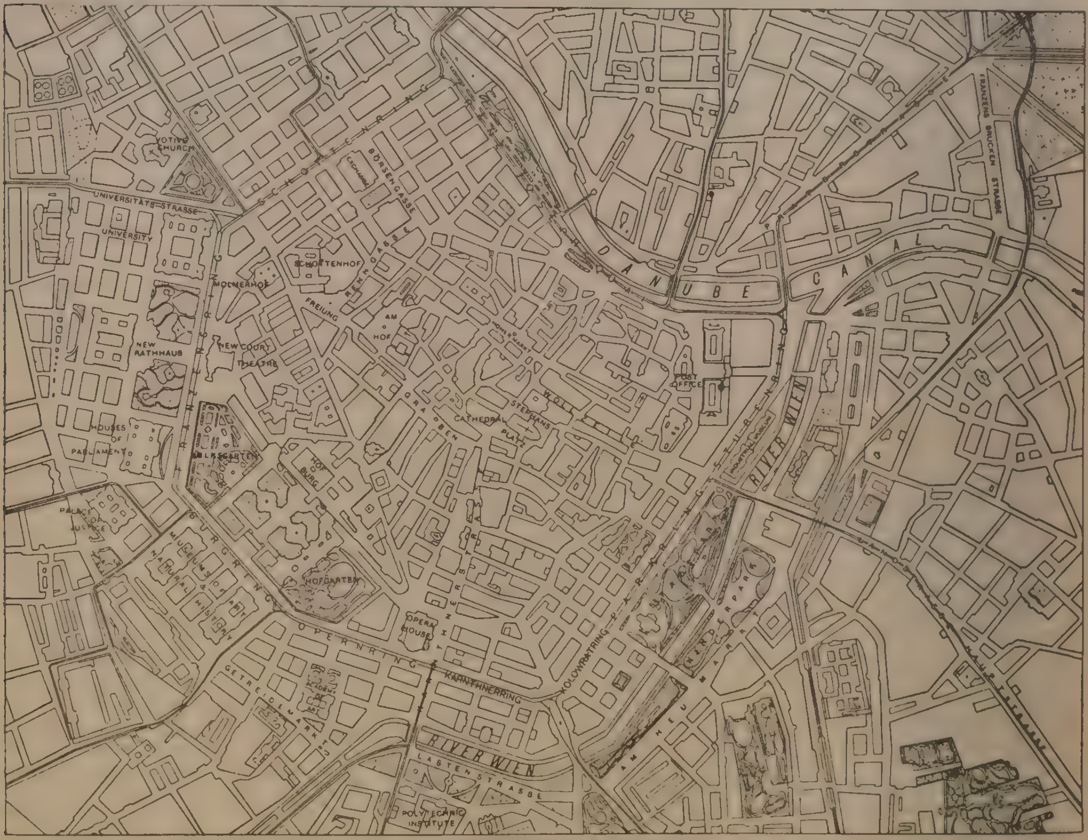
In the number of its large and handsome modern buildings Vienna can hold its own with any European capital. Most of these are found in or adjoining the Ring-Strasse, which certainly ranks as one of the most imposing achievements of recent street architecture. Opposite the Hofburg, the main body of which is separated from the Ring-Strasse by the Hofgarten and Volksgarten, rise the handsome monument of the Empress Maria Theresa and the imperial museums of art and natural history, two extensive Renaissance edifices with domes, matching each other in every particular and grouping finely with the new part of the palace.

---

[1] Some authorities connect the name of Vienna with Vindobona (see p. 239 below).

[2] [Imperial interments are not made in the catacombs, but their remains have been divided between some of the churches named below.—AM. ED.]

Hans Makart's painted dome in the natural history museum is the largest pictorial canvas in the world. Adjoining the museums to the west is the palace of justice (1881), and this is closely followed by the houses of parliament (1883), in which the Grecian style has been successfully adapted to modern requirements. Beyond the houses of parliament stands the new rathhaus, an immense and lavishly-decorated Gothic building, erected in 1873–83. It was designed by Friedrich Schmidt, who may be described as the chief exponent of the modern Gothic tendency, as Hansen and Semper, the creators respectively of the parliament house and the museums, are the leaders of the Classical and Renaissance styles which are so strongly represented in Viennese architecture. The central tower and the tapering steeple of the rathhaus are surmounted by a colossal bronze figure of a knight. Opposite the rathhaus, on the inner side of the Ring, is the new court theatre, another specimen of Semper's Renaissance work. To the north stands the new building of the university, a Renaissance structure by Ferstel, rivalling the rathhaus in extent. Near the university, and separated from the Ring by a garden, stands the votive church in Alsergrund, erected to commemorate the emperor's escape from assassination in 1853, one of the most elaborate and successful of modern Gothic churches, in which the efforts of the architect (Ferstel) are supported by a profusion of sculpture and stained glass windows. The other important buildings of the Ring-Strasse include the magnificent opera house, the sumptuous interior of which vies with that of Paris, the Academy of Art, the industrial museum, and the exchange. On the north side the Ring-Strasse gives place to the spacious Franz Joseph's quay, flanking the Danube Canal. The municipal districts outside the Ring also contain numerous handsome modern buildings. Among the churches may be instanced those of Wieden (St. Carlo Borromeo) and Lerchenfeld, the former an 18th-century imitation of St. Peter's at Rome, the latter a plain but graceful building in an early mediæval Italian style. The secular buildings include several large barracks and hospitals, various institutions connected with the university, the arsenal (with a collection of weapons), the Belvedere (see below), and the polytechnic institute, market-halls, etc. In the outlying districts are numerous villas of great taste and elegance.



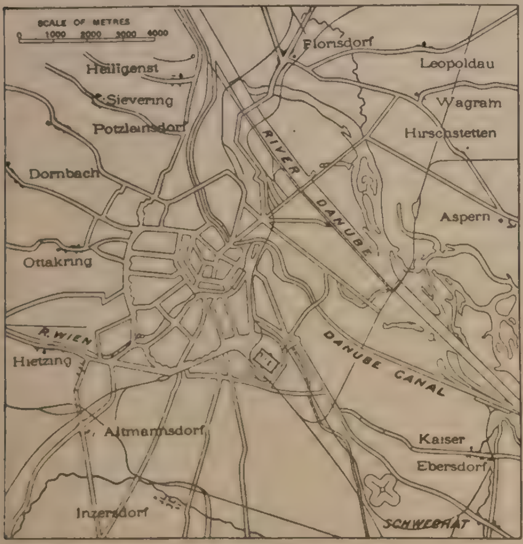
Plan of the city of Vienna.

Vienna is the intellectual as well as the material capital of Austria,—emphatically so in regard to the German part of the empire. Its university, established in 1365, is now attended by nearly 6000 students, and the medical faculty enjoys a world-wide reputation. Besides an adequate supply of elementary and secondary schools, the other educational institutions include a large polytechnic, an agricultural academy, a military school, Roman Catholic and Protestant theological seminaries, a conservatorium of music, a training school for aspirants to a diplomatic career, a commercial college, and numerous technical and special schools. Its scientific institutions are headed by the Academy of Science. The Academy of Art was founded in 1707. Few European capitals possess more valuable art collections than Vienna. The picture gallery in the Belvedere Palace, formerly the residence of Prince Eugene, is unsurpassed for its specimens of Rubens, Dürer, and the Venetian masters. The Lower Belvedere, at the other end of the garden, contains the famous Ambras collection of armor, curiosities, and antiquities. The private picture galleries of Prince Liechtenstein, Count Harrach, and Count Czernin are of great extent and importance; and the collection of drawings and engravings known as the "Albertina," in the palace of the archduke Albert, is familiar to all connoisseurs. The collections of the various museums, etc., which are not unworthy of the handsome buildings in which they are exhibited, and the extensive military collections of the arsenal must also be mentioned.

In 1880 the population of Vienna proper, *i.e.*, the ten municipal districts, amounted to 705,402, a number which gave it the fourth place among the cities of Europe. Including the suburbs, the total population rose to 1,082,812. The above figures are exclusive of the garrison of 20,700 men. The overwhelming majority of the inhabitants are Roman Catholics; the Jews numbered about 75,000, and the Protestants 26,500.

Owing to the peculiarities of its situation, the population of Vienna is of a very cosmopolitan and heterogeneous character. The German element is, of course, largely in the ascendant; but there are also large numbers of Czechs, Hungarians, and Slavs. As a general rule the Viennese are gay, pleasure-loving, and genial, and they possess a *bonhomie* which differentiates them markedly from the inhabitants of the other great German capital. The Viennese women are often distinguished by beauty and elegance; and dressing as a fine art is cultivated here with almost as great success as in Paris. As a rule the Viennese are passionately fond of dancing; and the city of Strauss, Lanner, and Gungl provides the civilized terpsichorean world with waltzes and polkas. Opera, especially in its lighter form, flourishes, and the actors of Vienna maintain with success a traditional reputation of no mean order. The above description must not be understood to convey a negation of more solid qualities, especially industry, frugality, and sobriety. Its chief place in the history of art Vienna owes to its musicians, among whom are counted Haydn, Mozart, Beethoven, and Schubert. The Viennese school of painting is of modern origin; but some of its members, for instance, Hans Makart, have acquired a European reputation.

The Prater, a vast expanse (2000 acres)[1] of wood and park on the east side of the city, between the Danube and the Danube Canal, is greatly frequented by all classes; and here all phases of Viennese life may be studied, from the fashionable corso in the Haupt-Allee in May down to the boisterous and Derby-day-like jollity of a Sunday in the Wurstel Prater or people's Prater. The great exhibition of 1873 was held in this park, and several of its buildings, including the large rotunda, have been left standing. Smaller parks are the Hofgarten, the Volksgarten, and the Town Park, all adjoining the Ring-Strasse. The environs of the city of Vienna contain many points of beauty and interest. Among the most popular resorts are the parks and gardens belonging to the imperial châteaux of Schönbrunn and Laxenburg.



Environs of Vienna.

The position of the city on the chief European waterway running from west to east early marked out Vienna as one of the great commercial emporia of eastern Europe. The valley of the March, which river here joins the Danube, forms a natural line of communication with the Oder and the Vistula. But the Austrian Government and the corporation of Vienna, by failing to keep the Danube in a proper state for navigation, have let slip the opportunity of making the city the great Danubian metropolis which its geographical position entitles it to be. An extensive trade is nevertheless carried on from Vienna in grain, partly as a direct importation from Hungary and partly in transit between Russia and southern Germany. Other important articles are wine, cattle, colonial wares, and manufactured goods of the most varied description. Though not conspicuous among cities of its own rank as an industrial centre, Vienna nevertheless carries on a considerable number of manufactures; and some of its products, such as its bentwood furniture and meerschaum pipes, are exported to all parts of Europe. In the number and variety of its leather and other fancy goods it rivals Paris; and among manufactures of a more solid character may be instanced machinery, ironwares, carriages, cotton and silk goods, etc. The beer of Vienna is also famous. The municipal government of Vienna is entrusted to a gemeinderath of 120 elected members, with an executive and police magistracy. The annual income of this body amounts to about one and a half million sterling [$7,290,000]. In the national parliament the city is represented by 10 members. The climate of Vienna is changeable, and rapid falls of temperature are not uncommon. The range between January and June is about 40° Fahr. Violent storms often occur in spring and autumn; and the heat of summer is accompanied by a plague of dust. Good water is brought by an aqueduct from the Schneeberg, 50 miles to the southwest. The annual death-rate is about twenty-six per thousand.

History. — For several centuries Vienna filled an important rôle as the most advanced bulwark of Western civilization and Christianity against the Turks, for during the whole of the Middle Ages Hungary practically retained its Asiatic character. The story of Vienna begins in the earliest years of the Christian era, with the seizure of the Celtic settlement of *Vindomona* by the Romans, who changed its name to *Vindobona*, and established a fortified camp here to command the Danube and protect the northern frontier of the empire. The fortress grew in importance, and was afterwards made a municipium; and here Marcus Aurelius died in 180. On the decline of the Roman empire Vindobona became the prey of successive barbarian invaders. Attila and his Huns were among the temporary occupants of the place (5th century), and in the following century it came into the possession of the Avars, after which its name disappears from history until towards the close of the 8th century, when Charlemagne expelled the Avars and made the district between the Enns and the Wiener Wald the boundary of his empire. In the time of Otho II. (976) this "East Mark" (Ostmark, Oesterreich, Austria) was granted in fief to the Babenbergers, and in the reign of Frederick Barbarossa (1156) it was advanced to the rank of a duchy. There is no certain record that the site of Vindobona was occupied at the time of the formation of the Ostmark, though many considerations make it probable. It is not likely that the Avars, living in their "ring" encampments, destroyed the Roman municipium; and Becs, the Hungarian name for Vienna to this day, is susceptible of a Slavonic interpretation only, and would seem to indicate that the site had been occupied in Slavonic times. The frequent mention of "Wiene" in the oldest extant version of the *Nibelungenlied* points in the same direction. Passing over a doubtful mention of "Vwienni" in the annals of 1030, we find the "civitas" of Vienna mentioned in a document of 1130, and in 1156 it became the capital and residence of Duke Heinrich Jasomirgott. In 1237 Vienna received a charter of freedom from Frederick II., confirmed in 1247. In the time of the crusades Vienna increased so rapidly, in consequence of the traffic that flowed through it, that in the days of Ottocar II. of Bohemia (1251–76), the successor of the Babenbergers, it had attained the dimensions of the present inner town. A new era of power and splendor begins in 1276,[2] when it became the capital of the Hapsburg dynasty, after the defeat of Ottocar by Rudolph of Hapsburg. From this time on it has shared the fortunes of the house of the Austria. In 1477 Vienna was besieged unsuccessfully by the Hungarians, and in 1485 it was taken by Matthew Corvinus. Of more importance were the two sieges by the Turks (1529 and 1683), when the city was saved on the first occasion by the gallant defence of Nicholas von Salm, and on the second by Rüdiger von Starhemberg, who held out until the arrival of the Poles and Germans under John Sobieski of Poland. The suburbs, however, were destroyed on both occasions. In 1805, and again in 1809, Vienna was for a short time occupied by the French. In 1814–15, it was the meeting-place of the congress which settled the political affairs of Europe after the overthrow of Napoleon. In 1848, the city was for a time in the hands of the revolutionary party; but it was bombarded by the imperial forces and compelled to surrender on 30th October of the same year. Vienna was not occupied by the Prussians in the war of 1866, but the invaders marched to within sight of its towers. Since then the most important event in its history has been the exhibition of 1873.

---

[1] [Bardeker gives an area of 4270 acres.—AM. ED.]

[2] [For the foundation of Vienna as the seat of a dynasty in 1282, see vol. iii., p. 108.—AM. ED.]

See Weiss, *Gesch. der Stadt Wien* (2 vols., 2d ed., 1882–83), containing an ample bibliography; *Oesterreich in Wort und Bild*, etc., *Erste Abth.* (1886); Weiss, *Topographie der Stadt Wien* (1876); Victor Tissot, *Vienne et la Vie Viennoise* (Paris, 1878). (J. F. M.)

VIENNE, a department of France, formed in 1790, out of Poitou (four-fifths of its present area), Touraine (one-seventh), and Berry, lies between 46° 3′ and 47° 10′ N. lat. and 0° 6′ W. and 1° 12′ E. long., and is bounded by Deux-Sèvres on the W., Charente on the S., Haute-Vienne on the S.E., Indre on the E., Indre-et-Loire on the N.E. and N., and Maine-et-Loire on the N.W. The river Vienne, which gives its name to the department, with its tributaries the Creuse (subtributary the Gartempe) on the east and the Clain on the west, flows from south to north. The general slope of the department is in the same direction, the highest point (764 feet) being in the southeast and the lowest (115 feet) at the junction of the Vienne and the Creuse. In the south the Charente, on the northwest the Dive, and in the west some streams belonging to the basin of the Sèvre-Niortaise drain small portions of the department. The average temperature is 54° Fahr. The prevailing winds are from the southwest and west. The annual rainfall is 23 inches.

Of the total area of 1,722,478 acres arable land occupies 1,119,675, grass 76,899, vines 90,750, woods 193,322, and heath, pasture, and uncultivated land 146,971. In 1881, the live stock included 22,637 horses, 7176 mules, 9679 asses, 63,052 cattle, 155,212 sheep of native and 47,970 of improved breed, 66,655 pigs, and 21,744 goats. There were also 11,047 beehives (32½ tons of honey and as much of wax). The crops in 1884 were—wheat 4,557,146 bushels, meslin 245,641, rye 291,673, barley 1,063,647, oats 4,295,742, buckwheat 27,813, maize 51,529, potatoes 3,455,220, beetroot 54,941 tons, colza seed 668 tons, hemp 323 tons, flax 3½ tons, hay 108,955 tons, clover 54,862, lucerne 98,282, sainfoin 53,350, other fodder 10,079 tons, wine 20,288,952 gallons (average for last ten years 21,384,880 gallons). Oak, ash, alder, and birch are the principal forest trees, and among the fruit-trees are the chestnut, walnut, and almond. Iron and manganese occur, and there are numerous quarries of building and lithographic stones, lime, limestone, mill-stones, marl, and a sort of pebbles which are cut into "Châtellerault diamonds." There are sulphur and iron mineral springs. The most important industrial establishments are the national arms manufactory and the cutlery works at Châtellerault; in other parts of the department are forges, blast furnaces, wool-spinning mills (580 spindles), hemp-spinning mills (4000 spindles, of which only 1500 are in use, and 28 looms), manufactories of serges and coarse cloth, vinegar, candles, leather, tiles, and pottery, paper-works, breweries, distilleries, rope-yards, lime-kilns, and numerous plaster and flour mills. Corn, wine, brandy, vegetables, fruit, chestnuts, fodder, cattle, cutlery, and dressed hides are exported; butcher's meat, colonial produce, and coals are imported. The department has 233 miles of railway, 239 of national and 8704 of other roads, and 32 of waterway (the Vienne from Châtellerault, the Dive below Moncontour, and some miles of the Creuse being navigable). The population in 1881 was 340,295 and in 1886 342,785, an increase of 101,795 since 1801. Vienne forms part of the diocese of Poitiers, has its court of appeal and academy at Poitiers, and belongs to the Tours army corps district. The chef-lieu is Poitiers (population 34,628 in 1886), and the department is divided for purposes of administration into five arrondissements (Poitiers; Châtellerault, population of town 14,498 in 1886; Civray, 2464; Loudun, 4041; Montmorillon, 4155), 31 cantons, and 300 communes.

VIENNE, a town of France, chef-lieu of an arrondissement in the department of Isère, historically and industrially the first, and by population the second, city of Dauphiné, is situated on the left bank of the Rhone, at the point where it is joined by the Gère, 19 miles S. of Lyons by the railway to Marseilles. On the north, east, and south the town is sheltered by low hills. Its site is an immense mass of ancient débris, which is constantly yielding interesting antiquities. Along the Gère are traces of the ramparts of the old Roman city; on Fort Pipet, to the east of the town, are the remains of a theatre and citadel and some vestiges of a pantheon and an amphitheatre; and in the interior of the town are two arches of a theatre and the balustrade of a magnificent staircase. The ancient aqueducts, restored in 1822, still convey the waters of the Gère from a distance of 4 or 5 miles; and there are several pieces of Roman road to be seen in the neighborhood. The Plan de l'Aiguille, a truncated quadrangular pyramid 55 feet high, resting on a portico with four arches, used to be pointed out as the tomb of Pontius Pilate (who, according to tradition, died here), but it is now recognized as having been part of the spina of a large circus, the outlines of which have been traced. The temple of Augustus and Livia, a rectangular building of the Corinthian order, was rebuilt at the end of the 2d century, and in the 5th century was converted into a church. The "festival of reason" was celebrated in it at the Revolution; and it has only lately been restored, and the houses built against it cleared away. The museum in the town-hall is very rich in antiquities. The cathedral of St. Maurice, exhibiting the finest Gothic architecture in Dauphiné, was begun at the end of the 12th century in the Transitional Burgundian style, on the ruins of a church which had been finished in 1107, and it was consecrated by Pope Innocent IV. in 1251. There is neither apse nor transept, and the building (315 feet long, 118 wide, and 89 high) is a singular mixture of the Romanesque and Gothic styles. The best part is the façade, finished in 1533, which rises majestically from a terrace overhanging the Rhone. Parts of the church of St. André-le-Bas, which was used as a chapel by the dukes of Burgundy, are as old as the 9th century, and most of it was built in 1152. The church of St. Peter, at present (1888) undergoing restoration, is one of the oldest in France, dating from the 6th century; the porch is in the most primitive Romanesque style; and the side walls, decorated with two rows of arches resting on marble columns (9th century), are unique in France. The steeple belongs to the 12th century, and the vaults were rebuilt by Soufflot in the 18th century. Among the many tombs is that of St. Mamert. In the square fronting the town-hall is a statue of Ponsard the dramatist, who was born at Vienne. The Gère supplies the motive power to numerous factories. About one million yards of cloth are annually produced, and from 8000 to 9000 hides are dressed. The other industrial establishments include a paper-mill, an iron and copper foundry (400 men), iron-works, foundries, lapidaries' workshops, glass-works, brick-works, and calcining and refining furnaces in connection with the lead and zinc mines in the neighborhood. Grain is an important article of commerce. A suspension bridge connects Vienne with the right bank of the Rhone, where the village of St. Colombe occupies part of the site of the ancient town. Near St. Romain-en-Gal is a tower built by Philip of Valois to defend the right, or French, bank, as distinguished from the left, which belonged to the empire. The population in 1881 was 22,740 (commune 26,060), and in 1886 23,011 (commune 25,480).

Vienne was originally the capital of the Allobroges, and was embellished and fortified by Julius Cæsar, who made it a colony. Tiberius granted the citizens the *jus Italicum*. The ramparts, pierced by five gates, enclosed a lower, middle, and upper town. Vienne was the residence of a prætor, had a senate, consuls, and a garrison of five legions, and was the seat of a celebrated school. A bridge of five arches connected it with the new town on the right bank. Postumus (see vol. xx. p. 794–5) was proclaimed Cæsar here in 259, and Vienne became the capital of a provincial empire, which under himself and his successors, Victorinus and Tetricus, lasted fourteen years. Christianity was introduced by St. Crescens in the 2d century, and St. Lupicin is named as the first archbishop. The archbishops of Vienne all through the Middle Ages disputed the title of primate of Gaul with those of Lyons. Vienne was conquered by the Burgundians in 438, and sacked by the Lombards in 558 and by the Saracens in 737. It was one of the residences of Boso, king of Burgundy and Provence (879), who died and was buried here. After the fall of the second kingdom of Burgundy, Vienne became the chef-lieu of a county, for which the nobility and clergy disputed, and which was finally seized by the counts of Albon. In 1349 Humbert II. ceded Vienne with all Dauphiné to France. The town was sacked in 1562 by Baron des Adrets, was claimed by both Roman Catholics and Protestants, but declared for the League in 1590, and was compelled to surrender to the duke of Montmorency, who destroyed the citadel and ramparts. The archbishopric was suppressed in 1790. Vienne was the birthplace of St. Julian (3d century); and pope Calixtus II. (Guy of Burgundy; *ob.* 1124) was one of its archbishops.

VIENNE, Haute-, a department of France, formed in 1790 out of Limousin (three-fifths), La Marche (one-fourth), Poitou, and Berry, and formerly known as Haut-Limousin, lies between 45° 26′ and 46° 23′ N. lat. and 0° 38′ and 1° 54′ E. long., and is bounded by the Indre on the N., Creuse on the E., Corrèze on the S.E., Dordogne on the S.W., Charente on the W., and Vienne on the N.W. Haute-Vienne belongs to the central plateau of France, and drains partly to the Loire and partly to the Garonne. The highest point (2549 feet) is in the extreme southeast, and belongs to the treeless but well-watered plateau of Millevaches, formed of granite, gneiss, and mica. To the northwest of the Millevaches are the Ambazac (2300 feet) and Blond (1690 feet) Hills, both separating the Valley of the Vienne from that of the Gartempe, a tributary of the Creuse. The Vienne traverses the department from east to west, passing Eymoutiers, St. Léonard, Limoges, and St. Junien, and receiving on the right the Maude and the Taurion. The Isle, which flows into the Dordogne, with its tributaries the Auvézère and the Dronne, and the Tardoire and the Bandiat, tributaries of the Charente, all rise in the south of the department. The altitude and inland position of Haute-Vienne, its geological character, and the northern exposure of its valleys make the winters long and severe; but the climate is milder in the west and northwest. The annual rainfall at Limoges is 36 inches.

Of the total area of 1,360,000 acres 439,215 are cultivated, 4263 are occupied by vineyards, 75,333 by chestnut trees, and 163,135 by dry underwood. The crops in 1884 were—wheat 1,242,271 bushels, meslin 34,298, rye 2,482,557, barley 13,300, oats 318,026, buckwheat 1,529,368, maize 65,579, potatoes 6,710,723, beetroot 189,000 tons, colza seed 1845 tons, hemp seed 1921, hemp 1200, linseed 93, flax 46, hay 387,192, clover 31,527, lucerne 3153, wine 111,430 gallons (average for preceding ten years 141,020 gallons). The live stock included 8371 horses of a shapely and powerful breed, 684 mules, 4975 asses, 146,131 cattle, 507,443 sheep of native and 43,593 of improved breed, 104,263 pigs, and 9642 goats. There were 36,601 beehives (104½ tons of honey and 34½ tons of wax). The department is on the whole unproductive. The chestnut is here characteristic, as the apple in Normandy, and with the potato and turnip it forms the chief food of the people. The brooks are fringed by fine meadows, and the hills are covered with heaths or forests of beech, hornbeam, oak, birch, and chestnut. The mineral wealth consists of iron, copper, tin, wolfram, antimony, serpentine, fine-grained granite, gneiss, garnets, emeralds, and a kind of porphyry, which takes a fine polish. There are inexhaustible supplies of china clay, in which an export trade is carried on with Russia and America. 5800 workmen are employed in porcelain manufactories, 650 in paper and pasteboard mills (annual product, £100,000 [$486,000]), 560 in wool and cotton spinning mills and manufactories of flannel, druggets, woollen cloaks, and carpets, 600 in shoemaking (annual product, £100,000 [$486,000]), 600 in manufactories of sabots, 340 in glove manufactories, 370 in tanyards, 325 in leather-dressing works, 130 in coach-building and wheelwrights' shops, 125 in cabinet workshops, 325 in printing works, and 100 in distilleries (annual product, £480,000 [$2,332,800]). In 1878 1153 tons of iron were produced, and there are forges, foundries, copper-works, and manufactories of agricultural and other implements. Porcelain, china clay, woven goods, boots and shoes, sabots, gloves, leather, cattle, horses, wood, chestnuts, hemp, and paper are exported; corn, wine, coal, raw materials, and various manufactured articles are imported. There are in Haute-Vienne 234 miles of railway, and 234 of national and 3191 of other roads. This department, with that of Corrèze, forms the diocese of Limoges; it belongs to the district of the Limoges court of appeal and army corps, has its academy at Poitiers, and is divided for purposes of administration into 4 arrondissements (Limoges, population of town 63,707 in 1886; Bellac, 4015; Rochechouart, 1829; and St. Yrieix, 3556), 27 cantons, and 203 communes. The population in 1881 was 349,332 and in 1886 363,182, an increase of 117,982 since 1801. Limoges is the chef-lieu. St. Yrieix has an early Gothic church of the 12th century, kaolin mines, porcelain manufactories, and tanyards. St. Junien (5454) has an interesting bridge and houses of the 13th century, and numerous manufactories of gloves, paper, porcelain, sabots, and woven goods. St. Léonard (3427), the birthplace of Gay-Lussac, possesses a remarkable church of the 11th and 12th centuries, tanyards, paper-mills, and copper-works. At Châlus (1675) Richard Cœur de Lion died.

VIERZON, a town of France, in the department of Cher, 124 miles by rail to the south of Paris. The Cher and the Yèvre unite at the foot of the hill on which lie the communes of Vierzon-Ville (population 10,514 in 1886) and Vierzon-Village (6995); Vierzon-Bourgneuf (1498) is on the left bank of the Cher. The three communes together have a population of 19,007. Vierzon has several large manufactories for the production of agricultural machines, also foundries, porcelain and earthenware works, and glass-works. A very fine technical school has just been opened.

VIETA, or Viète, François, Seigneur de la Bigotière (1540–1603), more generally known as Franciscus Vieta, mathematician, was born in 1540 at Fontenay-le-Comte, in Poitou. According to F. Ritter's investigations,[1] Vieta was brought up as a Catholic, and died in the same creed; but there can be no doubt that he belonged to the Huguenots for several years. On the completion of his studies in law at Poitiers Vieta began his career as an advocate in his native town. This he left about 1567, and somewhat later we find him at Rennes as a councillor of the parlement of Brittany. The religious troubles drove him thence, and Rohan, the well-known chief of the Huguenots, took him under his special protection. He recommended him in 1580 as a "maître des requêtes" (master of requests); and Henry of Navarre, at the instance of Rohan, addressed two letters to Henry III. of France on 3d March and 26th April, 1585, to obtain Vieta's restoration to his former office, but without result. After the accession of Henry of Navarre to the throne of France Vieta filled in 1589 the position of councillor of the parlement at Tours. He afterwards became a royal privy councillor, and remained so till his death, which took place suddenly at Paris in February, 1603, but in what manner we do not know; Anderson, the editor of his scientific remains, speaks only of a "præceps et immaturum autoris fatum."

We know of one important service rendered by Vieta as a royal officer. While at Tours he discovered the key to a Spanish cipher, consisting of more than 500 characters, and thenceforward all the dispatches in that language which fell into the hands of the French could be easily read. His fame now rests, however, entirely upon his achievements in mathematics. Being a man of wealth, he printed at his own expense the numerous papers which he wrote on various branches of this science, and communicated them to scholars in almost every country of Europe. An evidence of the good use he made of his means, as well as of the kindliness of his character, is furnished by the fact that he entertained as a guest for a whole month a scientific adversary, Adriaan van Roomen, and then paid the expenses of his journey home. Vieta's writings thus became very quickly known; but, when Franciscus van Schooten issued a general edition of his works in 1646, he failed to make a complete collection, although probably nothing of very great value has perished.

---

[1] *Bolletino Boncompagni*, vol. i. p. 227, note 1, Rome, 1868.

The form of Vieta's writings is what we may call their weak side. He indulged freely in flourishes; and in devising technical terms derived from the Greek he seems to have aimed at making them as unintelligible as possible. None of them, in point of fact, has held its ground, and even his proposal to denote unknown quantities by the vowels A, E, I, O, U, Y,—the consonants B, C, etc., being reserved for general known quantities, has not been taken up. In this denotation he followed, perhaps some older contemporaries, as Ramus, who designated the points in geometrical figures by vowels, making use of consonants R, S, T, etc., only when those were exhausted. Vieta is wont to be called the father of modern algebra. This does not mean, what is often alleged, that nobody before him had ever thought of choosing symbols different from numerals, such as the letters of the alphabet, to denote the quantities of arithmetic, but that he made a general custom of what until his time had been only an exceptional attempt. All that is wanting, in his writings, especially in his *Isagoge in artem analyticam* (1591), in order to make them look like a modern school algebra, is merely the sign of equality,—a want which is the more striking because Robert Recorde had made use of our present symbol for this purpose since 1557 and Xylander had employed vertical parallel lines since 1575. On the other hand, Vieta was well skilled in most modern artifices, aiming at a simplification of equations by the substitution of new quantities having a certain connection with the primitive unknown quantities. Another of his works, *Recensio canonica effectionum geometricarum*, bears a stamp not less modern, being what we now call an algebraic geometry,—in other words, a collection of precepts how to construct algebraic expressions with the use of rule and compass only. While these writings were generally intelligible, and therefore of the greatest didactic importance, the *principle of homogeneity*, first enunciated by Vieta, was so far in advance of his times that most readers seem to have passed it over without adverting to its value. That principle had been made use of by the Greek authors of the classic age; but of later mathematicians only Hero, Diophantus, etc., ventured to regard lines and surfaces as mere numbers that could be joined to give a new number, their sum. It may be that the study of such sums, which he found in the works of Diophantus, prompted him to lay it down as a principle that quantities occurring in an equation ought to be homogeneous, all of them lines, or surfaces, or solids, or supersolids, an equation between mere numbers being inadmissible. During the three centuries that have elapsed between Vieta's days and our own several changes of opinion have taken place on this subject, till the principle has at last proved so far victorious that modern mathematicians like to make homogeneous such equations as are not so from the beginning, in order to get values of a symmetrical shape. Vieta himself, of course, did not see so far as that; nevertheless the merit cannot be denied him of having indirectly suggested the thought. Nor are his writings lacking in actual inventions. He conceived methods for the general resolution of equations of the second, third, and fourth degrees different from those of Ferro and Ferrari, with which, however, it is difficult to believe him to have been unacquainted. He devised an approximate numerical solution of equations of the second and third degrees, wherein Leonardo of Pisa must have preceded him, but by a method every vestige of which is completely lost. He knew the connection existing between the positive roots of an equation (which, by the way, were alone thought of as roots) and the coefficients of the different powers of the unknown quantity. He found out the formula for deriving the sine of a multiple angle, knowing that of the simple angle with due regard to the periodicity of sines. This formula must have been known to Vieta in 1593. In that year Adriaan van Roomen gave out as a problem to all mathematicians an equation of the 45th degree, which, being recognized by Vieta as depending on the equation between $\sin \phi$ and $\sin \frac{\phi}{45}$, was resolved by him at once, all the twenty-three positive roots of which the said equation was capable being given at the same time. Such was the first encounter of the two scholars. A second took place when Vieta pointed to Apollonius's problem of taction as not yet being mastered, and Adriaan van Roomen gave a solution by the hyperbola. Vieta, however, did not accept it as there existed a solution by means of the rule and the compass only, which he published himself in his *Apollonius Gallus* (1600). In this paper Vieta made use of the centre of similitude of two circles. Lastly he gave an infinite product for the number π (see SQUARING THE CIRCLE, vol. xxii. p. 451).

Vieta's collected works were issued under the the title of *Opera Mathematica* by F. van Schooten at Leyden in 1646. (M. C. A.)

VIGEVANO, a town of Italy, in the province of Pavia, on the right bank of the Ticino, 24 miles south-west from Milan and about the same distance north-west from Pavia. It is a mediæval walled town, with an arcaded market-place, a cathedral, and a castle of the Sforza family, dating from the 14th century and adorned with a loggia by Bramante. It is a place of some importance in the silk trade, and also produces excellent macaroni. The population in 1881 was 14,794 (commune, 20,096).

VIGIL, in its ecclesiastical sense, means the day preceding a festival. In the liturgy of the Roman Catholic Church there are special offices for the vigils of the greater feasts, and the vigil is regarded as more or less of a fast day. In the early church there was a widespread practice of celebrating festivals, of martyrs especially, by actual vigils (*vigiliæ* or *pernoctationes*, παννυχίδες) in the churches; but this led to such serious evils that the custom had to be discouraged, and now survives, if at all, only in rare, unauthorized, and considerably disguised forms. In some of the stricter religious orders the daily office is recited at various hours of the night as well as during the day; but, if these nocturnal services are spoken of as vigils, it is only in the popular meaning of that word.

VIGILANTIUS, presbyter, celebrated as the author of a work, no longer extant, against superstitious practices, which called forth one of the most violent and scurrilous of Jerome's polemical treatises, was born about 370 at Calagurris in Aquitania (the modern Saint Bertrand de Comminges in the department of Haute-Garonne), where his father kept a "statio" or inn on the great Roman road from Aquitania to Spain. While still a youth his talent became known to Sulpicius Severus, who had estates in that neighborhood, and in 395 Sulpicius, who probably baptized him, sent him with letters to Paulinus of Nola, where he met with a friendly reception. On his return to Severus in Gaul he was ordained; and, having soon afterwards inherited means through the death of his father, he set out for Palestine, where he was received with great respect by Jerome at Bethlehem. The stay of Vigilantius lasted for some time; but, as was almost inevitable, he was dragged into the dispute then raging about Origen, in which he did not see fit wholly to adopt Jerome's attitude. On his return to the West he was the bearer of a letter from Jerome to Paulinus, and at various places where he stopped on the way he appears to have expressed himself about Jerome in a manner that when reported gave great offence to that father, and provoked him to write a reply (*Ep.*, 61). Vigilantius now settled for some time in Gaul, and is said by one authority (Gennadius) to have afterwards held a charge in the diocese of Barcelona. About 403, some years after his return from the East, Vigilantius wrote his celebrated work against superstitious practices, in which he argued against relic worship, as also against the vigils in the basilicas of the martyrs, then so common, the sending of alms to Jerusalem, and the attribution of special virtue to the unmarried state, especially in the case of the clergy. All that is known of this work is through Jerome's treatise *Contra Vigilantium*, or, as that controversialist would seem to prefer saying, "Contra Dormitantium." Notwithstanding Jerome's exceedingly unfavorable opinion, there is no reason to believe that the tract of Vigilantius was exceptionally illiterate, or that the views it advocated were different from those now held on the subjects with which it deals by most educated men outside the Roman Catholic Church, or even by many within its pale. Soon, however, the great influence of Jerome in the Western Church caused its leaders to espouse all his quarrels, and Vigilantius gradually came to be ranked in popular opinion among heretics. The year of his death is unknown.

VIGILIUS, pope from 537 to 555, succeeded Silverius and was followed by Pelagius I. He was ordained by order of Belisarius while SILVERIUS (*q.v.*) was still alive; his elevation was due to Theodora, who, by an appeal at once to his ambition and, it is said, to his covetousness, had induced him to promise to disallow the council of Chalcedon, in connection with the "three chapters" controversy (see vol. xiii. p. 805). When, however, the time came for the fulfilment of his bargain, Vigilius declined to give his assent to the condemnation of that council involved in the imperial edict against the three chapters, and for this act of disobedience he was peremptorily summoned to Constantinople, which he reached in 547. Shortly after his arrival there he issued a document known to history as his *Judicatum* (548), in which he condemned indeed the three chapters, but expressly disavowed any intentions thereby to disparage the council of Chalcedon. After a good deal of trimming (for he desired to stand well with his own clergy, who were strongly orthodox, as well as with the court) he prepared another document, the *Constitutum ad Imperatorem*, which was laid before the so-called fifth "œcumenical" council in 553, and led to his condemnation by the heterodox majority of that body, some say, even to his banishment. Ultimately, however, he was induced to assent to and confirm the decrees of the council, and was allowed after an enforced absence of seven years to set out for Rome. He died, however, before he reached his destination, most probably in the beginning of 555.

VIGNA, Pietro de la, or Petrus de Vinea (*c.* 1190–1249), the emperor Frederick II.'s minister, was born at Capua probably about 1190. From his own letters he would seem to have been of obscure parentage, though one of his correspondents refers to his *nobilitas*. He was perhaps educated at Bologna; but he certainly studied in a strange city and not at his own expense, though it is not till after his death that we find the story which makes him beg his bread in the streets. His name does not appear affixed to any judicial act before July, 1225, at which time he was *judex magnæ curiæ;* and this continued to be his official title till April, 1247, when his style was changed for that of protonotary and logothete. In 1232 he was at Rome on a mission to Gregory IX., and in 1234–35 he was in England negotiating the marriage of his master with Henry III.'s sister Isabella, after which time he seems to have kept up a friendly communication with the king, and on one occasion even begs to be reckoned "as a son and citizen of the realm." In March, 1239, he was with Frederick II. at Padua when the news came of the emperor's excommunication, with reference to which he was ordered to address the people. In 1247 he was at the very height of his power and regarded as the emperor's *alter ego*. But from this height of prosperity Peter suddenly fell very early in 1249, and all kinds of stories have been invented to explain an event that puzzled his contemporaries as well as succeeding ages. He was thrown into prison and blinded, after which he was led about from place to place as a public example, "the master-councillor of the emperor, who was lord of his law and betrayed him to the pope." His death must have taken place about April, 1249. There seems to be some truth in the tale that makes him die a suicide's death at Pisa. It is among the suicides that Dante meets his shade in hell.

Pietro de la Vigna's writings consist of (1) *Letters* and (2) a Latin poem on the twelve months of the year. A Latin satire directed against the Dominicans and Franciscans is also perhaps his. Besides these, many poems in the common speech are attributed to him. It is difficult to pronounce a definite opinion on his relation to the new religion or new church which it was perhaps the ambition of Frederick's most enthusiastic adherents to inaugurate. The *Letters* were first printed at Basel in 1566. See Huillard-Bréholles. *Vie et Correspondance de P. de la Vigne*, Paris, 1864.

VIGNOLA. See Barocchio.

VIGNY, Alfred de (1799–1863), a French poet of exceptionally refined and original faculty, which was kept from voluminous production by a fastidiousness perhaps verging on affectation, was born at Loches (Indre-et-Loire) on 27th March, 1799. Sainte-Beuve, in the rather ill-natured essay which he devoted to Vigny after his death, expresses a doubt whether the title of count which the poet bore was very well authenticated, and hints that no very ancient proofs of the nobility of the family were forthcoming; but it is certain that in the 18th century persons of the name occupied positions which were not open to any but men of noble birth. For generations the ancestors of Alfred de Vigny had been soldiers, and he himself joined the army at the age of sixteen. But the Revolutionary and Napoleonic wars were over, and after twelve years of life in barracks he retired, preserving, however, a very high estimate of the duties and career of the soldier. While still serving he had made his mark by the publication in 1822 of a volume of poems, and in 1826 by another, together with the famous prose romance of *Cinq-Mars*. Sainte-Beuve asserts that the poet antedated some of his most remarkable work. This may or may not be the case; he certainly did not and could not antedate the publication, and it so happens that some of his most celebrated books—*Eloa*, *Dolorida*, *Moïse*,—appeared before the work of younger members of the Romantic school whose productions strongly resemble these poems. It is quite certain that the other Alfred—Alfred de Musset—felt the influence of his elder namesake, and an impartial critic might discern no insignificant marks of the same effect in the work of Hugo himself. Even Lamartine, considerably Vigny's elder and his predecessor in poetry, seems rather to have been guided by Vigny than Vigny by him. No one can read *Dolorida* or *Le Cor* without seeing that the author had little to learn from any of his French contemporaries and much to teach them. At the same time Vigny, either from indolence, or from fastidiousness, or from being a "barren rascal," or from fear of losing the high position which he had gained, hardly attempted anything more in poetry proper during the more than thirty years of his life, and his entire poems, including posthumous fragments, form but one very small pocket volume. *Cinq-Mars*, which at least equalled the poems in popularity, will hardly stand the judgment of posterity so well. It had in its favor the support of the Royalist party, the immense vogue of the novels of Walter Scott, on which it was evidently modelled, the advantages of an exquisite style, and the taste of the day for the romance as opposed to the novel of analysis. It therefore gained a great name both in France and abroad. But any one who has read it critically must acknowledge it to be disappointing. The action is said to be dramatic; if it be so, it can only be said that this proves very conclusively that the action of drama and the action of the novel are two quite different things. To the reader who knows Scott or Dumas the story is singularly uninteresting (far less interesting than as told in history); the characters want life; and the book generally stagnates. Alfred de Vigny's admirable French and the quasi-poetical beauty of detached passages alone save it from positive dulness. Its author, though always as a kind of outsider (the phrase constantly applied to him in French literary essays and histories being that he shut himself up in a "tour d'ivoire"), attached himself more or less to the Romantic movement of 1830 and the years immediately preceding and following it, and was stimulated by this movement both to drama and to novel-writing. In the year before the revolution of July he produced at the Théâtre Français a translation or rather paraphrase of *Othello*, and an original piece, *Maréchale d'Ancre*. In 1832 he published the curious book *Stello*, and in 1835 he brought out his drama of *Chatterton*, which shocked French taste even after five years of Romantic education, by the hero's suicide, but had a considerable success. The same year saw the publication of *Servitude et Grandeur Militaires* a singular collection of sketches rather than a connected work, in which Vigny's military experience, his idea of the soldier's duties, and his rather poetical views of history were all worked in. The subjects of *Chatterton* and *Othello* naturally suggest a certain familiarity with English, and in fact Alfred de Vigny knew English well, lived in England for some time, and married an English woman. His father-in-law was, according to French gossip, so conspicuous an example of insular eccentricity that he never could remember his son-in-law's name or anything about him, except that he was a poet, by which fact and the kindness of casual Frenchmen who went through the list of the chief living poets of their country he was sometimes able to discover his daughter's husband's designation. In 1842 Alfred de Vigny was elected to the Academy, whose meetings he frequented with an assiduity rather surprising in a man of such retired habits and (still according to Sainte-Beuve) rather troublesome to his colleagues. But he produced nothing save a few scraps; and, beyond the work already enumerated, little has to be added except his *Journal d'un Poëte* and the poems called *Les Destinées*, edited, with a few fragments, by M. Louis Ratisbonne immediately after his death. Among his dramatic work, however, should be mentioned *Quitte pour la Peur* and an adaptation of the *Merchant of Venice* called *Shylock*. *Les Destinées* excited no great admiration in France, but they contain some exceedingly beautiful poetry of an austere kind, such as the magnificent speech of Nature in "La Maison du Berger" and the remarkable poem entitled "La Colère de Samson." Vigny died at Paris on 17th September, 1863.

The later life of Alfred de Vigny was almost wholly uneventful, and for the most part, as has been said, spent in retirement. His reputation, however, is perfectly secure. It may, and probably will, rest only on his small volume of poems, though it will not be lessened, as far as qualified literary criticism is concerned, should the reader proceed to the rest of the work. The whole of his non-dramatic verse does not amount to 5000 lines; it may be a good deal less. But the range of subject is comparatively wide, and extraordinary felicity of execution, not merely in language, but in thought, is evident throughout. Vigny, as may be seen in the speech of Nature referred to above, had the secret,—very uncommon with French poets,—of attaining solemnity without grandiosity, by means of an almost classical precision and gravity of form. The defect of volubility, of never leaving off, which mars to some extent his great contemporary Hugo, is never present in him, and he is equally free from the looseness and disorders of form which are sometimes blemishes in Musset, and from the effeminacy of Lamartine, while once more his nobility of thought and plentifulness of matter save him from the reproach which has been thought to rest on the technically perfect work of Théophile Gautier. The dramatic work is, perhaps, less likely to interest English than French readers, the local color of *Chatterton* being entirely false, the sentiment conventional in the extreme, and the real pathos of the story exchanged for a commonplace devotion on the poet's part to his host's wife. In the same way, the finest passages of *Othello* simply disappear in Vigny's version. In his remaining works the defect of skill in managing the plot and characters of prose fiction, which has been noticed in *Cinq-Mars* reappears, together (in the case of the *Journal d'un Poëte* and elsewhere) with signs of the fastidious and slightly affected temper which was Vigny's chief fault as a man. In his poems proper none of these faults appear, and he is seen wholly at his best. It should be said that of his posthumous work not a little had previously appeared piecemeal in the *Revue des Deux Mondes*, to which he was an occasional contributor. The prettiest of the complete editions of his works (of which there are several) is to be found in what is called the *Petite Bibliothèque Charpentier*. (G. SA.)

VIGO, a town of Spain, in the province of Pontevedra, 486 miles by rail northwest from Madrid, is picturesquely situated on the side of a hill (Castelo) which slopes down to the southern shore of the Ria de Vigo. The Ria is the most southerly of the great fjords by which the western coast of Galicia is so deeply indented; Bayona at its mouth is 13 miles from the town of Vigo and Puente Sampayo at its head a somewhat shorter distance. Some of the former walls still remain, and there are two old castles on the hill behind the town; the older streets retain their narrow, steep, and tortuous aspect. There are some fisheries at Vigo; but the manufactures of the place are insignificant. Its activity is entirely due to its magnificent anchorage; it is a regular port of call for several international lines of steamers, and has a very important trade; the chief imports are cotton and woollen fabrics, sugar, hides, etc., while cattle, sardines, grain, and eggs are exported. The population within the municipal limits in 1877 was 13,416.

Vigo, the ancient Οὔικα (Ptolemy) or *Vicus Spacorum*, has in modern times been more than once attacked by the English,—by Drake in 1585 and 1589, and by Cobham in 1719. The Plate fleet was destroyed by the duke of Ormond and admirals Rooke and Stanhope in Vigo Bay on 22d October, 1702.

VILKOMIR, or **WILKOMIERZ**, a district-town of Russia, in the government of Kovno, 44 miles northeast of the capital of the province, is one of the oldest cities in that part of western Russia. Founded as early as 1025, it suffered much from the attacks of the Teutonic Knights, as well as from internal wars. It flourished in the 16th century under "Magdeburg law," but soon came upon adverse times again during the wars between Poland, Russia, and Sweden. It was annexed to Russia in 1796. Its position on the principal highway from St. Petersburg to Kovno gave it some trade in flax, but this is now declining. Its population increased from 7300 in 1860 to 16,240 in 1885. Vilkomir has a fine church dating from the 14th century.

VILLA DE CONTAS, a town of Brazil, in the province of Bahia, 230 miles southwest from the city of Bahia, on the Brumado (Contas-Pequeno), a headstream of the Rio de Contas (Jussiape), which rises on the east slope of the neighboring Serra das Almas, and flows thence to the coast at Barra do Rio Contas. This town, which has a mixed population (1880) of 10,200 whites, Negroes, halfcastes, and Indians, lies in a fertile district producing much cotton, sugar, and tobacco. It was founded in 1715 by some enterprising "Paulistas," who were attracted to the district by the auriferous sands washed down by the head-streams of the Jussiape. It received the title of a town in 1724, and soon afterwards most of the inhabitants removed to the present more convenient site five miles lower down the Brumado, on the high road between Bahia and Goyaz. Villa de Contas is the capital of the department of the same name, which was detached in 1833 from the old department of Jacobina.[1]

VILLA DO RIO PARDO, a town of Brazil, in the province of Rio Grande do Sul, on the left bank of the Jacuhy at its confluence with the Pardo, about 80 miles due west from Porto Alegre, in 30° S. lat. and 52° W. long. The Jacuhy, chief affluent of the coast lagoon Dos Patos, is navigable by small steamers to this place, which is one of the most flourishing towns in the province, with a total population (1880) of 11,500, including 6000 whites, 4500 Negroes and colored, and about 1000 civilized Indians. It had its origin in a fort built by the Portuguese at this point in 1751, but was not raised to the rank of a town till 1809. There is a large parish church, founded in 1769, besides several other churches and three schools, but no noteworthy buildings. The district is fertile and well watered, and grows an excellent flax, which supplies a number of local hand-looms. A considerable export trade is carried on by the river craft, which here ship maté (Paraguay tea), jerked meat, linen, and other products for the coast towns.

VILLANI, **GIOVANNI** (*c.* 1275–1348), Italian chronicler, was the son of Villano di Stoldo, and was born at Florence in the second half of the 13th century; the precise year is unknown. He was of good burgher extraction, and, following the traditions of his family, applied himself to commerce. During the early years of the 14th century he travelled in Italy, France, and the Netherlands, seeing men and things with the sagacity alike of the man of business and of the historian. Before leaving Florence, or rather in the interval between one journey and another, he had at least taken some part in that troubled period of civil contentions which Dino Compagni has described, and which swept Dante Alighieri into banishment. In 1301 Villani saw Charles of Valois ruining his country under the false name of peacemaker, and was witness of all the misery which immediately followed.[1] Somewhat later he left Italy, and in September, 1304, he visited Flanders. It is not well ascertained when he returned to his native city. He was certainly living there shortly after the emperor Henry VII. had come to Italy in 1312, and probably he had been there for some time before. While still continuing to occupy himself with commerce, he now began to take a prominent part in public affairs. In 1316 and 1317 he was one of the priors, and shared in the crafty tactics whereby Pisa and Lucca were induced to conclude a peace with Florence, to which they were previously averse.[2] In 1317 he also had charge of the mint, and during his administration of this office he collected its earlier records and had a register made of all the coins struck in Florence up to his day. In 1321 he was again chosen prior; and, the Florentines having just then undertaken the rebuilding of the city walls, he and some other citizens were deputed to look after the work. They were afterwards accused of having diverted the public money to private ends; but Villani clearly established his innocence. He was next sent with the army against Castruccio Castracane, lord of Lucca, and was present at its defeat at Altopascio. In 1328 a terrible famine visited many provinces of Italy, including Tuscany, and Villani was appointed to guard Florence from the worst effects of that distressing period. He has left a record of what was done in a chapter of his *Chronicle*, which still remains a monument of the economic wisdom in which the mediæval Florentines were often so greatly in advance of their age.[3] In 1339, some time after the death of Castruccio, some rich Florentine merchants, and among them Villani, treated for the acquisition of Lucca by Florence for 80,000 florins [$203,355.80], offering to supply the larger part of that sum out of their own private means; but the negotiations fell through, owing to the discords and jealousies then existing in the Government (*Chron.*, x. 143). The following year Villani superintended the making of Andrea Pisano's bronze doors of the baptistery (see vol. xix. p. 131). In the same year he watched over the raising of the campanile of the Badia, erected by Cardinal Giovanni Orsini (*Chron.*, x. 177). In 1341 the acquisition of Lucca was again under treaty, this time with Martino della Scala, for 250,000 florins [$635,452.50]. Villani was sent with others as a hostage to Ferrara, where he remained for some months (xi. 130, 133, 135). He was present in Florence during the unhappy period that elapsed between the entry of the duke of Athens and his expulsion by the Florentines (xii. 1, 2, 8, 15, 16). Involved through no fault of his own in the failure of the commercial company of the Bonaccorsi, which in its turn had been drawn into the failure of the company of the Bardi (1345), Villani towards the end of his life suffered much privation and for some time was kept in prison.[4] In 1348 he fell a victim to the plague described by Boccaccio.

---

[1] Ritter, and with him nearly all other geographers, wrongly make this place still the capital of Jacobina, although Millet de Saint-Adolphe (ii. p. 404) distinctly makes the statement given in the text.

The idea of writing the *Chronicle* was suggested to Villani under the following circumstances: "In the year of Christ 1300 Pope Boniface VIII. made in honor of Christ's nativity a special and great indulgence. And I, finding myself in that blessed pilgrimage in the holy city of Rome, seeing her great and ancient remains, and reading the histories and great deeds of the Romans as written by Virgil, Sallust, Lucan, Livy, Valerius, Paulus Orosius, and other masters of history who wrote the exploits and deeds, both great and small, of the Romans and also of strangers in the whole world . . . considering that our city of Florence, the daughter and offspring of Rome, is on the increase and destined to do great things, as Rome is in her decline, it appeared to me fitting to set down in this volume and new chronicle all the facts and beginnings of the city of Florence, in as far as it has been possible to me to collect and discover them, and to follow the doings of the Florentines at length . . . and so in the year 1300, on my return from Rome, I began to compile this book in honor of God and of the blessed John, and in praise of our city of Florence."[5] Villani's work, written in Italian, makes its appearance, so to say, unexpectedly in the historical literature of Italy, just as the history of Florence, the moment it emerges from the humble and uncertain origin assigned to it by legend, rises suddenly into a rich and powerful life of thought and action. Nothing but scanty and partly legendary records had preceded Villani's work, which rests in part on them. The *Gesta Florentinorum* of Sanzanome, starting from these vague origins, begins to be more definite about 1125, at the time of the union of Fiesole with Florence. The *Chronica de Origine Civitatis* seems to be a compilation, made by various hands and at various times, in which the different legends regarding the city's origin have been gradually collected. The *Annales Florentini Primi* (1110–1173) and the *Annales Florentini Secundi* (1107–1247), together with a list of the consuls and podestas from 1197 to 1267, and another chronicle, formerly attributed, but apparently without good reason, to Brunetto Latini, complete the series of ancient Florentine records. To these must, however, be added a certain quantity of facts which were to be found in various manuscripts, being used and quoted by the old Florentine and Tuscan writers under the general name of *Gesta Florentinorum.* Another work which used to be reckoned among the sources of Villani is the *Chronicle of the Malespini;* but very grave doubts are now entertained as to its authenticity, and many hold that at best it is merely a remodelling, posterior to Villani's time, of old records unknown to us, from which several chroniclers may have drawn, either without citing them at all or only doing so in a vague manner. The *Cronaca Fiorentina* of Villani goes back to Biblical times and comes down to 1346. The wide universality of the narrative, especially in the times near Villani's own, while it bears witness to the author's extensive travels and to the comprehensiveness of his mind, makes one also feel that the book was inspired within the walls of the universal city. Whereas Dino Compagni's *Chronicle* is confined within definite limits of time and place, this of Villani is a general chronicle extending over the whole of Europe. Dino Compagni feels and lives in the facts of his history; Vallani looks at them and relates them calmly and fairly, with a serenity which makes him seem an outsider, even when he is mixed up in them and is himself their originator. While very important for Italian history in the 14th century, this work is the corner stone of the early mediæval history of Florence. Of contemporary events Villani has a very exact knowledge. Having been a sharer in the public affairs, and in the intellectual and economic life, of his native city, at a time when in both it had no rival in Europe, he depicts what he saw with the vividness natural to a clear mind accustomed to business and to the observation of mankind. He was Guelph, but without passion; and his book is much more taken up with an inquiry into what is useful and true than with party considerations. He is really a chronicler, not an historian, and has but little method in his narrative, often reporting the things which occurred long ago and far off just as he heard them and without criticism. Every now and then he falls into some inaccuracy; but such defects as he has are largely compensated for by his valuable qualities. He was for half a century eye-witness of his history, and provides abundant information on the constitution of Florence, its customs, industries, commerce, and arts; and among the chroniclers throughout Europe he is perhaps unequalled for the value of the statistical data he has preserved. As a writer Villani is clear and acute; and, though his prose has not the force and coloring of Compagni, it has the advantage of greater simplicity, so that taking his work as a whole he may be regarded as the greatest chronicler who has written in Italian. The many difficulties connected with the publication of this most important text have hitherto prevented the preparation of a perfect edition. The Italian Historical Institute, lately founded, has, however, undertaken to reprint on a wider scheme the great collection of Muratori.

[1] See Villani, *Chronicle*, bk. viii. ch. 37, 38.

[2] *Chron.*, bk. ix. ch. 80.

[3] *Chron.*, bk. x. ch. 121.

[4] On Vallani's imprisonment, see Massai's biography of Villani, mentioned below.

[5] *Chron.*, bk. viii. ch. 36.

Vallani's *Chronicle* was continued by two other writers of the same name. (1) MATTEO VILLANI, his brother, of whom nothing is known save that he was twice married, and that he died of the plague in 1363, continued it down to the year of his death. Matteo's work, though inferior to Giovanni's, is nevertheless very valuable. A more prolix writer than his brother and a less acute observer, Matteo is well informed in his facts, and for the years of which he writes is one of the most important sources of Italian history. (2) FILIPPO VILLANI, the son of Matteo, flourished in the end of the 14th and the beginning of the 15th century. In his continuation, though showing greater literary ability, he is very inferior as an historian to his predecessors. His most valuable work was a collection of lives of illustrious Florentines. Twice, in 1401 and 1404, he was chosen to explain in public the *Divina Commedia* in the Florentine "studio." The year of his death is unknown.

On Giovanni Villani, as well as on Matteo and Filippo, the following books may be consulted: Argelati, *Bibl. Mediol.* (1745); U. Balzani, *Early Chroniclers of Italy* (1883); Bellarmin-Labbé, *Script. eccl.* (1728); Brunet, *Manuel* (1864); *Classici Ital.* (1802); Fabricius, *Bibl. Med. Æv.* (1735); Gamba, *Testi Ital.* (1828); Gervinus, *Hist. Schrift.* (1833); Giovanni e Mira (Ant. di), in *Giorn. di Scienze*, xxxi; Graesse, *Trésor* (1867); Hartwig (Otto), "Giovanni Villani und die Leggenda di Messer Gianni di Procida," in Sybel, *Histor. Zeitschr.* (1871); Id., *Quellen und Forschungen zur ältesten Geschichte der Stadt Florenz* (1870); V. Le Clerc, in *Hist. Litt. France* (1862); Lorenz, *Deutsch. Geschichtsquellen* (1870); Massai (Pietro), in *Uom. Ill. Toscani* (1771); Melzi, *Anon. Ital.* (1852); Michaud, *Bibl. des Croisades* (1829); Milanesi (Gaet.), "Documenti riguardanti G. Villani e il Palazzo degli Alessi in Siena," in *Arch. Stor. Ital.* (1856); Moreni, *Bibl. Toscana* (1805); Muratori, *Rer. Ital. Script.*; Negri, *Scritt. Fiorent.* (1722); *Rev. de Paris* (1832); and Tiraboschi, *Stor. Lett. Ital.* (1807). (U. B.)

VILLARS, CLAUDE LOUIS HECTOR, DUKE OF (1653–1734), French general, was born at Moulins on 8th May, 1653. After spending some time at the college of Juilly, he became a page of the *grand écurie*, and then entered the army as a volunteer. He first saw service in Holland under Louis XIV. and later under Condé, Turenne, and Luxembourg in Germany, where in 1674 he obtained the command of a troop of horse. Hostilities being brought to a close by the peace of Nimeguen in 1678, he was sent as ambassador to the courts of Vienna and Munich, in which capacity he greatly distinguished himself. In 1702 he received the command of an army in order to succor the elector of Bavaria, who had espoused the cause of France in the war of Succession. On 14th October he routed at Friedlingen Louis of Baden, the Austrian commander. In the beginning of the following year he captured Kehl and effected a junction with the army of the elector. He then conceived the daring project of marching on Vienna. The united forces defeated the Austrians under Count Styrum at Hochstädt, but his skilfully conceived project, which had every prospect of success owing to the scattered state of the Austrian forces, had to be abandoned on account of the pusillanimous conduct of the elector. Villars was next sent to subdue the Camisards, the Protestants of the Cevennes, a task which he completed by a judicious combination of military skill and clemency. In 1705 the northeastern frontier, which was threatened by Marlborough, was defended by Villars with such skill and ability that Marlborough was completely baffled in his attempts to penetrate into France, and even compelled to retreat. Villars took advantage of this opportunity to march into Alsace, where he captured several towns along with great quantities of war materials belonging to Marlborough and Prince Eugene. These advantages were, however, counterbalanced by Villeroy's defeat at Ramillies. After two short campaigns in 1707–8 Villars was sent (in 1709) to Flanders to oppose Marlborough and Prince Eugene. He was, however, defeated at Malplaquet and severely wounded. The weak state of his health, the consequence of his wound, prevented him during the next two years from engaging in active service. In 1712 Villars, at the head of an army raised with great difficulty by the French, defeated the Austrians under Albemarle in a brilliant action at Denain, compelled Prince Eugene to raise the siege of Landrecies, and took several fortresses and towns. This brilliant campaign raised again the almost desperate fortunes of France and led to the treaty of Utrecht (1713) and the peace of Rastadt (1714). For many years after this Villars exerted great influence at court, until he was finally supplanted by Fleury. In 1733 the war with Austria again broke out, and in the following year Villars, although over eighty years of age, was sent to take command in Italy. But after some successes he demanded his recall, either in consequence of his increasing infirmities or of disgust at the conduct of his ally, the king of Sardinia; he died on his way back to France, at Turin, on 17th June, 1734.

VILLEFRANCHE DE ROUERGUE, a town of France, chef-lieu of an arrondissement in the department of Aveyron, is situated 390 miles south of Paris by the railway to Toulouse, on the right bank of the Aveyron. One of the three bridges that cross the river belongs to the 13th century, and the narrow, winding streets are full of gabled houses of the 13th and 14th centuries. The church of Notre Dame (1260–1581) has a nave and two fine rose windows of the 14th and 15th centuries. The steeple is represented by an unfinished square tower (190 feet). In the interior the stone pulpit, the rich woodwork of the choir, and tapestry of the 16th century are worthy of notice. Some parts of the Carthusian monastery, now used as a hospital, belong to the 15th and 16th centuries. The little cloister is a masterpiece of the best period of Gothic; the fine pulpit of the refectory and the Gothic architecture of some of the rooms have been preserved. Rich quarries of phosphates are worked near Villefranche. The population in 1881 was 8433 (commune 10,366), and in 1886 8092 (commune 9836).

Villefranche, founded about 1252, owes its name to the numerous immunities granted by Alphonse of Poitiers, count of Toulouse. In 1348 it was so flourishing that sumptuary laws were passed. The town fell into the hands of the Black Prince, but was the first place in Guienne to rise against the English. Charles V. granted it new privileges, which were taken away by Louis XI. In 1588 the inhabitants repulsed the League, and afterwards murdered a governor sent by Henry IV. The town was ravaged by the plague in 1463, 1558, and 1628. A revolt excited by the exactions of the intendants was cruelly repressed in 1643. Villefranche was the birthplace of Marshal de Belle-Isle.

VILLEFRANCHE-SUR-SAÔNE, a commercial and manufacturing town of France, chef-lieu of an arrondissement in the department of Rhone, is situated on the Morgon, near its junction with the Saône, 18 miles by rail nearly north of Lyons. The chief industrial establishments are factories of coarse woven goods, cotton, fustian, "molletons," prints, and blankets, tan-yards, puddling-works, spinning-mills, distilleries, foundries, and a saw-mill. The wines of Beaujolais, hemp, cloth, linen, cottons, drapery goods, and cattle are the principal articles of trade. An old Renaissance house is used as the town-hall. The church of Notre Dame des Marais, begun at the end of the 14th and finished in the 16th century, has a tower and spire (rebuilt in 1862), standing to the right of the façade (15th century), in which are carved wooden doors. Villefranche is the seat of the primary normal school of the department. The population, 12,032 (commune 13,074) in 1881, was 12,157 (commune 12,518) in 1886.

The town grew up near a tower from which the lords of Beaujeu enforced their rights of toll on the Burgundy and Lyons road. The name arose out of privileges granted by Guichard I. of Beaujeu, which were confirmed and extended by his successors. Under the dukes of Burgundy Villefranche was the capital of Beaujolais, and retained some of its privileges when united to France. Baron des Adrets sacked the town and demolished the ramparts in 1562. A well-known academy was founded here in 1695.

VILLEHARDOUIN, GEOFFROY DE (*c.* 1160–*c.* 1213), the first vernacular historian of France, and perhaps of modern Europe, who possesses literary merit is rather supposed than known to have been born at the Château from which he took his name, near Troyes in Champagne, about the year 1160. Not merely his literary and historical importance, but almost all that is known about him comes from his chronicle of the fifth crusade, or *Conquête de Constantinople.* Nothing is positively known of his ancestry, for the supposition (originating with Du Cange) that a certain William, marshal of Champagne between 1163 and 1179, was his father appears to be erroneous. Villehardouin himself, however, undoubtedly held this dignity, and certain minute and perhaps not very trustworthy indications, chiefly of an heraldic character, have led his most recent biographers to lay it down that he was not born earlier than 1150 or later than 1164. He introduces himself to us with a certain abruptness, merely specifying his own name as one of a list of knights of Champagne who with their count, Thibault, took the cross at a tournament held at Escry-sur-Aisne at Advent, 1199, the crusade in contemplation having been started by the preaching of Fulk de Neuilly, who was commissioned thereto by Pope Innocent III. The next year six deputies, two appointed by each of the three allied counts of Flanders, Champagne, and Blois, were despatched to Venice to negotiate for ships. Of these deputies Villehardouin was one and Quesnes de Béthune, the poet, another. They concluded a bargain with the seigniory for transport and provisions at a fixed price. Villehardouin had hardly returned when Thibault fell sick and died; but this did not prevent, though it somewhat delayed, the enterprise of the crusaders. The management of that enterprise, however, was a difficult one, and cost Villehardouin another embassy into Italy to prevent, if possible, some of his fellow-pilgrims from breaking the treaty with the Venetians by embarking at other ports and employing other convoy. He was only in part successful, and there was great difficulty in raising the charter-money among those who had actually assembled (in 1202) at Venice, the sum collected falling far short of the stipulated amount. It is necessary to remember this when the somewhat erratic and irregular character of the operations which followed is judged. The defence that the crusaders were bound to pay their passage-money to the Holy Land in one form or other to the Venetians is perhaps a weak one in any case for the attack on two Christian cities, Zara and Constantinople; it becomes weaker still when it is found that the expedition never went or attempted to go to the Holy Land at all. But the desire to discharge obligations incurred is no doubt respectable in itself, and Villehardouin, as one of the actual negotiators of the bargain, must have felt it with peculiar strength.

The crusaders set sail at last, and Zara, which the Venetians coveted, was taken without much trouble. The question then arose whither the host should go next. Villehardouin does not tell us of any direct part taken by himself in the debates on the question of interfering or not in the disputed succession to the empire of the east,—debates in which the chief ecclesiastics present strongly protested against the diversion of the enterprise from its proper goal. It is quite clear, however, that the marshal of Champagne, who was one of the leaders and inner counsellors of the expedition throughout, sympathized with the majority, and it is fair to point out that the temptation of chivalrous adventure was probably as great as that of gain. He narrates spiritedly enough the dissensions and discussions in the winter camp of Zara and at Corfu. but is evidently much more at ease when the voyage was again resumed. and, after a fair passage round Greece, the crusaders at last saw before them the great city of Constantinople which they had it in mind to attack. When the assault was decided upon, Villehardouin himself was in the fifth "battle," the leader of which was Mathieu de Montmorency. But, though his account of the siege is full of personal touches, and contains one reference to the number of witnesses whose testimony he took for a certain wonderful fact, he does not tell us anything of his own prowess. After the flight of the usurper Alexius, and when Isaac, whose claims the crusaders were defending, had been taken by the Greeks from prison and placed on the throne, Villehardouin, with Montmorency and two Venetians, formed the embassy sent to arrange terms. He was again similarly distinguished when it became necessary to remonstrate with Alexius, the blind man's son and virtual successor, on the non-keeping of the terms. Indeed Villehardouin's talents as a diplomatist seem to have been held in very high esteem, for later, when the Latin empire had become a fact, he was charged with the delicate business of mediating between the emperor Baldwin and Boniface, marquis of Montferrat, in which task he had at least partial success. He was also appointed marshal of "Romanie"—a term very vaguely used, but apparently signifying the mainland of the Balkan Peninsula, while his nephew and namesake, afterwards prince of Achaia, took a great part in the Latin conquest of Peloponnesus. Villehardouin himself before long received an important command against the Bulgarians. He was left to maintain the siege of Adrianople when Baldwin advanced to attack the relieving force, and with Dandolo had much to do in saving the defeated crusaders from utter destruction, and conducting the retreat, in which he commanded the rear guard, and brought his troops in safety to the sea at Rodosto, and thence to the capital. As he occupied the post of honor in this disaster, so he had that (the command of the vanguard) in the expedition which the regent Henry made shortly afterwards to revenge his brother Baldwin's defeat and capture. And, when Henry had succeeded to the crown on the announcement of Baldwin's death, it was Villehardouin who fetched home his bride Agnes of Montferrat, and shortly afterwards commanded under him in a naval battle with the ships of Theodore Lascaris at the fortress of Cibotus. In the settlement of the Latin empire after the truce with Lascaris Villehardouin received the fief of Messinople (supposed to be Mosynopolis, a little inland from the modern gulf of Lagos, and not far from the ancient Abdera) from Boniface of Montferrat, with the record of whose death the chronicle abruptly closes.

In the foregoing account only those particulars which bear directly on Villehardouin himself have been detailed; but the chronicle is as far as possible from being an autobiography, and the displays of the writer's personality, numerous as they are, are quite involuntary, and consist merely in his way of handling the subject, not in the references, as brief as his functions as chronicler will admit, to his own proceedings. The chronicle of Villehardouin is justly held to be the very best presentation we possess of the spirit of chivalry, not the designedly exalted and poetized chivalry of the romances, not the self-conscious and deliberate chivalry of the 14th century, but the unsophisticated mode of thinking and acting which brought about the crusades, stimulated the vast literary development of the 12th and 13th centuries, and sent knights-errant, principally though not wholly of French blood, to establish principalities and kingdoms throughout Europe and the near East. On the whole, no doubt, it is the more masculine and practical side of this enthusiastic state of mind which Villehardouin shows. No woman makes any but the briefest appearance in his pages, though in reference to this it must of course be remembered that he was certainly a man past middle life when the events occurred, and perhaps a man approaching old age when he set them down. Despite the strong and graphic touches here and there, exhibiting the impression which the beauty of sea and land, the splendor of Constantinople, the magnitude of the effete but still imposing Greek power made on him, there is not only an entire absence of dilation on such subjects as a modern would have dilated on (that was to be expected), but an absence likewise of the elaborate and painful description of detail in which contemporary *trouvères* would have indulged. It is curious, for instance, to compare the scanty references to the material marvels of Constantinople which Villehardouin saw in their glory, which perished by sack and fire under his very eyes, and which live chiefly in the melancholy pages of his Greek contemporary Nicetas, with the elaborate descriptions of the scarcely greater wonders of fabulous courts at Constantinople itself, at Babylon, and elsewhere to be found in his other contemporaries, the later *chanson de geste* writers and the earlier embroiderers of the Arthurian romances and *romans d'aventures.* And this latter contrast is all the more striking that Villehardouin agrees with, and not impossibly borrows from, these very writers in many points of style and phraseology. The brief chapters of his work have been justly compared to the *laisses* or *tirades* of a chanson in what may be called the vignetting of the subject of each, in the absence of any attempt to run on the narrative in the precise forms, and in poetical rather than prosaic word-order of the sentences. Undoubtedly this half-poetic style (animated as it is and redeemed from any charge of bastardy by the freshness and vigor which pervade it) adds not a little to the charm of the book. Its succession of word pictures, conventional and yet vigorous as the illuminations of a mediæval manuscript, and in their very conventionality free from all thought of literary presentation, must charm all readers. The sober lists of names with which it opens; the account of the embassy, so business-like in its estimates of costs and terms, and suddenly breaking into a fervent description of how the six deputies, "prostrating themselves on the earth and weeping warm tears, begged the doge and people of Venice to have pity on Jerusalem;" the story immediately following how the young count Thibault of Champagne, raising himself from a sick-bed in his joy at the successful return of his ambassadors, "liva sus et chevaucha, et laz! com grant domages, car onques puis ne chevaucha que cele foiz," compose a most striking overture. Then the history relapses into the business vein and tells of the debates which took place as to the best means of carrying out the vow after the count's decease, the rendezvous, too ill kept at Venice, the plausible suggestions of the Venetians that the balance due to them should be made up by a joint attack on their enemy, the king of Hungary. Villehardouin does not in the least conceal the fact that the pope ("l'apostoilles de Rome," as he calls him in the very phrase of the chansons) was very angry with this; for his own part he seems to think of little or nothing but the reparation due to the republic, which had loyally kept its bargain and been defrauded of the price, of the infamy of breaking company on the part of members of a joint association, and perhaps of the unknightliness of not taking up an adventure whenever it presents itself. For here again the restoration of the disinherited prince of Constantinople supplied an excuse quite as plausible as the liquidation of the debt to Venice. A famous passage and one short enough to quote is that describing the old blind doge Dandolo, who had "Grant ochoison de remanoir (reason for staying at home), car viels hom ere, et si avoit les yaulx en la teste biaus et n'en veoit gote (goutte)," and yet was the foremost in fight.

It would be out of place to attempt any further analysis of the *Conquête* here. But it is not impertinent, and is at the same time an excuse for what has been already said, to repeat that Villehardouin's book, brief as it is, is in reality one of the capital books of literature, not merely for its merit, but because it is the most authentic and the most striking embodiment in contemporary literature of the sentiments which determined the action of a great and important period of history. There are but very few books which hold this position, and Villehardouin's is one of them. If every other contemporary record of the crusades perished, we should still be able by aid of this to understand and realize what the mental attitude of crusaders, of Teutonic knights, and the rest was, and without this we should lack the earliest, the most undoubtedly genuine, and the most characteristic of all such records. The very inconsistency with which Villehardouin is chargeable, the absence of compunction with which he relates the changing of a sacred religious pilgrimage into something by no means unlike a mere filibustering raid on the great scale, add a charm to the book. For, religious as it is, it is entirely free from the very slightest touch of hypocrisy or indeed of self-consciousness of any kind. The famous description of the crusades, *gesta Dei per Francos*, was evidently to Villehardouin a plain matter-of-fact description, and it no more occurred to him to doubt the divine favor being extended to the expeditions against Alexius or Theodore than to doubt that it was shown to expeditions against Saracens and Turks.

The person of Villehardouin reappears for us once, but once only, in the chronicle of his continuator, Henri de Valenciennes. There is a great gap in style, though none in subject, between the really poetical prose of the first historian of the fifth crusade and the Latin empire and the awkward mannerism (so awkward that it has been taken to represent a "dis-rhymed" verse chronicle) of his follower. But the much greater length at which Villehardouin appears on this one occasion shows us the restraint which he must have exercised in the passages which deal with himself in his own work. He again led the vanguard in the emperor Henry's expedition against Burilas the Bulgarian, and he is represented by the Valenciennes scribe as encouraging his sovereign to the attack in a long speech. Then he disappears altogether, with the exception of some brief and chiefly diplomatic mentions. Du Cange discovered and quoted a deed of donation by him dated 1207, by which certain properties were devised to the churches of Notre Dame de Foissy and Notre Dame de Troyes, with the reservation of life interests to his daughters Alix and Damerones, and his sisters Emmeline and Haye, all of whom appear to have embraced a monastic life. A letter addressed from the East to Blanche of Champagne is cited, and a papal record of 1212 styles him still "marshal of Romania." The next year this title passed to his son Erard; and 1213 is accordingly given as the date of his death, which, as there is no record or hint of his having returned to France, may be supposed to have happened at Messinople, where also he must have written the *Conquête.*

The book appears to have been known in the ages immediately succeeding his own; and, though there is no contemporary manuscript in existence, there are some half dozen which appear to date from the end of the 13th or the course of the 14th century, while one at least appears to be a copy made from his own work in that spirit of unintelligent faithfulness which is much more valuable to posterity than more intelligent editing. The first printed edition of the book, by a certain Blaise de Vigenère, dates from 1585, is dedicated to the seigniory of Venice (Villehardouin, it should be said, has been accused of a rather unfair predilection for the Venetians), and speaks of either a part or the whole of the memoirs as having been printed twelve years earlier. Of this earlier copy nothing seems to be known. A better edition, founded on a Netherlandish MS., appeared at Lyons in 1601. But both these were completely antiquated by the great edition of Du Cange, in 1657, wherein that learned writer employed all his knowledge, never since equalled, of the subject, but added a translation, or rather paraphrase, into modern French which is scarcely worthy either of himself or his author. Dom Brial gave a new edition from different MS. sources in 1823, and the book figures with different degrees of dependence on Du Cange and Brial in the collections of Petitot, Buchon, and Michaud and Poujoulat. All these, however, have been superseded for the modern student by the editions of M. Natalis de Wailly (1872 and 1874), in which the text is critically edited from all the available MSS. and a new translation added. The charm of Villehardouin can escape no reader; but few readers will fail to derive some additional pleasure from the two essays which Sainte-Beuve devoted to him thirty years ago, and which may be found reprinted in the ninth volume of the *Causeries du Lundi.* (G. SA.)

VILLEINAGE. See Copyhold and Slavery.

VILLEMAIN, Abel François (1790–1867), historian of French literature, was born at Paris on 11th June, 1790. He was educated at the lycée Louis-le-Grand, and was only twenty when he was appointed to an assistant-mastership at the lycée Charlemagne. This appointment was shortly exchanged for a post at the École Normale. He early devoted himself to the composition of the Academic prize essays which have founded the fortune of so many French men of letters, and in 1812 he gained the prize with an *éloge* on Montaigne, which was followed by other successful attempts. His second successful essay, *On Criticism*, had the honor of being read by the author before the Academy and the allied sovereigns who were then (April, 1814) in Paris. Under the restoration he was appointed, first, assistant professor of modern history and then professor of French eloquence at the Sorbonne. Here he began and continued for about ten years a series of literary lectures which had an extraordinary effect on his younger contemporaries. The secret indeed of Villemain's great popularity and immense influence is only to be understood by exact observation of the time at which he came. He had no very extraordinary gift of style, nor was he a very original thinker. But he had the great advantage of coming just before the Romantic movement, of having a wide and catholic love of literature, and, at the the same time, of not being an extremist. All, or almost all, the clever young men of the brilliant generation of 1830 passed under his influence; and, while he enchanted those of Romantic tendency by his constant reference to, and his frank appreciation of, the beauties of English, German, Italian, and Spanish poetry, he had not the least inclination to decry the classics—either the classics proper of Greece and Rome or the so-called classics of France. In 1819 he published a book on *Cromwell*, remarkable for a Frenchman of his day, and two years later he was elected to the Academy. The time was more favorable than any previous time had been to literary men with political inclinations, and Villemain was appointed by the restoration Government "chef de l'imprimerie et de la librairie," a post involving a kind of irregular censorship of the press, and afterwards to the office of master of requests. Like others, however, Villemain became more and more Liberal, and before the revolution of July he had been deprived of his office and had been elected deputy for Evreux. This secured his fortune under Louis Philippe's reign, and, though he did not long sit in the lower chamber, he received a peerage in 1832. He was a very important member of the council of public instruction, and was twice minister of that department, while at the same time with his elevation to the upper chamber he was made secretary of the Academy. This combination made him during the whole of the July monarchy one of the chief dispensers of literary patronage in France; and, though he never drew on himself the personal ill-will which his friend and colleague Cousin attracted, it was almost inevitable that he should displease many for every one that he gratified. Villemain's literary position had moreover been somewhat left behind by the course of events, and in politics he was something of a doctrinaire. For more than the last twenty years of his life he took no open part in public affairs, though his literary activity continued to be considerable, the books which he published being in part workings-up of his brilliant Sorbonne courses. Although he still retained a great name and an important Academic position, his later years are supposed to have been somewhat saddened by the difference of his employments and consideration, as compared with those of his middle age. Villemain, in fact, was a man who had at one time, chiefly by accident and coincidence, acquired a position to which he was not quite equal. Some reflections on him in the "Notes et Pensées" to be found in Sainte-Beuve's *Causeries du Lundi*, vol. xi., are, as is too often the case in that collection when it refers to contemporaries, harsh. But it is certain that he had little originality of thought or definiteness of literary theory, that he was rather a clever exponent of ideas which happened to be popular than a convinced reasoner, and that he had an undue admiration of success. His death took place at Paris, on 8th May, 1867.

Villemain's chief work is his *Cours de la Littérature Française*, in 6 volumes, printed soon after he ceased lecturing, and reprinted long afterwards in 1864. It is a very discursive book, containing literary judgments on all sorts of subjects, and illustrating very well the fashion in which Villemain satisfied and stimulated a generation which had just become aware that literature was not limited to the productions of the men of the *grand siècle*. Almost all his later works, which are numerous, consist of collections of Academic *éloges*, lectures, and literary and historical essays. As, however, he began with a substantive historical work so did he end with one, the posthumous *History of Gregory VII.*, on which he had been known to be engaged for many years, and the long delay of which had been the cause of not a few sarcasms. Although a book of merit, it will hardly supplant Villemain's early Academic lectures as his title to remembrance and fame—such fame as is due to a teacher who succeeds in stirring up the literary faculties of men more highly gifted than himself.

VILLENA, a town of Spain, in the province of Alicante, is situated 37 miles by rail to the northwest of that town, on the right bank of the little river Vinalapo. It has narrow winding streets and is crowned by a picturesque-looking old castle. The slopes of the surrounding hills are clothed with vines, and there are also some extensive salt lagoons. The annual fair of Villena (29th Sept.–5th Oct.), dealing in the produce of the neighborhood, is still of considerable importance. The industries (soap-making, weaving, distilling) are not extensive. The population within the municipal boundaries in 1877 was 11,424.

VILLENEUVE-SUR-LOT, a town of France, chef-lieu of an arrondissement in the department of Lot-et-Garonne, is built on both sides of the river Lot, 22 miles north of Agen by a line which branches at Penne from the Agen and Périgueux Railway. Large portions of the 13th-century ramparts, altered and surmounted by machicolations in the 15th century, still remain, and high square towers rise above the gates to the northeast and southwest. The principal arch of the bridge (13th century) has a span of 118 feet and is 59 feet in height, and was built in the reign of Louis XIII. Arcades of the 13th century surround a square. Important markets of cattle, horses, wines, and Agen plums (£120,000 [$583,200] worth exported annually) are held. Boots and shoes, sausages, tinned foods, and buttons are made, and there are marble works and large mills. The population in 1881 was 9520 (commune 14,560) and in 1886 9780 (commune 14,693). Of these 1102 were prisoners at Eysses.

Villeneuve originated in a fortress built in 1264 as a refuge for the inhabitants of Pujols, whose town had been destroyed in the Albigensian War. The English held it from 1279 to 1337, and again in the 15th century. Less than a mile from Villeneuve the former abbey of Eysses, founded about the 7th century, stands on the site of the Roman town of Excisum. It is now used as a central prison, and accommodates about 1200 prisoners. On the left bank of the Lot, 2 miles south of Villeneuve, are the 13th-century walls of Pujols.

VILLIERS, GEORGE. See BUCKINGHAM, DUKE OF.

VILLON, FRANCIS (1431–1461?), whose real surname is a matter of much dispute, so that he is also called Corbueil, Corbier, De Montçorbier, and Des Loges, though in literature Villon is the sole term used, was born in 1431, and, as it seems, certainly at Paris. The mixture of the real and the ironical in the singular poems called *Testaments*, which form his chief, if not his only certain, work, make it very unsafe to speak positively as to such details of his life as depend upon them. Yet the *Testaments*, with some extant documents, are the only trustworthy information that we have, the legends and anecdotes which are told respecting him being for the most part of the most dubious, if not the most certainly apocryphal, character. It appears that he was born of poor folks, that his father died in his youth, but that his mother was alive when her son was thirty years old. The very name Villon was stated, and that by no mean authority, the president Claude Fauchet, to be merely a common and not a proper noun, signifying "cheat" or "rascal;" but this seems to be a mistake. It is, however, certain that Villon was a person of loose life, and that he continued, long after there was any excuse for it in his years, the reckless way of living common among the wilder youth of the university of Paris. He appears to have derived his surname from a friend and benefactor named Guillaume de Villon, an ecclesiastic and a person of some property and position. The poet, either by his assistance or in some other way, became a student, and took the degree of bachelor in 1450 and that of master in 1452. Between this year and 1455 nothing positive is known of him, except that nothing was known against him.

On 4th June, 1455, the first important incident of his life that is known occurred. Being in the company of a priest named Giles and a girl named Isabeau, he met a certain Breton, a master of arts, who was also in the company of a priest, Philippe Chermoye or Sermoise or Sermaise. A scuffle ensued; daggers were drawn; and Sermaise, who is accused of having attacked Villon and drawn the first blood, not only received a dagger thrust in return, but a blow from a stone which struck him down. Sermaise died of his wounds. Villon fled, and was sentenced to banishment,—a sentence which was remitted in January, 1456, the formal pardon being extant strangely enough in two different documents, in one of which the culprit is described as "François des Loges, autrement dit Villon," in the other as "François de Montcorbier." That he is also said to have described himself to the barber-surgeon who dressed his own wounds as Michael Piton is less surprising, and hardly needs an addition to the list of his aliases. It should, however, be said that the documents relative to this affair confirm the date of his birth, by representing him as twenty-six years old or thereabouts. A year later he was again in trouble. In his first broil "la femme Isabeau" is only generally named, and it is impossible to say whether she had anything to do with the quarrel. In the second, Catherine de Vaucelles, of whom we hear not a little in the poems, is the declared cause of a scuffle in which Villon was so severely beaten that to escape ridicule he fled to Angers, where he had an uncle who was a monk. It was before leaving Paris that he composed what is now known as the *Petit Testament*, of which we shall speak presently, with the rest of his poems, and which it should be said, shows little or no such mark of profound bitterness and regret for wasted life as its in every sense greater successor the *Grand Testament*. Indeed Villon's serious troubles were only beginning, for hitherto he had been rather injured than guilty. He left Paris for Angers in the very early spring of 1456–1457, and shortly afterwards (in March) the chapel of the College of Navarre was broken open and five hundred gold crowns [$607.50] stolen. The inquiries set on foot discovered a gang of student robbers, one of whom, Guy Tabarie, turned king's evidence and accused Villon, who was then absent, of being the ringleader, and of having gone to Angers, partly at least, to arrange for similar burglaries there. Other crimes were confessed by the accomplice, and Villon was arrested, put to the torture, and condemned to be hanged,—a penalty which was actually inflicted later on two of his gang, and which he commemorated by anticipation in one of the most famous and remarkable of his poems, the sombre "Ballade des Pendus." He escaped Montfaucon, however, by appealing from the bishop's court, where as a clerk he had been tried, to the parlement of Paris, by which body his sentence was commuted to banishment—that is, of course, banishment from the capital. Where he went and what he did for the next four years we do not know. It is certain that at one time, and probably that at more times than one, he was in correspondence with Charles d'Orléans, and it is likely that he resided, at any rate for some period, at that prince's court at Blois. He had also something to do with another prince of the blood, Jean of Bourbon, and traces are found of him in Poitou, in Dauphiné, etc. But at his next certain appearance he is again in trouble. He tells us that he had spent the summer of 1461 in the bishop's prison (bishops were fatal to Villon) of Meung. His crime is not known; but his enemy, or at least judge, was Thibault d'Aussigny, who held the see of Orleans. Villon owed his release to a general jail delivery at the accession of Louis XI., and became a free man again on 2d October.

It was now that he wrote the *Grand Testament*, and this, the work which has immortalized him, is the last certain fact which is known of his life. If one could judge from a vague kind of internal evidence, it would seem likely that it is really a testament, and that the poet died soon afterwards. Although he was only thirty at the date of this composition (which is unmistakable, because given in the book itself), there seems to be no kind of aspiration towards a new life, nor even any hankering after the old. Nothing appears to be left him but regret; his very spirit has been worn out by excesses or sufferings or both. But, however this may be, he disappears from history. Rabelais indeed tells two stories about him which have almost necessarily been dated later. One is a countryside anecdote of a trick supposed to have been played by the poet in his old age at Saint Maixent in Poitou, whither he had retired. The other, a coarse but pointed jest at the expense of England, is told as having been addressed by Villon to King Edward V. during an exile in that country. Now even if King Edward V. were not evidently out of the question, a passage of the story refers to the well-known scholar and man of science, Thomas Linacre, as court physician to the king, and makes Villon mention him, whereas Linacre was only a young scholar, not merely at the time of Edward V.'s supposed murder, but at the extreme date (1489) which can be assigned to Villon's life. For in this year the first edition of the poet's work appeared, obviously not published by himself, and with no sign in it of his having lived later than the date (1461) of the *Grand Testament*. It would be easy to dismiss these Rabelaisian mentions of Villon as mere humorous inventions, if it were not that the author of *Pantagruel* was born quite soon enough to have actually seen Villon if he had lived to anything that could be called old age, that he almost certainly must have known men who had known Villon, and that the poet undoubtedly spent much time in Rabelais's own country on the banks of the lower Loire.

The obscurity, the unhappiness, and the evil repute of Villon's life would not be in themselves a reason for the minute investigation to which the events of that life have been subjected, and the result of which has been summed up here. But his poetical work, scanty as the certainly genuine part of it is, is of such extraordinary interest, and marks such an epoch in the history of European literature, that he has been at all times an interesting figure, and, like all very interesting figures, has been often praised for qualities quite other than those which he really possessed. Boileau's famous verses, in which Villon is extolled for having first known how to smooth out the confused art of the old romancers, are indeed a prodigy of blundering or ignorance or both. As far as art, or the technical part of poetry goes, Villon made not the slightest advance on his predecessors, nor stood in any way in front of such contemporaries as his patron Charles d'Orléans. His two *Testaments* (so called by the application to them of a regular class-name of mediæval poetry) consist of eight-line stanzas of eight-syllabled verses, varied in the case of the *Grand Testament* by the insertion of ballades and rondeaux of very great beauty and interest, but not formally different in any way from poems of the same kind for more than a century past. What really distinguishes Villon is the intenser quality of his poetical feeling and expression, and what is perhaps arrogantly called the modern character of his subjects and thought. Mediæval poetry, with rare exceptions, and, with exceptions not quite so rare, classical poetry, are distinguished by their lack of what is now called the personal note. In Villon this note sounds, struck with singular force and skill. Again, the simple joy of living which distinguishes both periods—the mediæval, despite a common opinion, scarcely less than the ancient—has disappeared. Even the riot and rollicking of his earlier days are mentioned with far less relish of remembrance than sense of their vanity. This sense of vanity, indeed, not of the merely religious, but of the purely mundane and even half pagan kind, is Villon's most prominent characteristic. It tinges his narrative, despite its burlesque bequests, all through; it is the very keynote of his most famous and beautiful piece, the "Ballade des Dames du Temps Jadis." with its refrain "Mais où sont les neiges d'antan?" as well as of his most daring piece of realism, the other ballade of "La Grosse Margot," with its burden of hopeless entanglement in shameless vice. It is nowhere more clearly sounded than in the piece which ranks with these two at the head of his work, the "Regrets de la Belle Heaulmière," in which a woman, once young and beautiful, now old and withered, laments her lost charms. So it is almost throughout his poems, including the grim "Ballade des Pendus," and hardly excluding the very beautiful "Ballade pour sa Mère," with its description of sincere and humble piety. It is in the profound melancholy which the dominance of this note has thrown over Villon's work, and in the suitableness of that melancholy to the temper of all generations since, that his charm and power have consisted, though it is difficult to conceive any time at which his poetical merit could be ignored.

His certainly genuine poems consist of the two *Testaments* with their codicil (the latter containing the "Ballade des Pendus," or more properly "Epitaphe en Forme de Ballade," and some other pieces of a similarly grim humor), a few miscellaneous poems, chiefly ballades, and an extraordinary collection (called *Le Jargon*) of poems in *argot*, the greater part of which is now totally unintelligible, if, which may perhaps be doubted, it ever was otherwise. Besides these, certain poems of no inconsiderable interest are usually printed with Villon's works, though they are certainly, or almost certainly, not his. The chief are "Les Repues Franches," a curious series of verse stories of cheating tavern-keepers, etc., having some resemblance to those told of George Peele, but of a broader and coarser humor. These are beyond doubt, if not the poet's work, nearly contemporary with him, and may have some foundation in fact. Another of these spurious pieces is the extremely amusing monologue of the "Franc Archier de Bagnolet," in which one of the newly constituted archers or regularly trained and paid soldiery, who were extremely unpopular in France, is made to expose his own poltroonery. The third most important piece of this kind is the "Dialogue de Mallepaye et de Baillevent," a dramatic conversation between two penniless spendthrifts, which is not without merit. These poems, however, were never attributed to Villon or printed with his works till far into the 16th century.

It has been said that the first dated edition of Villon is of 1489, though some have held one or more than one undated copy to be still earlier. Between the first, whenever it was, and 1542 there were no less than twenty-seven editions, the most famous being that of Clément Marot in 1533, one of whose most honorable distinctions is the care he took of his poetical predecessors. The Pléiade movement and the classicizing of the *grand siècle* put Villon rather out of favor, and he was not again reprinted till early in the 18th century, when he attracted the attention of students of old French like Duchat, La Monnoye, and Prosper Marchand. The first critical edition in the modern sense—that is to say, an edition founded on MSS. (of which there are in Villon's case several, chiefly at Paris and Stockholm)—was that of the Abbé Prompsault in 1832. The next and on the whole the most important was that of the bibliophile Jacob (P. Lacroix) in the Bibliothèque Elzevirienne (Paris, 1854). Since then Villon has been frequently reprinted, very great interest having been shown in him; but not much has been done to the text till the recent and uncompleted labors of a Dutch scholar, Dr. Bijvanck, who is occupied especially on the Stockholm MSS. On the other hand, from the literary and biographical view, Villon has been exhaustively studied of late, especially by MM. Campaux, Vitu, and Longnon, the researches of the last-named (Paris, 1877) having probably ascertained everything that there is to know. In England, too, attempts have been made to translate his work, especially by the late D. G. Rossetti, by Mr. Swinburne, and by Mr. Andrew Lang, while a complete translation has been produced by Mr. John Payne. (G. SA.)

VILNA, or **WILNO**, a Lithuanian government of west Russia, has the Polish province of Suwałki on the W., Kovno and Vitebsk on the N. and E., and Minsk and Grodno on the E. and S. Its area is 16,421 square miles. Vilna lies on the broad marshy swelling, dotted with lakes, which separates POLAND (*q.v.*) from East Prussia and stretches east-northeast towards the Valdai Plateau. Its highest parts are a little more than 1000 feet above sea-level. On its western and eastern boundaries Vilna is deeply trenched by the valleys of the Niemen and the Dwina. Devonian limestones crop out in the northeast. Elsewhere they are concealed by the marine and fresh-water limestones and sandstones of the Eocene period, which cover nearly the whole of Vilna; and these in their turn are overlain by thick layers of boulder clay, sands, and lacustrine deposits. The soil is for the most part clayey or sandy, fertile loam appearing only in the depression watered by the Vilia. Numerous lakes and marshes, partly covered with forests, and scarcely passable except when frozen, as well as wet meadow-land, occupy a large area in the central parts of Vilna. The Niemen, which flows along the southern and western borders for more than 200 miles, is the chief artery of trade for the government, and its importance in this respect is enhanced by its tributary the Vilia, which flows west for more than 200 miles through the central parts of Vilna, receiving many affluents on its course. Among the tributaries of the Niemen is the Berezina, which acquired renown during Napoleon's retreat in 1812; it flows in a marshy valley in the southeast. The Dwina for 50 miles of its course separates Vilna from Vitebsk. The combined traffic on the Niemen and the Dwina was valued at nearly £200,000 [$972,000] in 1883. The climate of the government is only slightly tempered by its proximity to the Baltic Sea (January 21.8° Fahr.; July 64.5°); the average temperature at the town of Vilna is only 43.5.° But in winter the thermometer descends very low, the minimum observed during the last sixty years being — 30°. The flora and fauna are intermediate between those of Poland and middle Russia. The population of Vilna, which amounted to 1,223,260 in 1883, consists chiefly of Lithuanians (35 per cent.) in the west and north and White Russians (45 per cent.) in the south and east. Jews make up 11 per cent. of the population; and the Poles, who constitute the landed aristocracy and the artisan classes of the towns, reach 7 per cent. A few Great Russians and Tatars, descendants of Crimean prisoners, must be added to the above. Roman Catholicism is the prevailing creed among the Lithuanians and Poles; and the White Russians belong for the most part to the Greek and Nonconformist Churches.

In spite of the unfertile soil, sufficient cereals are grown for the needs of the population and to supply the distilleries. The average crops of 1882–1885 were 1,010,000 quarters of rye, 44,000 of wheat, 790,000 of various kinds of grain, and 9,840,000 bushels of potatoes. Apart from finer breeds kept by a few landowners, the cattle of the peasantry belong to inferior varieties. In 1883 there were 203,620 horses, 303,100 horned cattle, 277,800 sheep, and 238,800 pigs. More than one-third of the area is covered with forests, whence a considerable quantity of timber is exported, partly to Germany, for shipbuilding. A variety of petty trades are carried on in the villages of the forest region—sledges, cars, wheels, and wooden ware being made by the peasants. Tar, pitch, and potash are exported. The manufactures have only begun to develop of late. In 1884 there were 300 establishments employing 3020 men, and giving an annual output valued at £885,100 [$4,301,586] (as against £200,000 [$972,000] in 1860). An active trade in timber, corn, and flax (exported) and in manufactured goods (imported) is carried on. Vilna is divided into seven districts, the chief towns of which (with their populations in 1883) are—Vilna (see below), Vileika (3905), Disna (8030), Lidy or Lida (7940), Oshmiany (4470), Svienciany (8510), and Troki (2440).

VILNA, or **WILNO**, capital of the above government, is situated 436 miles to the southwest of St. Petersburg, at the junction of the Vilia with the Vileika, and at the intersection of two great railway lines, one from St. Petersburg to Warsaw, the other from Libau to the mouth of the Don. It is an old town, rich in historical associations. Its imperial palace, and the cathedral of St. Stanislaus, containing the silver sarcophagus of St. Casimir, are fine buildings. The (Greek) cathedral of the Holy Virgin contains the remains of Prince Olgerd (baptized in 1377) and his family. The museum of antiquities has valuable historical collections of the region. The ancient castle of the Jagellones is now a mass of ruins. The old university, founded in 1576, was restored by Alexander I., but has been closed since 1832 for political reasons; the only departments which remain in activity are the astronomical observatory and a medical academy. The scientific societies of Vilna, especially the medical and archæological, are well known. In spite of the war of 1812, and the Polish risings of 1831 and 1863, the population has of late increased rapidly. In 1883 it numbered 93,760. The inhabitants are chiefly Roman Catholics in religion and Poles by nationality. The Jews are steadily increasing in numbers and now make more than one-third of the population. The town has an important trade in timber (with Prussia), as also in corn.

History.—The territory of Vilna has certainly been occupied by the Lithuanians since the 10th century, and probably much earlier; their chief fortified town, Vilna, is first mentioned in 1128. A temple to the god Perkunas stood on one of its hills till 1387, when it was destroyed by Jagello, after his baptism. After 1323, when Gedimin abandoned Troki, Vilna became the capital of Lithuania. The formerly independent principalities of Minsk and Lidy, as well as the territory of Disna, which belonged to the Polotsk principality, were annexed by the Lithuanian princes, and from that time Vilna, which was fortified by a stone wall, became the chief city of the Lithuanian empire. It was united with Poland when its prince Casimir was elected (1444) to the Polish throne. In 1519 it had a printing-office, and fifty years later the Jesuits founded there a college, which became later on a university. But the plague of 1588, a fire in 1610, and still more the wars between Russia and Poland, which began in the 17th century, checked its further growth. The Russians took Vilna in 1655, and in the following year it was ceded to Russia. The Swedes captured it in 1702 and in 1706. The Russians again took possession of it in 1788; and it was finally annexed to Russia in 1795, after the partition of Poland. Its Polish inhabitants took an active part in the risings of 1831 and 1863, for which they were severely punished by the Russian Government.

VINCENNES, a town of France, in the department of Seine, 4 miles east of Paris, with which it is connected by a railway and two tramways. The castle, formerly a royal residence, was begun by Louis VII. in 1164, and rebuilt by Philip Augustus, Philip of Valois, and Charles V. Catherine de' Medici added two pavilions, finished in 1614, which Louis XIV. connected by two covered galleries, one of which has been destroyed and the other hidden by casemates. Napoleon altered the castle into a vast magazine of war materials. Louis XVIII. added an armory; and under Louis Philippe numerous casemates and a new fort on the east side were constructed. The population of Vincennes, 20,530 in 1881, was 22,237 in 1886.

The old castle is a rectangle of 1253 feet by 735. The enclosing wall was originally flanked by nine towers, which were cut down to its level between 1808 and 1811, and now serve as bastions. Vincennes is at once a barracks, a fortress, an arsenal, and a school of artillery, and is the scene of most new artillery experiments in France. The donjon is a square tower 170 feet high, with walls 10 feet thick. The chapel, begun by Charles V. in 1379, continued by Charles VI. and Francis I., and finished by Henry II. in 1552, has been recently restored. In the sacristy is the monument erected in 1816 to the memory of the duke of Enghien, who was shot in the castle moat in 1804. Vincennes possesses a military hospital with 642 beds, and a statue of General Daumesnil, erected in 1873. The wood of Vincennes contains various military establishments, an experimental farm, and the redoubts of Gravelle and La Faisanderie. In the latter is the normal school of military gymnastics. The wood, which now belongs to Paris, was laid out during the second empire in imitation of the Bois de Boulogne. In the Lake of Gravelle the waters of the Marne are collected in a reservoir, holding upwards of 700,000 cubic feet. The Marne flows 130 feet below. On the south border of the wood near Charenton is the asylum of Vincennes (500 beds), founded in 1855 for the benefit of convalescents from the hospital.

VINCENNES, a city of the United States, the county seat of Knox county, Indiana, is situated on the east bank of the Wabash, which is navigable to this point. It is the centre of a fertile agricultural district, with extensive underlying coal deposits, and is an important railroad centre, where seven railroads intersect. These railroads have their workshops here, in which they employ a large number of men. Besides this there are flour mills, a woollen mill, furniture and segar factories, and machine shops. The population in 1880 was 7680, an increase since 1870 of 42 per cent. Vincennes is the seat of a university,[1] chartered in 1804.

The site of the city was settled in 1702. In 1763 the British became its possessors, and it remained a British fort until captured by Colonel G. R. Clarke, in 1779. From 1800 to 1813 it was the capital of Indiana Territory.

VINCENT, or VINCENTIUS, ST., deacon and martyr, according to the Roman *Breviary*, was born of noble parents at Huesca (Osca) in Spain, and was educated by Valerius, bishop of Zaragoza, who in due time ordained him to the diaconate. Under the persecution of Diocletian he was arrested and taken to Valencia. Having stood firm in his profession before Dacianus, the governer, he was subjected to excruciating tortures and thrown into prison, where angels visited him, lighting up his dungeon with celestial light, relieving his pains, loosing his bonds, and mingling their voices with his in psalms of praise. His warders, having seen these wonders through the chinks of the wall, forthwith became Christians. He was afterwards brought out and laid upon a soft mattress that he might regain sufficient strength for new torments; but while Dacianus was vainly meditating punishment, the saint gently breathed his last, as a crowd of bystanders kissed his feet and treasured up his blood in napkins. The tyrant exposed the body to wild beasts, but a raven miraculously descended and protected it; it was then thrown into the sea, but could not be hid, and finally received decent burial. The date assigned to his martyrdom is 304; he is commemorated on 22d January, chiefly in Spain and the patriarchate of Lisbon. Prudentius (403) devotes a hymn to the details of his martyrdom; Paulinus calls him the glory and ornament of Spain; and in more than one of his discourses St. Augustine has celebrated his praise.

VINCENT, GEORGE (1796–1831?), English landscape and marine painter, was born at Norwich in June, 1796. He studied art under "Old" Crome, and at the age of fifteen began to contribute to the Norwich exhibition. From 1814 till 1823 he exhibited occasionally at the Royal Academy, and also in the Water-Color Exhibition and the British Institution. In 1819 he removed from Norwich to London, and he was a contributor to the Suffolk Street gallery from its foundation in 1824 till 1830. He possessed great artistic abilities; but unfortunately he fell into dissipation, and his works became slight and hastily executed. Finally he dropped out of sight, and he is believed to have died about 1831. His most important work, a view of Greenwich Hospital, was shown in the International Exhibition of 1862. His London from the Surrey Side of Waterloo Bridge is also a fine work.

VINCENT OF BEAUVAIS, or VINCENTIUS BELLOVACENSIS (*c.* 1190–*c.* 1264), the encyclopædist of the Middle Ages, was probably a native of Beauvais.[2] The exact dates of his birth and death are unknown. A tolerably old tradition, preserved by Louis a Valleoleti (*c.* 1413), gives the latter as 1264;[3] but Tholomæus de Luca, Vincent's younger contemporary (*ob.* 1321), seems to reckon him as living during the pontificate of Gregory X. (1272–1276). If we assume 1264 as the year of his death, the immense volume of his works forbids us to think he could have been born much later than 1190. Very little is known of his career. A plausible conjecture makes him enter the house of the Dominicans at Paris between 1215 and

---

[1] [Rather of a preparatory academy.—AM. ED.]

[2] He is sometimes styled Vincentius Burgundus; but, according to M. Daunou, this appellation cannot be traced back further than the first half of the 15th century.

[3] Apparently confirmed by the few enigmatical lines preserved by Echard from his epitaph—

> "Pertulit iste necem post annos mille ducentos,
> Sexaginta decem sex habe, sex mihi retentos."

1220, from which place a second conjecture carries him to the Dominican monastery founded at Beauvais in 1228–29. There is no evidence to show that the Vincent who was sub-prior of this foundation in 1246 is the encyclopædist; nor indeed is it likely that a man of such abnormally studious habits could have found time to attend to the daily business routine of a monastic establishment. It is certain, however, that he at one time held the post of "reader" at the monastery of Royaumont (*Mons Regalis*), not far from Paris on the Oise, founded by St. Louis between 1228 and 1235. St. Louis read the books that he compiled, and supplied the funds for procuring copies of such authors as he required for his compilations. Queen Margaret, her son Philip, and her son-in-law Theobald V. of Champagne and Navarre are also named among those who urged him to the composition of his "little works," especially the *De Institutione Principum.* Though Vincent may well have been summoned to Royaumont even before 1240, there is no actual proof that he lived there before the return of Louis IX. and his wife from the Holy Land, early in the summer of 1254. But it is evident that he must have written his work *De Eruditione Filiorum Regalium* (where he styles himself as "Vincentius Belvacensis, de ordine prædicatorum, qualiscumque lector in monasterio de Regali Monte") after this date and yet before January, 1260, the approximate date of his *Tractatus Consolatorius.* When he wrote the latter work he must have left Royaumont, as he speaks of returning from the funeral of Prince Louis (15th January, 1260) "ad nostram domum," a phrase which can hardly be explained otherwise than as referring to his own Dominican house, whether at Beauvais or elsewhere.

The *Majus Speculum*, the great compendium of all the knowledge of the Middle Ages, as it left the pen of Vincent, seems to have consisted of three parts only, viz., the *Speculum Naturale, Doctrinale*, and *Historiale.* Such, at least, is Échard's conclusion, derived from an examination of the earliest extant MSS. All the printed editions, however, consist of four parts, the additional one being entitled *Speculum Morale.* This has been clearly shown to be the production of a later hand, and is ascribed by Échard to the period between 1310 and 1325. In arrangement and style it is quite different from the other three parts, and indeed it is mainly a compilation from Thomas Aquinas, Stephen de Bourbon, and two or three other contemporary writers.

The *Speculum Naturale* fills a bulky folio volume of 848 closely-printed double-columned pages. It is divided into thirty-two books and 3718 chapters. It is a vast summary of all the natural history known to western Europe towards the middle of the 13th century. It is, as it were, the great temple of mediæval science, whose floor and walls are inlaid with an enormous mosaic of skilfully arranged passages from Latin, Greek, Arabic, and even Hebrew authors. To each quotation, as he borrows it, Vincent prefixes the name of the book and author from whom it is taken, distinguishing, however, his own remarks by the word "actor." The *Speculum Naturale* is so constructed that the various subjects are dealt with according to the order of their creation; it is in fact a gigantic commentary on Genesis i. Thus bk. i. opens with an account of the Trinity and its relation to creation; then follows a similar series of chapters about angels, their attributes, powers, orders, etc., down to such minute points as their methods of communicating thought, on which matter the author decides, in his own person, that they have a kind of intelligible speech and that with angels to think and to speak are not the same process. The whole book, in fact, deals with such things as were with God "in the beginning." Bk. ii. treats of our own world, of light, color, the four elements, Lucifer, and his fallen angels, thus corresponding in the main with the sensible world and the work of the first day. Bks. iii. and iv. deal with the phenomena of the heavens and of time, which is measured by the motions of the heavenly bodies, with the sky and all its wonders, fire, rain, thunder, dew, winds, etc. Bks. v.–xiv. treat of the sea and the dry land: they discourse of the seas, the ocean, and the great rivers, agricultural operations, metals, precious stones, plants, herbs, with their seeds, grains, and juices, trees, wild and cultivated, their fruits and their saps. Under each species, where possible, Vincent gives a chapter on its use in medicine, and he adopts for the most part an alphabetical arrangement. In bk. vi. c. 7 he incidentally discusses what would become of a stone if it were dropped down a hole, pierced right through the earth, and curiously enough, decides that it would stay in the centre. Bk. xv. deals with astronomy—the moon, stars, and the zodiac, the sun, the planets, the seasons, and the calendar. Bks. xvi. and xvii. treat of fowls and fishes, mainly in alphabetical order and with reference to their medical qualities. Bks. xviii.–xxii. deal in a similar way with domesticated and wild animals, including the dog, serpents, bees, and insects; they also include a general treatise on animal physiology spread over bks. xxi.–xxii. Bks. xxiii.–xxviii. discuss the psychology, physiology, and anatomy of man, the five senses and their organs, sleep, dreams, ecstacy, memory, reason, etc. The remaining four books seem more or less supplementary; the last (xxxii.) is a summary of geography and history down to the year 1250, when the book seems to have been given to the world, perhaps along with the *Speculum Historiale* and possibly an earlier form of the *Speculum Doctrinale.*

The *Speculum Doctrinale*, in seventeen books and 2374 chapters, is a summary of all the scholastic knowledge of the age and does not confine itself to natural history. It is intended to be a practical manual for the student and the official alike; and to fulfil this object, it treats of the mechanic arts of life as well as the subtleties of the scholar, the duties of the prince, and the tactics of the general. The first book, after defining philosophy, etc., gives a long Latin vocabulary of some 6000 or 7000 words. Grammar, logic, rhetoric, and poetry are discussed in bks. ii. and iii., the latter including several well-known fables, such as the Lion and the Mouse. Bk. iv. treats of the virtues, each of which has two chapters of quotations allotted to it, one in prose and the other in verse. Bk. v. is of a somewhat similar nature. With bk. vi. we enter on the practical part of the work; it deals with the *ars œconomica*, and gives directions for building, gardening, sowing, reaping, rearing cattle, and tending vineyards; it includes also a kind of agricultural almanac for each month in the year. Bks. vii.–ix. have reference to the *ars politica:* they contain rules for the education of a prince and a summary of the forms, terms, and statutes of canonical, civil, and criminal law. Bk. xi. is devoted to the *artes mechanicæ*, namely, those of weavers, smiths, armorers, merchants, hunters, and even the general and the sailor. Bks. xii.–xiv. deal with medicine both in practice and in theory: they contain practical rules for the preservation of health according to the four seasons of the year, and treat of various diseases from fever to gout. Bk. xv. deals with physics and may be regarded as a summary of the *Speculum Naturale.* Bk. xvi. is given up to mathematics, under which head are included music, geometry, astronomy, astrology, weights and measures, and metaphysics. It is noteworthy that in this book Vincent shows a knowledge of the Arabic numerals, though he does not call them by this name. With him the unit is termed "digitus"; when mutiplied by ten it becomes the "articulus"; while the combination of the articulus and the digitus is the "numerus compositus." In this chapter (xvi. 9), which is superscribed "actor," he clearly explains how the value of a number increases tenfold with every place it is moved to the left. He is even acquainted with the later invention of the "cifra" or cipher. The last book (xvi.) treats of theology or (as we should now say) mythology, and winds up with an account of the Holy Scriptures and of the fathers, from Ignatius and Dionysius the Areopagite to Jerome and Gregory the Great, and even of later writers from Isidore and Bede, through Alcuin, Lanfranc, and Anselm, down to Bernard of Clairvaux and the brethren of St. Victor.

As the fifteenth book of the *Speculum Doctrinale* is a summary of the *Speculum Naturale*, so the *Speculum Historiale* may be regarded as the expansion of the last book of the same work. It consists of thirty-one books divided into 3793 chapters. The first book opens with the mysteries of God and the angels, and then passes on to the works of the six days and the creation of man. It includes dissertations on the various vices and virtues, the different arts and sciences, and carries down the history of the world to the sojourn in Egypt. The next eleven books (ii.–xii.) conduct us through sacred and secular history down to the triumph of Christianity under Constantine. The story of Barlaam and Josaphat occupies a great part of bk. xv.; and bk. xvi. gives an account of Daniel's nine kingdoms, in which account Vincent differs from his professed authority, Sigebert of Gembloux, by reckoning England as the fourth instead of the fifth. In the chapters devoted to the *origines* of Britain he relies on the Brutus legend, but cannot carry his catalogue of British or English kings further than 735, where he honestly confesses that his authorities fail him. Seven more books bring us to the rise of Mohammed (xxiii.) and the days of Charlemagne (xxiv.). Vincent's Charlemagne is a curious medley of the great emperor of history and the champion of romance. He is at once the gigantic eater of Turpin, the huge warrior eight feet high, who could lift the armed knight standing on his open hand to a level with his head, the crusading conqueror of Jerusalem in days before the crusades, and yet with all this the temperate drinker and admirer of St. Augustine, as his character had filtered down through various channels from the historical pages of Eginhard. Bk. xxv. includes the first crusade, and in the course of bk. xxix., which contains an account of the Tartars, the author enters on what is almost contemporary history, winding up in bk. xxxi. with a short narrative of the crusade of St. Louis in 1250. One remarkable feature of the *Speculum Historiale* is Vincent's constant habit of devoting several chapters to selections from the writings of each great author, whether secular or profane, as he mentions him in the course of his work. The extracts from Cicero and Ovid, Origen and St. John, Chrysostom, Augustine, and Jerome, are but specimens of a useful custom which reaches its culminating point in bk. xxviii., which is devoted entirely to the writings of St. Bernard. One main fault of the *Speculum Historiale* is the unduly large space devoted to miracles. Four of the mediæval historians from whom he quotes most frequently are Sigebert of Gembloux, Hugh of Fleury, Helinand of Froidmont, and William of Malmesbury, whom he uses for Continental as well as for English history.

Vincent has thus hardly any claim to be reckoned as an original writer. But it is difficult to speak too highly of his immense industry in collecting, classifying and arranging these three huge volumes of 80 books and 9885 chapters. The undertaking to combine all human knowledge into a single whole was in itself a colossal one and could only have been born in a mind of no mean order. Indeed more than six centuries passed before the idea was again resuscitated; and even then it required a group of brilliant Frenchmen to do what the old Dominican had carried out unaided. The number of writers quoted by Vincent is almost incredible: in the *Speculum Naturale* alone no less than 350 distinct works are cited, and to these must be added at least 100 more for the other two *Specula*. His reading ranges from Arabian philosophers and naturalists to Aristotle, Eusebius, Cicero, Seneca, Julius Cæsar (whom he calls Julius Celsus), and even the Jew Peter Alphonso. But Hebrew, Arabic, and Greek he seems to have known solely through one or other of the popular Latin versions.

A list of Vincent's works, both MS. and printed, will be found in the *Histoire Littéraire de France*, vol. xviii., and in Échard. The *Tractatus Consolatorious pro Morte Amici* and the *Liber de Eruditione Filiorum Regalium* (dedicated to Queen Margaret) were printed by Amerbach at Basel in December, 1480. The *Liber de Institutione Principum* has never yet been printed, and the only MS. copy the writer of this article has been able to consult does not contain in its prologue all the information which Échard seems to imply is to be found there. The so-called first edition of the *Speculum Majus*, including the *Speculum Morale*, ascribed to Mentelin and long celebrated as the earliest work printed at Strasburg, has lately been challenged as being only an earlier edition of Vincent's three genuine *Specula* (*c.* 1468–70), with which has been bound up the *Speculum Morale* first printed by Mentelin (*c.* 1473–76). (T. A. A.)

VINCENT OF LERINS, ST., an ecclesiastical writer of the Western Church, of whose personal history hardly anything is known, except that he was a native of Gaul, possibly brother of St. Loup, bishop of Troyes, that he became a monk and priest in the monastery of Lerinum (island of St. Honorat, opposite Cannes), and that he died in or about 450. From himself we further learn that only after long and sad experience of worldly turmoil did he betake himself to the haven of a religious life. In 434, three years after the council of Ephesus, he wrote the *Commonitorium adversus profanas omnium hæreticorum novitates*, in which the famous threefold test of orthodoxy is laid down and applied,—"quod ubique, quod semper, quod ab omnibus creditum est." It is not altogether improbable that Vincent of Lerins was also the author of the Semipelagian treatise against Augustinianism which is dealt with by Prosper of Aquitania in his *Pro Augustini doctrina responsiones ad capitula objectionum Vincentianarum.*

The *Commonitorium* has been edited by Baluze (Paris, 1663, 1669, and 1684), and by Klüpfel (Vienna, 1809). It also occurs in vol. l. of Migne's *Patrol. curs. compl.* (1846).

VINCENT DE PAUL, ST. (1576–1660), founder of the "Congregation of Priests of the Mission," usually known as LAZARITES (*q.v.*), was born on 24th April, 1576, at Pouy near Dax (Landes), where his father owned a small farm. It was originally intended to train him for the ordinary pastoral life of the peasants of the Landes, but he soon showed other aptitudes, and after passing through the school at Dax he studied at Toulouse, and was ordained to the priesthood in 1600. Some time afterwards, while on board a felucca off Marseilles, he had the misfortune to be captured by Barbary pirates, who took him to Tunis and sold him as a slave. His third master, who happened to be a renegade Italian, he succeeded in converting, and both managed to make their escape, landing at Aigues-Mortes, near Marseilles, in June, 1607. After short stays at Avignon and Rome, Vincent found his way to Paris, where he became favorably known to Monsieur (afterwards cardinal) de Bérulle, who was then engaged in founding the congregation of the French Oratory. At Bérulle's instance he became curate of Clichy, near Paris (1611); but this charge he soon exchanged for the post of tutor to the count of Joigny at Folleville, in the diocese of Amiens, where he first developed the idea of those "missions" with which his name is associated. In 1617 he accepted the curacy of Châtillon-lès-Dombes (or sur-Chalaronne), and it was here that he received from the countess of Joigny the means by which he was enabled to found his first "confrérie." The subsequent history of the priests of the mission will be found in the article LAZARITES. Among the works of benevolence with which his name is more immediately and personally associated are the establishment of a hospital for galley slaves at Marseilles, the institution of two establishments for foundlings at Paris, and the organization of the "Filles de la Charité." He died at Paris on 27th September, 1660, and was buried in the church of St. Lazare. He was beatified by Benedict XIII. in 1729 and canonized by Clement XII. in 1737, his festival (duplex) being observed on 19th July.

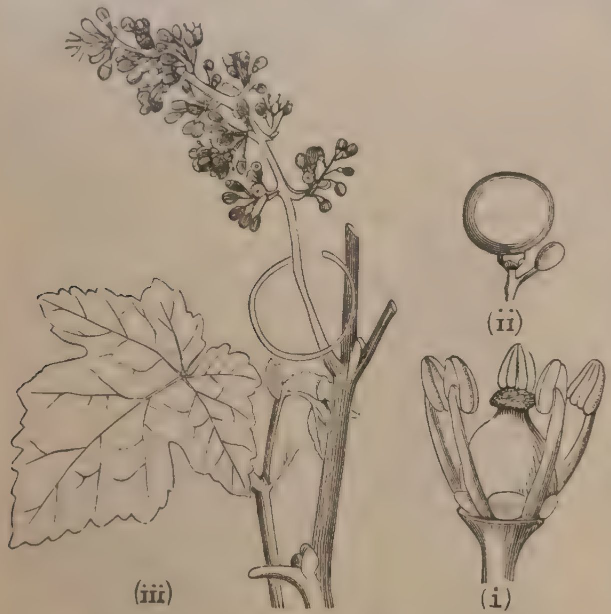
VINCENT FERRER, ST. (1355–1419), a great Spanish Dominican preacher, was born of respectable parentage at Valencia on 23d January, 1355. In February, 1374, he took the Dominican habit, and after spending some years in teaching, and in completing his theological studies, he was licensed to preach. He graduated as doctor of theology at Lerida in 1374, and his sermons in the cathedral of Valencia from 1385 onwards soon became famous. Cardinal Peter de Luna took him with him to Paris in 1391; and on his own election to the pontificate as anti-pope Benedict XIII. made Ferrer his confessor and master of the sacred palace. Finding, however, the ecclesiastical atmosphere of Avignon an uncongenial one, he in 1397 resumed his work as a preacher, and Spain, France, Italy, Germany, and Great Britain and Ireland were successively visited by him; and in every case numerous conversions were the result of his eloquence, which is described as having been singularly powerful and moving. In 1412 he was delegated by his native city to take part in the election of a successor to the vacant crown of Aragon; and in 1416 he received a special invitation to attend the council of Constance, which, however, he does not appear to have accepted. He died at Vannes on 5th April, 1419, and was canonized by Calixtus III. in 1455, his festival (duplex) being observed on 5th April.

VINCI. See LEONARDO DA VINCI.

VINDELICIA, or the country of the Vindelici, is a name of the Roman province which was also called Rhætia Secunda. See RHÆTIA.

VINE. Of the grape vines (*Vitis*) *V. vinifera* is the species best known and longest cultivated; but out of ten species that grow wild in the United States four (*V. rotundifolia*, *V. Labrusca*, *V. æstivalis*, and *V. cordifolia*), according to Engelmann, are cultivated and have given origin to numerous derivatives used for wine-making purposes. Some of the American varieties have been introduced into France and other countries infested with *Phylloxera*, to serve as stocks on which to graft the better kinds of European vines, because their roots, though perhaps equally subject to the attacks of the insects, do not suffer so much injury from them as the European species. American vines should not, however, be introduced for grafting or other purposes into a vine-growing country hitherto free from *Phylloxera*, but only into those in which the insect has already spread.

Although the genus *Vitis* comprises, according to Bentham and Hooker, more than two hundred species, mostly natives of tropical or subtropical regions, yet less than half-a-dozen species have any economic value, while the great interest centres in four or five only. Vines have woody climbing stems, with alternate, palmately-lobed, or in some cases (*Ampelopsis*, *Cissus*) compound (digitate), leaves, provided at the base with small stipules. Opposite some of these leaves springs a tendril, the nature of which is obvious from the numerous transitional states it offers between the ordinary form of tendril and the inflorescence. The flowers are small, green, and fragrant, and are arranged in dense clusters. Each has a small calyx in the form of a shallow rim, sometimes four-lobed or five-lobed, or toothed. Within this is an equal number of petals, which in the true vines cohere by their tips and form a cap or hood, which is pushed off when the stamens are ripe. In other species (and as a malformation in the vine itself) the petals are free and spreading. Four or five free stamens, placed opposite the petals, spring from a fleshy ring or disk surrounding the ovary, each bearing a two-celled anther. The ovary is surmounted by a sessile stigma and is more or less completely two-celled, with two erect ovules in each cell. This ripens into the berry and seed. Planchon, in his monograph of the *Ampelideæ* (1887), divides the genus *Vitis* into numerous genera of equal rank. He retains, however, the grape vines under their original name. The cultivated vine has usually hermaphrodite flowers; but, as it occurs in a wild state, or as an escape from cultivation, the flowers manifest a tendency towards unisexuality; that is one plant bears flowers with stamens only, or only the rudiments of the pistil, while on another plant the flowers are bisexual. Exclusively female flowers without stamens do not appear to have been observed. Seedling plants from the cultivated vines often produce unisexual flowers, thus reverting to the feral type. Perhaps the explanation of the fact that some of the cultivated varieties are, as gardeners say, "bad setters,"—*i.e.*, do not ripen their fruit owing to imperfect fertilization,—is to be sought in this natural tendency to diœcism.



Vine. (i.) Flower after fall of petals; magnified. (ii.) Fruit; reduced. (iii.) Foliage, tendril, and inflorescence; reduced.

The conformation of the vine stem has elicited a vast amount of explanatory comment. The most generally accepted explanation is the "sympodial" one. According to this, the shoot of the vine is a "sympode," consisting of a number of "podia" placed one over the other in longitudinal series. Each podium consists of a portion of the stem bearing one or more leaves, each with an axillary bud or buds, and terminating in a tendril or an inflorescence. In *V. Labrusca* there is a tendril opposite to each leaf, so that the podium bears only a single leaf. In other species there is a definite arrangement of the leaves, some with and others without tendrils opposite to them, the numerical order remaining constant or nearly so. These arrangements have doubtless some reference to climatic phenomena, continuity of growth being arrested by cold and promoted by warmth. In any case it is obvious that these facts might be turned to practical ends in cultivation. A vine, for instance, that produces bunches of grapes at each joint is preferable to one in which there are several barren joints, as a larger quantity can be grown within a smaller area. The practice of pruning or "stopping," as explained under HORTICULTURE (vol. xii. p. 247), is consciously or unconsciously regulated by the mode of growth. The tendril or inflorescence, according to the views above explained, though in reality terminal, is bent to one side; hence it appears to be lateral and opposite to the leaf. While the tendril is thus diverted from its original direct course, the axillary bud of the leaf opposite the tendril begins a new podium, by lengthening into a shoot which assumes the direction the tendril had prior to its deflection. This new podium, now in a direct line with its predecessor, produces leaves and ends in its turn in a tendril or inflorescence. A third podium succeeds the second, and so on. Other authorities explain the formation of the tendril and its anomalous position opposite to a leaf by supposing that the end of the stem bifurcates during growth, one division forming the shoot, the other the tendril or inflorescence. It is not possible within the limits at our command to specify the facts and arguments by which these theories are respectively supported. Practically the tendrils assist the plant in its native state to scramble over rocks or trees. As in the case of similar formations generally, they are endowed with a sensitiveness to touch which enables them to grasp and coil themselves round any suitable object which comes in their way, and thus to support the plant. The tendrils of the Virginia creeper (*Vitis* or *Ampelopsis hederacea*[1] the *Parthenocissus quinquefolia* of Planchon) are branched, each branch terminating in a little sucker-like expansion by means of which it adheres firmly to walls or rocks. This is especially noticeable in the Japanese species now so commonly grown against walls under the name of *Ampelopsis Veitchii* (the *Parthenocissus tricuspidata* of Planchon). The extremities of these tendrils turn away from the light, and by this means they are enabled to enter crevices, inside which they expand and fix themselves, just as the lewis or key, used by stonemasons, is fixed into blocks of stone. The anomalous position of the stamens in front of the petals is explained by the abortion or non-development of an outer row of stamens, indications of which are sometimes seen on the hypogynous disk encircling the ovary. The seeds or grape stones are somewhat club-shaped, with a narrow neck-like portion beneath, which expands into a rounded and thickened portion above. On the inner or central side of the seed is a ridge bounded on either side by a shallow groove. This ridge indicates the point of union of the "raphe" or seed-stalk with the seed; it serves to distinguish the varieties of *V. vinifera* from those of other species. In the true vines the neck of the seed is much longer than in the American vines, and the ridge or "chalaza" occupies the upper half of the seed, not the middle portion as in the American kinds. In endeavoring to trace the filiation and affinities of the vine, the characters afforded by the seed are specially valuable, because they have not been wittingly interfered with by human agency. Characters derived from the size, color, or flavor of the berry are of less value for historical or genealogical purposes than those which are the outcome of purely natural conditions.

---

[1] [The Virginia creeper is known as the *Ampelopsis quinquefolia*.—AM. ED.]

The native country of the European vine is considered to be the region south of the Caspian. From this presumed centre it has spread eastwards into Central Asia and westwards to both sides of the Mediterranean, Central Europe, and as far north as Belgium (Planchon). Regel has propounded the notion that the cultivated vine originated as a hybrid between *V. vulpina* and *V. Labrusca*, both North American species; but he offers little evidence in support of his opinion, which has not received the assent of botanists generally. It is interesting to note that grape stones have been found with mummies in Egyptian tombs of not later age than 3000 years. The seeds, according to Engelmann, have the characteristics of those of *V. vinifera*, but show some very slight variations from the type of seed now prevalent. Among the Greeks in the time of Homer wine was in general use. The cultivation of the vine must also have been introduced into Italy at a very early period. In Virgil's time the varieties in cultivation seem to have been exceedingly numerous; and the varied methods of training and culture now in use in Italy are in many cases identical with those described by Columella and other Roman writers (comp. HORTICULTURE, vol. xii. p. 288). Grape stones have been found among the remains of Swiss and Italian lake dwellings of the Bronze period, and others in tufaceous volcanic deposits near Montpellier, not long before the historic era.

The vine requires a high summer temperature and a prolonged period in which to ripen its fruit. Where these are forthcoming, it can be profitably cultivated, even though the winter temperature be very low. Tchihatchef mentions that at Erivan in Russian Armenia the mean winter temperature is 7.1° C. and falls in January to — 30° C., and at Bokhara the mean temperature of January is 4° C., and the minimum — 22° C., and yet at both places the vine is grown with success. In the Alps it is profitably cultivated up to an altitude of 1870 feet, and in the north of Piedmont as high as 3180 feet. At the present time the limit of profitable cultivation in Europe passes from Brittany, lat. 47° 30′, to beyond the Rhine by Liége and through Thuringia to Silesia in lat. 51° 55′ (Grisebach). In former centuries vines were cultivated to the north of this region, as, for instance, in Holland, in Belgium largely, and in England, where they might still be grown. Indeed experiments have lately been made in this direction near Cardiff in South Wales. The yield is satisfactory and the wine made, the variety known as Gamay noir, is described as being like still champagne. In the Middle Ages, owing to various causes, the better wines of France and Germany could not be obtained in England except at prohibitive prices; but, when this state of things ceased and foreign wines could be imported, the English consumers would no longer tolerate the inferior productions of their own vineyards. It is also probable that the English mixed sugar or honey with the wine and thus supplied artificially that sweetness which the English sun denied. It is a curious fact that at the present day much or even most of the wine of finest quality is made at or near to the northern limits of possible cultivation with profit. This circumstance is probably explained by the greater care and attention bestowed both on the cultivation of the vine and on the manufacture of the wine in northern countries than in those where the climate is more propitious. The relative inferiority of the wines made at the Cape of Good Hope and in Australia is partly due to variations of climate, the vine not yet having adapted itself to the new conditions, and partly to the deficient skill of the manufacturers. That such inferiority may be expected to disappear is suggested by the success of vine-culture in Madeira and the Canary Islands.

The development of other species of *Vitis*, such as the curious succulent species of the Soudan and other parts of equatorial Africa, or the numerous kinds in India and Cochin China, is of course possible under suitable conditions; but it is obvious that an extremely long period must elapse before they can successfully compete with the product of many centuries.

For currants and raisins, both produced by varieties of the grape-vine, see the respective articles.

Apart from their economic value, vines are often cultivated for purely ornamental purposes, owing to the elegance of their foliage, the rich coloration they assume, the shade they afford, and their hardihood.

(M. T. M.)

DISEASES OF VINES.

The organic diseases which affect the vine may be divided into two categories, those caused by insects and those caused by parasitic fungi.

Insect enemies.

Diseases Caused by Insects.—Kaltenbach in 1874 enumerated thirty-two species of insects which injure the vine; and since then others have been added to the list. We here deal only with the most important. Amongst those which attack the leaves and young buds, a small beetle, *Anomala vitis*, one of the *Scarabæidæ*, does great harm in some parts of southern Europe by devouring the soft tissue of the leaves. A genus of weevils, *Otiorhynchus*, contains several species which are injurious to the vine chiefly by the adult beetle devouring the buds. *O. raucus, hirticornis, picipes, nigritus, ligustici*, and *sulcatus* are all reported from various places as doing much damage; the larva of the last-mentioned species attacks the roots of the vine, causing the shoots to be small and ultimately bringing about the death of the plant. Fortunately the members of this genus have no wings, so that the damage they cause is to a great extent localized. The same kind of injury is caused by a small Chrysomeleous beetle, *Eumolpus vitis.* The larva of several *Lepidoptera* attack the vine in the same way, destroying the young buds. Amongst these *Nænia typica, Agrotis tritici*, and *A. pronuba* may be mentioned. The larva of *Tortrix pilleriana* in the early spring weaves the young vine leaves together, and, enclosed in this nest, devours the soft tissue at leisure. The imago emerges from the chrysalis in July and shortly after lays its eggs upon the upper surface of the vine leaf. After a few weeks the caterpillars emerge and continue their work of destruction. *Lethrus cephalotes*, one of the *Scarabæidæ*, is very injurious in vineyards which have a dry sandy soil. The beetles live in pairs in holes in the ground; during the summer the beetle bites off the small young shoots and drags them away to its hole, where it is believed they serve as food for the larvæ. In this way very serious damage is caused to the vine plants. *Rhynchites betuleti*, a weevil, also does much damage to the young shoots and leaves. The grapes are attacked by the caterpillar of a moth, *Conchylis ambiquella*, which lays its egg in the young fruit; and in a similar way the larva of *Graptolitha* (*Conchylis*) *botrana* attacks the flowers and fruit. The larva of the cockchafer, *Melolontha vulgaris*, also does much damage by biting through and devouring the roots. *Coccus vitis* is a small scale insect of a reddish brown color, with irregular black spots in the female, which lives in the bark of old or neglected vines and weakens the tree.

Phylloxera.

By far the most destructive of all insect pests which attack the cultivated vine is *Phylloxera vastatrix.* This much-dreaded insect belongs to the family *Aphidæ* or plant lice of the order *Hemiptera.* The genus contains several species which live upon oak trees. Their proper home is in North America; but they have been found in English vineries since 1863. The symptoms of the disease first appeared in France about the same time, in the neighborhood of Tarascon. From the department of Gard the infection spread south to the sea, and east, west, and north, till the southeastern corner of France was thoroughly infected. Another centre of infection arose a few years later near Bordeaux in Gironde, whence the disease spread till the whole of the southern half of France was more or less severely attacked. The parasite was first discovered in France in the year 1868. The *Phylloxera* has spread to Corsica; it has appeared here and there amongst the vineyards of the Rhine and Switzerland; it is found in Spain and Portugal, Austria, Hungary, Italy, and Greece; and in 1885 its presence was discovered in Australia (Victoria), at the Cape of Good Hope, and in Algeria. Hence it is no exaggeration to say that with very few exceptions its distribution is co-extensive with that of the cultivated grape-vine.

The symptoms of the disease, by means of which an infected spot may be readily recognized, are these. The vines are stunted and bear few leaves and those small ones. When the disease reaches an advanced stage, the leaves are discolored, yellow or reddish, with their edges turned back and withered. The grapes are arrested in their growth and their skin is wrinkled. If the roots are examined, numerous fusiform swellings are found upon the smaller rootlets. These are at first yellowish in color and fleshy; but as they grow older they become rotten and assume a brown or black color. If the roots on which these swellings occur be examined with a lens, a number of minute insects of a yellowish brown color are observed; these are the root-forms (radicola) of *Phylloxera* (Fig. 1); they are about .8 mm. long, of an oval outline, and with a swollen body. No distinction between head, thorax and abdomen can be observed. The head bears small red eyes and a pair of three-jointed antennæ, the first two joints being short and thick, the third more elongated, with the end cut off obliquely and slightly hollowed out. Underneath, between the legs, lies the rostrum, which reaches back to the abdomen. The insect is fixed by this rostrum, which is inserted into the root of the vine for the purpose of sucking the sap. The abdomen consists of seven segments, and these as well as the anterior segments bear four rows of small tubercles on their dorsal surface. These root-dwelling insects are females, which lay parthenogenetic eggs. The insect is fixed by its proboscis, but moves its abdomen about and lays thirty to forty yellow eggs in small clusters. After the lapse of six, eight or twelve days, according to the temperature, the larvæ hatch out of the eggs. These are light yellow in color and in appearance resemble their mother, but with relatively larger appendages. They move actively about for a few days and then, having selected a convenient place on the young roots, insert their proboscis and become stationary. They moult five times, becoming with each change of skin darker in color; in about three weeks they become adult and capable of laying parthenogenetic eggs. In this way the insect increases with appalling rapidity: it has been calculated that a single mother which dies after laying her eggs in March would have over 25,000,000 descendants by October. If, however, the insect were content with this method of reproduction, the disease could be isolated by surrounding the infected patches with a deep ditch full of some such substance as coal-tar, which would prevent the insects spreading on to the roots of healthy vines. The fertility of the parthenogenetically-produced insects would also diminish after a certain number of generations had been produced.

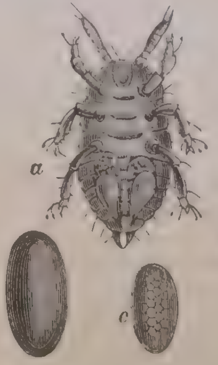


FIG. 3.

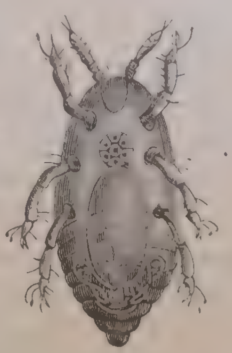

FIG. 4.

FIG. 3.—*a*, Male produced from small egg *c*, laid by winged female (Fig. 2); *b*, large egg; *c*, small egg.

FIG. 4.—Wingless female produced from large egg (Fig. 3, *b*), laid by winged female (Fig. 2).

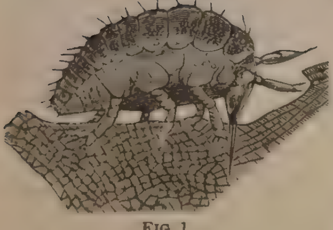

FIG. 1.

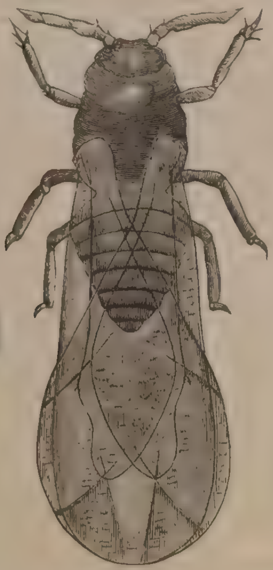

FIG. 2.

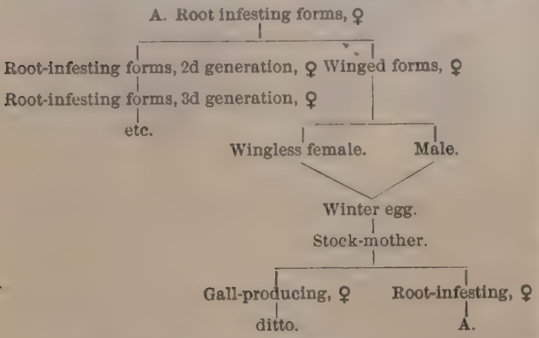
FIG. 1.—Root-inhabiting form (radicola) of *Phylloxera*, with proboscis inserted into tissue of root of vine.

FIG. 2.— *Phylloxera*. Winged female which lives on leaves and buds of vine, and lays parthogenetically eggs of two kinds, one developing into a wingless female, the other into a male.

As the summer wears on a second form of insect appears amongst the root-dwellers, though hatched from the same eggs as the form described above. These are the nymphs, destined to acquire wings; their body is more slender in outline, and at first they bear well-marked tubercles. After several moults the rudiments of two pairs of wings appear, and then the insect creeps up to the surface of the earth, and on to the vine. Here it undergoes its fifth and last moult, and appears as a winged female, capable of reproducing parthenogenetically. The winged form has a slender body with distinct head (Fig. 2). The eyes are well developed, with numerous facets; the antennæ have three joints, the terminal one shaped like that of the root-dwellers. The wings are transparent, with few nervures, and are well adapted for flight. The anterior pair reach far beyond the end of the abdomen; the posterior are narrower and not so long. These winged forms are about 1 mm. long. They fly about from July to October, living upon the sap of the vine, which is sucked up by the rostrum from the leaves or buds. They lay their parthenogenetically produced eggs in the angles of the veins of the leaves, in the buds, or, if the season is already far advanced, in the bark. In very damp or cold weather the insect remains in the ground near the surface, and deposits its eggs there. The eggs are very few in number and of two sizes, small and large (Fig. 4, *b* and *c*). From the larger a female (Fig. 3) is hatched in eight or ten days, and simultaneously, for the first time in the life-history of the *Phylloxera*, a male (Fig. 4) appears from the smaller egg. Neither male nor female has wings; the rostrum is replaced by a functionless tubercle; and there is no alimentary canal. The female is larger than the male and differs from it and the other forms in the last joint of the antennæ. The life of these sexual forms last but a few days, and is entirely taken up with reproduction. The female is fertilized by the male and three or four days later lays a single egg—the winter egg—and then dies. This egg is laid in the crevices of the bark of the vine, and as it is protectively colored it is almost impossible to find it. Here the winter eggs remain undeveloped during the cold months; but in the following spring, as a rule in the month of April, they give birth to a female insect without wings, which resembles the root-dwelling forms, but has pointed antennæ. These forms are termed the stock-mothers; they creep into the buds of the vine, and, as these develop into the young leaves, insert their proboscis into the upper side. By this means a gall is produced on the under side of the leaf. The gall is cup-shaped, and its outer surface is crumpled and covered with small warts and hairs. The opening upon the upper surface of the leaf is protected by similar structures. Within this gall the stock-mother lives and surrounds herself with numerous parthenogenetically-produced eggs,—sometimes as many as two hundred in a single gall; these eggs give birth after six or eight days to a numerous progeny (gallicola), some of which form new galls and multiply in the leaves, whilst others descend to the roots and become the root-dwelling forms already described. The galls and the gall-producing form are much commoner in America than in the Old World.

Scheme of the Various Forms of Phylloxera vastatrix.



The natural enemies of the *Phylloxera* are few in number: they include some mites,—*Hoplophora arctata Thyroglyphus phylloxeræ*,—and the millepede *Polyxenus lagurus*, which devours the subterranean forms. Innumerable artifices have been proposed to combat the terrible disease caused by this minute insect, but none of them seem to be completely successful. As a rule the means suggested are to render the soil uninhabitable for the root forms by injecting certain chemical poisons. Since the importance of the winter egg in the life-history of the insect was demonstrated by Balbiani, attempts have been made to destroy these eggs by rubbing the branches with a chain-armor glove; or some such contrivance for removing the outer layers of the bark, which should be burnt. Again, certain varieties of American vines, which have the reputation of being *Phylloxera* proof, have been grafted on European stocks; but this has proved to be only a doubtful success as regards the *Phylloxera*, whilst the wine made from such vines has undoubtedly deteriorated. The treatment which has been most successful is periodically to submerge the vineyard for a period of not less than forty days. Where this plan has been tried, it has been most successful; unfortunately the majority of vineyards are planted on hillsides and other places where this method of treatment is impracticable. The root-dwelling forms do not thrive in a sandy soil; hence vines grown in a district where such soil is found usually escape the disease.

Oidium.

Fungoid Diseases.—The most destructive form of fungoid disease which attacks the vine is caused by a Pyrenomycetus fungus, *Oidium* (*Erysiphe*) *Tuckeri*. The disease was first noticed in England in 1845; in 1849 it appeared at Versailles; by 1851 it had spread through all the wine-producing countries of Europe, being especially virulent in the lands bordering on the Mediterranean; and in the following year it made its appearance in Madeira. There is little doubt that, like the *Phylloxera*, the *Oidium* is in its origin American. The disease is characterized by the appearance of a white mycelium on the young leaves; this spreads quickly and attacks the older leaves and branches, and ultimately reaches the grapes. At first these are marked only by small brown spots; but the spots spread and fuse together, the skin of the grape is destroyed, and the flesh decays, the seed only remaining apparently untouched. The disease spreads by the mycelium growing over the epidermis of the plant. The hyphæ composing the mycelium are provided with haustoria, which project into the cells of the affected part. Some of the hyphæ which project from the leaf bear conidia, which are constricted off one at a time, and it is by their means that the fungus spreads. The perithecia have not yet been discovered in Europe. But it is not impossible that this stage of the life-history of *Oidium* exists in the United States in the form of *Uncinula spiralis*, which causes a widely spread disease amongst the American vines. The *Oidium* is in its turn attacked by a fungus of the same tribe, *Cicinnobolus Cesatii*, De By, which lives parasitically within the hyphæ of its host, and at times even succeeds in destroying it. The means which have proved most efficacious, both as a remedy and a preventive of this disease, is to scatter flower of sulphur over the vines, before the morning dew has evaporated. Another method is to boil one part of lime with three parts of sulphur, and to sprinkle the mixture over the affected plants.

Peronospora viticola.

Another fungus which attacks vines, especially those of America, is *Peronospora viticola*. The mycelium spreads through the green parts of the plant, attacking the leaves, twigs, and unripe grapes. On the upper side of the leaf, where it is first visible, it forms pale green irregular spots, which become darker in color. On the under side of the leaf these patches are white and are composed of the spore-bearing hyphæ. The leaf ultimately becomes dried up and brittle. The grapes which are attacked cease to grow, turn brown or white, and ultimately dry up and fall off. This disease has been successfully treated with a spray of copper sulphate and lime, or sulphate of iron; solutions of these salts prevent the conidia from germinating.

Anthracnose.

Anthracnose is the name usually given to a disease which was formerly known as "charbon," "pech," or "brenner." This disease is caused by the parasitism of *Sphaceloma ampelinum*, one of the Pyrenomycetous fungi. The fungus assails all the green parts of the vine, and injures the leaves and young shoots as much as it does the grape itself. The first sign of its presence is the appearance of a minute spot, which is grayish in the centre, with a brown border. This spot increases in size; in the stalks it assumes an oval shape, with its long axis parallel to the stalk, whilst in the leaves and grapes it is more or less circular in outline. The centre of the spots on the grapes becomes darker as the disease advances, and a red line appears dividing the dark brown border into an outer and an inner rim and giving a very characteristic appearance to the diseased plant. The berries do not shrivel up as those do that are affected by the black rot. The mycelium of *Sphaceloma* grows just beneath the cuticle of the vine, through which it soon bursts, giving rise to a number of minute hyphæ, which bear conidia. These are minute, oval, colorless spores, which serve to spread the disease over the vineyard and from place to place. The complete life-history of this form is at present unknown; and information as to where the fungus passes the winter, and in what form, would probably afford some useful indications as to the method that should be adopted to combat the disease. Anthracnose has been known in Europe for many years, but has only been observed in America since 1881, whither it was probably imported from the Old World. As a preventive to its attack a solution (50 per cent.) of iron sulphate has been found very useful, as well as care in planting on well-drained soil that does not lie too low, the disease seldom appearing in dry, well-exposed vineyards.

Black rot.

The black rot, like the *Oidium* and *P. viticola*, is American in its origin. It has been known and observed there since 1848, but appeared for the first time in France in 1885. The disease is caused by a fungus, *Physalospora Bidwellii*, Sacc. (*Phoma uvicola*), one of the *Pyrenomycetes*, and by some authorities it has been considered to be a further stage in the life-history of *Sphaceloma*. The fungus confines its attacks to the grapes, the leaves and stems being rarely if ever affected. The grapes are not assailed until nearly full-grown, when a brownish spot appears, which spreads over the whole grape. The latter at first retains its plumpness, but on the appearance of little black pustules, which first occur on the part first affected, the grape begins to shrivel. This continues until the grape is reduced to a black hard mass, with the folds of skin pressed closely against the seed. The disease does not spread from grape to grape, so that as a rule only a certain number of grapes in a bunch are destroyed. The hyphæ of the mycelium of this fungus are septate with numerous short branches. The pustules on the surface are due to fructifications, pycnidia, and spermagonia. The presence of conidia has also been recently demonstrated. The fungus passes the winter in the withered grapes which fall to the ground; hence every care should be taken to collect these and burn them. The use of the solutions mentioned above may also be recommended as a preventive.

Other fungi.

Among the other fungi which infest the vine may be mentioned *Phyllosticta viticola* and *Ph. Labruscæ*, which, when the attack is severe, cause the destruction of the leaves, the only part they assail. These, like the foregoing, are members of the *Pyrenomycetes*. To the same class belongs also *Cercospora vitis* (*Cladosporium viticolum*), which has club-shaped spores of a green-brown color. This also attacks the leaves; but, unless the season is extremely unfavorable, it does little harm.

A very disastrous root-disease of the vine is due to the ravages of the fungus *Dematophora necatrix*, which forms subterranean strings of mycelium—so-called rhizomorphs—the fructification of which is as yet not known; it forms conidia and sclerotia, however, and presents certain analogies to the *Discomycetes*. The diseased roots have been confounded with those attacked by *Phylloxera*. The only mode of combating the malady seems to be to uproot the plants and burn them. Isolation of the diseased areas by means of trenches has also been practiced. This fungus has extended its ravages considerably in southern France and Switzerland within the last ten years. (A. E. S.)

VINEA. See VIGNA.

VINEGAR is a dilute form of acetic acid, having a flavor that varies according to the source from which it is obtained. Vinegar has been known from the earliest historical period, and its power of acting on and dissolving mineral substances rendered it an important agent in the hands of the alchemists. They were, however, unacquainted with pure acetic acid; the most concentrated solution they possessed, called *spiritus veneris*, was obtained by distillation from cupric acetate (verdigris). The nature of acetous fermentation, and the rationale of the processes by which vinegar is prepared, are explained under FERMENTATION (vol. ix. p. 86); and the acetic acid obtained by the destructive distillation of wood is dealt with under TAR (vol. xxiii. p. 62–3). Here we have to do only with the various kinds of vinegar used for table, medicinal, and other household purposes. Malt, wine, and beetroot vinegars are made by the slow process, whilst for the quick method dilute brandy or other spirit is most largely employed.

Malt Vinegar is the preparation commonly manufactured in the United Kingdom, the high alcoholic duties there excluding the use of spirits in the industry. A fermented wort is prepared, as in brewing, which is run into casks laid on their side, bung-hole upwards, till they are three-fourths filled. These casks have a hole bored in each end near the top, and between the three holes a constant circulation of air is secured over the surface of the liquid. The casks are disposed in low-roofed vaults, artificially heated, in which free circulation of air is kept up; but sometimes the process is carried on in the open air in what is termed a vinegar field. According to the temperature (which should be about 70° Fahr.) and other conditions, the acetification of the wort may occupy from weeks to months. From the casks the vinegar is transferred to large tuns provided with false bottoms, over which a thick layer of stalks and skins of grapes and raisins, etc., termed rapes, is strewn. Through this the vinegar is filtered from one tun into another, whereby it is cleared from mucilaginous matter and the last traces of alcohol are thoroughly oxidized. *Wine vinegar* is made in France and other vine-cultivating countries from wine lees and inferior wines. The finest vinegar is yielded by white wines, the product being purer, pleasanter, and generally stronger than ordinary malt vinegar. Vinegar is also largely prepared from beetroot, from the juice of other saccharine vegetables and fruits, and from sugar; and indeed all sources of alcohol may be regarded as possible materials for making vinegar. *Quick method vinegar* is made, principally in Germany, from dilute spirit (about one of proof spirit to six of water), to which are added small proportions of sugar, honey, or malt extract. The standard liquor used by different manufacturers varies considerably.[1] The process is also used to some extent in England for converting fermented and clarified malt wort into vinegar. Commercial vinegar varies much in strength. What is termed "proof" vinegar contains 4.6 per cent of real acetic acid; and, as it requires twenty-four grains of anhydrous carbonate of soda to neutralize each fluid ounce, it is also known as No. 24. In the same way weaker qualities are known as No. 22, No. 20, etc., these figures indicating the grains of carbonate of soda which neutralize a fluid ounce.

Vinegar is extensively consumed in the preparation of pickles and sauces, and as a table condiment, especially with salad vegetables and fish. For many culinary purposes it is flavored with aromatic herbs and spices. Aromatic vinegar, made from glacial acetic acid and perfumes, possesses a refreshing stimulating pungency, as is familiarly known by its use in vinaigrettes. Marseilles vinegar, or thieves' vinegar, is an aromatic preparation used as a prophylactic and masker of evil odors. Vinegar is also a menstruum for several medicinal agents; and in a concentrated condition it is a valuable rubefacient and external stimulant.

VINET, ALEXANDRE RODOLPHE (1797–1847), a French critic, though not a Frenchman, was born near Lausanne on 17th June, 1797. He was educated for and duly entered the ministry of the Protestant Church, the date of his ordination being 1819. He had, however, already acquired an important position as teacher of the French language and literature in the gymnasium at Basel, and during the whole of his life he was more of a critic than of a theologian, though he exercised some influence in the latter capacity, headed a secession from the national church in Vaud, was for a time professor of theology at Lausanne, and advocated an extreme toleration in the matter of religious formulas, together with the separation of church and state. As a theologian Vinet would already have been long forgotten, despite some sermons and treatises which had a certain vogue in his native country, and, being in part translated into English, exercised some influence on English-speaking adherents of Calvinism. His performances as a literary critic, which for the most part represent his academic lectures, are, however, of greater importance. By procuring for Sainte-Beuve an invitation to lecture at Lausanne on Port-Royal, he was the cause of one of the capital works of recent French literary history. But be had less indirect titles to fame in the same department than this. Like all other French writers of repute in Switzerland, he has been accused by French-born censors of that mysterious patavinity which is supposed to attach to Swiss French, and which has been illustrated in such a remarkable fashion by Rousseau, Benjamin Constant, Joseph and Xavier de Maistre, Töpffer, and others. But the persons thus branded were probably content to write French as well as Livy wrote Latin. Vinet's *Chrestomathie Française* (1829) his *Études sur la Littérature Française au XIX ème Siècle* and his *Histoire de la Littérature Française au XVIII ème Siècle*, together with his *Études sur Pascal*, *Etudes sur les Moralistes des XVI ème et XVII ème Siècles*, *Histoire de la Prédication pendant les Réformes*, and other books gave evidence of a wide knowledge of literature, a sober and acute literary judgment, and a very considerable faculty of appreciation. On the whole, he belongs to the academic school of critics rather than to the romantic-impressionist school, or to that rarer and better school than either which adjusts its theories to the work which is brought before it, and condemns nothing so long as it is good work according to the writer's own standard. He had considerable affinities in this last, and his work, having the singular advantage of being in some sort foreign criticism, without undergoing the disadvantage which attaches in French eyes to all criticism of French affairs written in a foreign language, has had a great influence on France. Vinet died on 15th May, 1847, at Clarens (Vaud). A considerable part of his works was not printed till after his death.

VINNITSA, a district-town of Russia, in the government of Podolia, is situated on the Bug, 137 miles to the northeast of Kamenets-Podolsk, and 29 by rail from the Zhmerinka junction on the railway from Odessa to Lemberg. It was founded in the 14th century, but nothing now remains of its two stone forts. Its old Jesuit college is now a gymnasium. Owing to the great fertility of the neighborhood, there are a number of distilleries; and the Vinnitsa merchants, mostly Jews, carry on trade in corn and spirits. The population in 1884 was 18,580.

VIOL. See VIOLIN.

VIOLET. The violets comprise a genus of at least one hundred, some say two hundred species, found principally in temperate regions of the northern hemisphere; a few also occur in mountainous districts of South America, while the genus is not wholly without representatives in Australia. The species are mostly low-growing herbs with alternate leaves provided with large leafy stipules. The flowers are solitary, or rarely in pairs, at the end of slender axillary flower stalks. The flowers themselves are very irregular in form, with five sepals prolonged at the base, and five petals, the lowest one larger than the others and provided with a spur. The five anthers are remarkable for the petal-like processes which extend beyond the anther cells and form a sort of cone around the style. The ovary is superior, one-celled, with three parietal placentas and numerous ovules. It is surmounted by a single style, which terminates in a dilated or hook-like stigma. The fruit is a capsule bursting loculicidally, *i.e.*, through the centre of each of the three valves. The irregular construction of the flower is evidently connected with fertilization by insect agency. To reach the honey in the spur of the flower (of the pansy), says Müller, the insect must thrust its proboscis into the flower close under the globular head of the stigma. This lies in the anterior part of a groove fringed with hairs on the inferior petal. The anthers shed their pollen into this groove, either of themselves or when the pistil is shaken by the insertion of the bee's proboscis. The proboscis, passing down this groove to the spur, becomes dusted with pollen; as it is drawn back, it presses up the lip-like valve (of the stigma) so that no pollen can enter the stigmatic chamber; but as it enters the next flower it leaves some pollen on the upper surface of the valve, and thus cross-fertilization is effected. It is curious, however, that in the common violet, *V. odorata* and other species "cleistogamic" flowers occur of a greenish color, so that they offer no attractions to insect visitors and their form is correspondingly regular. In such flowers self-fertilization is compulsory and very effectual, as seeds in profusion are produced.

---

[1] [Cider is an extensive source of vinegar in the United States, and in it malic acid is usually present.—AM. ED.]

Several species of *Viola* are native to Great Britain. *V. odorata* is highly prized for its fragrance, and in cultivation numerous varieties have originated. The garden pansies or heartseases are derivatives from *V. tricolor*, a cornfield weed, *V. altaica*, and *V. grandiflora*. They are reputed to have been first raised about 1810 by Lady Mary Bennet, with the assistance of her gardener, Mr. Richardson, the term pansy or *pensée* having been long attributed to *V. tricolor*. The variety and richness of coloring in these flowers are very remarkable. "Bedding violas," which differ from pansies in some slight technical details, have been raised by crossing *V. lutea* with *V. calcarata*. The violas are credited with powerful emetic and diuretic properties, on which account they have been admitted into some of the pharmacopœias; but they are now very little used.

Description of the instrument.

VIOLIN, a stringed instrument employed in orchestral and chamber music. The body is a resonant box, composed of a belly, back, and six ribs, all shaped out of thin wood to various curves, the belly and back being scooped out of solid slabs, and the ribs planed and bent. The whole is glued together upon six internal blocks. Pine is used for the belly, maple for the other parts. The external surface is covered with a fine hard varnish of a brown, red, orange, or yellow color, which renders the box more resonant. To this box is glued a solid neck or handle, slightly inclined to the plane of the box, and along the whole instrument four gut strings are stretched by means of as many pegs and a tail-piece. They are tuned in fifths, thus—and set in vibration with a bow, strung with horsehair well rubbed with rosin, which is held in the right hand, the scale being completed by stopping the strings with the fingers of the left hand, in which the instrument is held, on an ebony finger-board glued to the handle, and projecting over the body of the fiddle. The movable bridge, across which the strings are strained, forms the spring or mechanical centre of the violin, and answers to the reed in wood wind-instruments. It has two feet, of which the treble or right-hand one rests firmly on that part of the belly which is supported by a sound-post resting on the back, thus forming a rigid centre of vibration, while the base or left-hand foot, resting on the freely-vibrating part of the belly, communicates to it, and through it to the air in the box, the vibrations which the bow excites in the strings. The belly is strengthened, and its vibration regulated and increased, by a longitudinal bar glued inside it exactly under the bass foot of the bridge. Two incisions in the belly, called sound-holes, from their letting out the sound, also facilitate and modify the vibration. The middle pair of ribs on each side have an inward curvature, to afford the bow better access to the strings. The superficial area of the belly is divided by the bridge into two approximately equal parts, for an obvious acoustical reason;[1] but the upper half is longer and narrower than the lower, which is relatively short and broad. This device gives greater length to the vibrating portion of the strings, and hence greater compass to the instrument. It also brings the bowing place on the strings nearer to the player.

Descent of violin.

Lyre.

Viol.

The bow.

The violin, as the name imports, is a modified form of the viol, an instrument constructed on exactly similar principles, though different in every detail. It dates from the middle of the 16th century; the viol was perfected somewhat earlier. During two centuries the two instruments were in use contemporaneously; but the violin class gradually drove the viols from the field, on the principle, which governs the general history of musical instruments, of the "survival of the loudest." The primitive viol is a modified form of the lute; and the lute is an adaptation of the small lyre of classical antiquity, the name of which (*fidicula*) survives in both groups of the common names for bowed instruments (fidicula, fidula, fideille, vielle, fidel, vedel, fiedel, fiddle; in the Romance group, vidula, viula, viola, violino, violone, violoncello). The fidicula or lyre consisted of a resonant box, having a yoke (*jugum* or *transtillum*) instead of a neck, and one string for each note. Obviously, by substituting for the *jugum* a handle or neck, and thus enabling the fingers of the left hand to stop the strings at will, the number of strings and the tension on the box could be diminished, the scale of notes increased, and the task of the right hand facilitated. By this improvement the class of instruments denominated lyre developed into the lute class; and by other improvements upon the original basis it developed into the harp. The origin of the peculiar mechanism which, when added to the lute, produced the viol, viz., the movable bridge, sound-post, and bow, is obvious. The bow is a development of the plectrum employed for sounding the lyre. The bridge was borrowed from the Greek *κανών*, or monochord. Movable bridges (*ὑπαγωγεῖς*, *subductaria*, *ponticuli*) were employed to divide the the monochord so as to produce the intervals of the various scales.[2] The sole use of this instrument being to train the ear of singers, it may well be supposed that musicians would endeavor to render the tone continuous, the better to support the voice; and this could be readily done by substituting for the plectrum a common military bow, with the string well rubbed with rosin,[3]—a substance largely used by the Greeks and Italians. This supposition is confirmed by the fact that the marine trumpet, the most primitive of bowed instruments, is simply a bowed monochord. Although we can point to no pictorial representation of the bow as applied to musical instruments earlier than the 10th or 11th century, it is reasonable to conclude that the bridge and bow were adapted to the monochord and fidicula during the later empire. A substitute for the bow was afterwards found in the rosined wheel and handle, doubtless first applied to the monochord, afterwards perfected in the large mediæval organistrum, and still employed in the smaller vielle or hurdy-gurdy. The bow, however, held and still holds its ground as the most convenient means of producing continuous tone from stringed instruments. The substitution of a hank of horse-hair for the single bow-string dates from very early times.

---

[1] In order that the vibrational impulse may be given as nearly as possible at the centre of the mass of air in the resonant box.

[2] Meibomius, *Auctores Musicæ Antiquæ*, Amsterdam, 1652, p. 89.

[3] Rosin, manufactured as now from turpentine, was generally used in Italy and Greece in the preparation of wine (Pliny, *N.H.*, xiv. 20, 25), as an ingredient in medicine, and as a cosmetic (Scribonius Largus, *Compos.*, 137 *sq.*). Violin rosin is called in French *colophane* and in German *colophonium*, from the town of Colophon; and Colophonian rosin is described by Pliny as "præ cæteris fulva, si teratur alba fit, gravior odore." Good violin rosin answers exactly to this description.

Geige, crowd, rebec, and fidel.

Except the marine trumpet or bowed monochord, we find in Europe no trace of any large bowed instruments before the appearance of the viol in the 15th century. The geige, crowd, rebec, and fidel, as the small bowed instruments of the Middle Ages were variously called, were small enough to be rested on the shoulder during performance, and were usually rather smaller than the modern violin. It is not easy to assign each of these names to any particular form of instrument. They all had in common a resonant box, either circular, oval, or semi-pearshaped, a handle with a finger-board, a tail piece, a bridge, and from two to four strings tuned to fourths or fifths. The pegs were set vertically to the handle above the finger-board as in the modern guitar. The bow, which was short and clumsy, had a considerable curvature, and the string a high tension. None of these instruments can have had a deeper compass than a boy's voice. The use of the fidel in the hands of the troubadours, to accompany the adult male voice, explains the attempts which we trace in the 13th century to lengthen the oval form of the instrument. A contrary curvature, as in the guitar, was then given to the sides of the resonant box, to enable the bow to reach the strings of the enlarged instrument. This may be denominated the troubadour's fiddle.

Side-blocks and corner-blocks.

The invention next to be described formed the turning-point in the history of bowed instruments. In order to keep in place the ribs of the troubadour's fiddle, with their troublesome contrary flexures, side-blocks inside the instrument were probably used. By cutting these blocks with an angle towards the outside, dividing each side rib into three smaller ones, and giving the middle one on each side a contrary curve so as to meet the upper and lower ribs at an angle on the block, the resonant box was greatly strengthened, its construction became easier, and it became possible to make instruments of indefinitely larger size. Corner-blocks thus converted the fidel into the viol. Single corner-blocks (contrary flexures being still given to the upper ribs) were sometimes used, and often occur later on; but double corner-blocks came at once into general use, and resulted in the construction of the viol in several sizes. The mediæval fiddle appears originally to have had a perfectly flat belly like the lute. It must early have been discovered that a belly scooped out to a slight curve offered greater resistance to the pressure of the strings transmitted by the bridge. Bellies thus scooped out probably came into general use with the invention of corner-blocks. The back continued to be, and in the viol family has always been, a piece of flat joinery. Theoretically, no doubt, this is right; for a scooped-out back is false in construction, as there is nothing for the arch of the back to carry. But, as a back thus modelled and forming a duplicate of the belly, as in the violin, produces a much more powerful tone, this consideration has come to be disregarded.

The viol family.

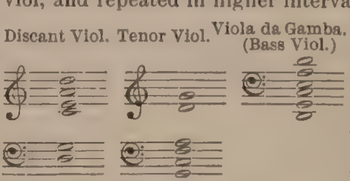
The viol is an instrument, or rather family of instruments, of merit and interest, though now superseded by the violin, with the exception of the double bass, which still survives as a practical instrument. The following are the points in which the viol differs from the violin :

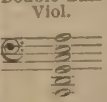
The Viol has—	The Violin has—
1. A flat back of joiner's work.	1. A scooped-out back, modelled like the belly.
2. Shoulders with a contrary flexure in the pattern, and an oblique slope in the back.	2. Square shoulders, and a top like the bottom.
3. A high bridge mounted on legs.	3. A low bridge with feet only.
4. C-shaped, sometimes "flaming sword," sound-holes.	4. *f*-shaped sound-holes.
5. A thin broad handle.	5. A thick narrow handle.
6. Six or seven strings, tuned by fourths and a third.	6. Four strings tuned by fifths.
7. Square or obtuse corners.	7. Acute corners.
8. Deep ribs.	8. Shallow ribs.
9. A soft penetrating tone.	9. A ringing brilliant tone.

Discant viol.

Double bass viol.

In the matter of 4 and 7 a few viols, made after the violin had been perfected, and chiefly Italian, follow the violin. The modern double bass also follows the violin in these points and in 5. The viol was made in three main kinds,—discant, tenor, and bass,—answering to the cantus, medius, and bassus of vocal music. Each of these three kinds admitted of some variation in dimensions, especially the bass, of which three distinct sizes ultimately came to be made—(1) the largest, called the concert bass viol; (2) the division or solo bass viol, usually known by its Italian name of viola da gamba; and (3) the lyra or tablature bass viol. The normal tuning of the viols, as laid down in the earliest books, was adapted from the lute to the bass viol, and repeated in higher intervals in the rest. The fundamental idea, as in the lute, was that the outermost strings should be two octaves apart—hence the intervals of fourths with a third in the middle. The highest, or discant viol, is obviously not a treble but an alto instrument, the three viols answering to the three male voices. As a treble instrument, not only for street and dance music, but in orchestras, the rebec or geige did duty until the invention of the violin, and long afterwards. The discant viol first became a real treble instrument in the hands of the French makers, who converted it into the quinton. The double bass, the largest of the viols, is not a legitimate member of the family, having no corresponding voice, and being from the purely musical point of view superfluous. It appeared, however, concurrently with the bass, as soon as the invention of corner-blocks made it possible to construct bowed instruments of a size only limited by the possibility of playing them. As the discant viol is determined in size by the proportions of the bent arm, the tenor viol by the height above the knee of a sitting player, the bass by a relative height when the instrument is held between the knees, instead of supported on them, so the double bass is determined in size by the height of the standing figure, the bottom of the resonant box resting on the ground. In this respect it corresponds with the marine trumpet, which afforded an obvious hint for its construction. Originally it was made for six strings, the tuning being as follows :



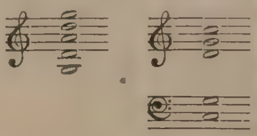


In imitation probably of the largest register of pipes on the improved organs which were then being built, the double bass viol was used as a sub-bass. For this purpose the three highest strings were probably soon found to be useless, and they must have been very liable to break; and, as the pressure of useless strings impairs the resonance of the instrument, they seem to have been gradually dropped. The three lowest strings are the same as those used for the modern double bass.

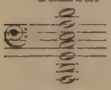
Development of the viols.

The earliest use of the viols was to double the parts of vocal concerted music; they were next employed in special compositions for the viol trio written in the same compass. Many such works in the form of "fantasies" or "fancies," and preludes with suites in dance form, by the masters of the end of the 16th and 17th centuries, exist in manuscript; a set by Orlando Gibbons, which are good specimens, has been published by the English Musical Antiquarian Society. Later, the viols, especially the bass, were employed as solo instruments, the methods of composition and execution being based on those of the lute. Most lute music is in fact equally adapted for the bass viol, and *vice versa*. In the 17th century, when the violin was coming into general use, constructive innovations began which resulted in the abandonment of the trio of pure six-stringed viols. Instruments which show these innovations are the quinton, the lyre, and the viola d'amore. The first-mentioned is of a type intermediate between the viol and the violin. In the case of the discant and tenor viol the lowest string, which was probably found to be of little use, was abandoned, and the pressure on the bass side of the belly thus considerably lightened. The five strings were then spread out, as it were, to the compass of the six, so as to retain the fundamental principle of the outer strings being two octaves apart. This was effected by tuning the lower half of the instrument in fifths like the violin and the upper half in fourths. This innovation altered the tuning of the treble and tenor viols, thus—One half of the instrument was therefore a viol, the other half a violin, the middle string forming the division. The tenor viol thus improved was called in France the quinte, and the treble corresponding to it the quinton. From the numerous specimens which survive it must have been a popular instrument, as it is undoubtedly a substantially excellent one. The relief in the bass, and the additional pressure caused by the higher tuning in the treble, gave it greater brilliancy, without destroying the pure, ready, and sympathetic tone which characterizes the viol. While the tendency in the case of the discant and tenor was to lighten and brighten them, the reverse process took place in that of the bass. The richer and more sonorous tones of the viola da gamba were extended downwards by the addition of a string tuned to double bass A, thus—Marais, a French virtuoso, is usually credited with this improvement; and this extended compass is recognized in the classical viola da gamba writings of Sebastian Bach and De Caix d'Hervelois. The result, however, was not universally satisfactory, for Abel used the six-stringed instrument; and the seven strings never came into general use in England, where the viola da gamba was more generally employed and survived longer than elsewhere.

Treble Quinton. Quinte or Tenor Quinton.



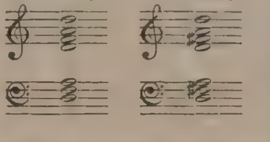
Seven-stringed Viola da Gamba.



Sympathetic strings.

The want of positive power, which is the weakness of the viol and ultimately drove it from the field, must have been early noticed on a comparison of its delicate tones with the harsher notes of the rebec. Hardly had the viol appeared, when makers cast about for means of augmenting its tone. One way of doing this was by additional strings in unisons, fifths, and octaves, a device which had been already employed in the small fiddles of the Middle Ages, and is identical in principle with the augmentation of diapason tone on the organ by means of other registers. The double or treble strung viol, in various sizes, was known as the lyre (Italian, *accordo*); but this multiplication of strings proceeds on a false principle, for each additional string diminishes the resonance of the box, and at the same time hardens the tone and increases the task of the player. More ingenious and successful was the invention of sympathetic metal strings, usually steel, laid under the finger-board, as close as possible to the belly, and speaking by consonance with the notes produced on the bowed strings. From this resonance by sympathy the viol thus strung acquired the general name of *viola d'amore*. The original viola da gamba when so strung came to be called the *viola bastarda;* the seven-stringed bass, with an elaborately perfected sympathetic apparatus, was well known in the 18th century by the name of the *bordone* or baritone, and was a favorite instrument with musical epicures. Instruments made on this principle are found in all sizes; even kits are met with having sympathetic strings (*sordino d'amore*). Violins with sympathetic strings (usually five) are more rare; the viola d'amore chiefly used was of tenor size and compass. Originally tuned as to its bowed strings like the pure tenor viol, an additional string was given it, and the so-called "harp-way" tuning adopted thus— The sympathetic strings were attached to ivory pegs driven into the bottom block, passed through the lower part of the bridge, or over a low bridge of their own, as near as possible to the surface of the belly, under the fingerboard, and were strained to pitch either by means of additional pegs, or, better, by wrest-pins driven into the sides of the peg box and tuned by a key. Originally six, seven, or eight sympathetic strings were used, which were tuned to the diatonic scale of the piece in performance. Later, a chromatic set of twelve strings was employed; and instruments are met with having a double set (24) of chromatic strings, two for each semitone in the scale. With thirty-one strings to be kept in perfect tune, the task of the player must have been arduous indeed; and it is not strange that instruments so elaborate and troublesome were abandoned. In a moist climate like that of Great Britain it is practically impossible to keep a viola d'amore in playing order, the steel strings being in most of their length covered by the fingerboard and out of reach, while the slightest rust impairs the resonance, and much rust renders the instrument completely useless.

Viola d'Amore, flat tuning. Viola d'Amore, sharp tuning.



The violin.

The improvements which were to develop an ultimate bowed instrument for permanent musical use proceeded in the opposite direction to the lyre and viola d'amore: they consisted in increasing yet more the resonance of the box, by making it lighter and more symmetrical and by stringing it more lightly, instead of more heavily. This was really falling back on primitive principles, for the hints were certainly derived from old extant specimens of the crowd and the geige. Existing pictures prove that the oval and the circular geige were made with nearly flat backs and bellies of correlative pattern; and it was natural to seek to reproduce their more powerful tone in the viol by giving it shallower ribs and a back modelled like the belly, and by assimilating the top of the instrument, where the handle is added, to the bottom. This change at once transformed the box of the viol into that of the violin, and the transformation was completed by rejecting the lute tuning with its many strings and tuning the instrument by fifths, as the geige and rebec had always been tuned. The tenor viol was apparently the first instrument in which the change was made, about the middle of the 16th century, and it was so successful that it was quickly applied to the treble and bass instruments.

The question so often mooted, Who invented the violin? may therefore be dismissed. The instrument was produced by applying to the viol certain principles borrowed from its smaller predecessors. It would be equally correct to say that it was produced by applying to the geige other principles borrowed from the viol. Tradition indicates one of the Tieffenbrückers, a German family whose members for more than a century were famous lute-makers in Venetia and Lombardy, as the inventor. The earliest instrument of the violin type known to the present writer is a tenor made by Fr. Linaroli of Bergamo, at Venice, in 1563; and the earliest makers whose authentic works have descended to us in considerable numbers are Gaspar da Salò and Maggini, both of Brescia.

High and flat modelled violins.

An important distinction should be mentioned which divides violins into two classes, known respectively as the "high" and the "flat" model. On this subject much has been said and written; but it has not been discussed scientifically, nor has the prevalence of one model over the other at different times and in different places been accounted for. It is understood that, while the flat model, which has now practically driven the high model from the field, yields a tone that is more powerful and travels further, the high model yields a tone which comes out more readily, and is softer and more flute-like, although less capable of light and shade. The high model is less convenient for the player, because when the instrument is rested on the clavicle the strings are at a greater altitude in relation to the right arm, which accordingly requires to be raised. Hence the high model has become less popular as the art of violin-playing has developed, and is undoubtedly less suitable to the elaborate system now in use. These remarks apply to instruments of pronounced high model; for the distinction is in fact a matter of degree, and is purely mechanical in origin. The flattest models rise about twelve millimetres above the ribs, while the highest do not exceed twenty, and many of the best violins have an elevation between these limits. The object of the rise being to give just such a degree of resistance to the pressure of the bridge as will set the enclosed air in due vibration, and this degree being approximately the same in all violins, the amount of elevation must obviously be relative to the strength and elasticity of the fibres of the belly. The more regular the shape of the box,—that is, the flatter the model,—the more perfect and the more completely blended will be the undulations of the mass of air within, and the more uniformly sonorous and musical the tone; but owing to the pressure of the strings only strong and elastic wood can be used for this model. Wood of stiff and brittle fibre must be worked to a higher arch, or if used for the flat model must be left too thick for perfect vibration. Hence we might expect to find the flat and the high model employed respectively where different qualities of wood are available, with a corresponding result in the tone. Fine elastic pine is chiefly found on the southern slopes of the Alps; and thereabouts the best viols and violins have always been made. The famous violin-makers carried on their trade at Brescia, Cremona, Mantua, Milan, and Venice, while the Piedmontese Alps and the Apennines furnished material for some makers in Piedmont and at Bologna. High-modelled violins, and flatter instruments of thicker wood and inferior sonority, were chiefly made in Tyrol, Germany, France, and England, where the available material was less tenacious and elastic.

Early Italian makers.

The early Italian school is chiefly represented by the Brescian makers, Gaspar da Salò, Giovanni Paolo Maggini, Giovita Rodiani, and the two Zanettos (1580–1630). It is, however, misleading to denominate it the Brescian school, for its characteristics are shared by the earliest makers of Cremona and Venice. To eyes familiar with the geometrical curves of the later Cremona school most of the violins of these makers, like the early violins of England and Germany, have a rude and uncouth appearance. The height of the model varies; the pattern is attenuated; the *f*-holes share the general rudeness of design, and are set high in the pattern. Andreas Amati of Cremona, the eldest maker of that name, effected some improvements on this primitive model; but the violin owes most to his sons, Antonio and Geronimo, who were partners. Nicholas, son of Geronimo, and Antonio Stradivari, the pupil of Nicholas, each did something to perfect the model; but the substantial improvements which converted the Brescian violin into the modern instrument were the work of Antonio and Geronimo. These improvements, which were, in fact, of an artistic rather than a scientific nature, consisted in modelling the instrument in all its outlines and surfaces to regular curves. Painting and inlaying had long been employed in the decoration of stringed instruments; but the brothers Amati were the first who applied to the violin the fundamental law of decorative art, that the decorative and constructive elements should be blended in their inception: in other words, the construction should be itself decorative and the decoration itself constructive. The nature of the instrument suggested the application of this law, for all extraneous additions to the varnished wood of which it consists tend to damp the tone. Nicholas Amati (1596–1684) made some slight improvements in the Cremona model, and Antonio Stradivari (1649–1737) finally settled the typical Cremona pattern, which has been generally followed; for the majority of violins since made, whether by good or bad makers, are copies of Stradivari. Besides the last-named, the following makers worked generally on the Amati model,—Cappa, Gobetti, the Grancino family, Andreas Guarnieri, and his son Giuseppe, the Ruggieri family, and Serafin of Venice. Balestrieri, the Bergonzi family, Alessandro Gagliano, the earlier members of the Guadagnini family, Montagnana, and Panormo were pupils or followers of Stradivari. Landolfi, Storioni, and Carlo Giuseppe Testore, a pupil of Giovanni Grancino, leaned to the model of Giuseppe Guarnieri del Gesù. Some resemblances, especially in the matter of the varnish, are traceable between the works of makers who lived contemporaneously in the same town, *e.g.*, in Naples, Milan, and Venice.

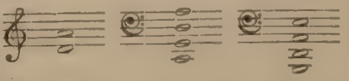
German, English and French makers.

The Amati method was adapted to the higher model by Jacob Stainer of Absam, near Hall in Tyrol, whose well-known pattern was chiefly followed by the makers of England, Tyrol and Germany, down to the middle of the 18th century. It thenceforward fell into disuse, owing to the superior musical qualities of the Cremona violin and to improved means of communication, which enabled the violin-makers of other countries to procure wood sufficiently soft and tenacious to be worked to the flat model. The school of Stainer is represented amongst many others by Albani, Hornsteiner, the Klotz family (who made large numbers of instruments excellent in their kind), Schorn of Salzburg, and Withalm of Nuremberg. The English makers may be divided into three successive groups: 1. An antique English school, having a character of its own (Rayman, Urquhart, Pamphilon, Barak Norman, Duke of Oxford, etc.); 2. Imitators of Stainer, at the head of whom stands Peter Wamsley (Smith, Barrett, Cross, Hill, Aireton, Norris, etc.); 3. A later school who leaned to the Cremona model (Banks, Duke of Holborn, Betts, the Forsters, Gilkes, Carter, Fendt, Parker, Harris, Matthew, Hardie of Edinburgh, etc.). The early French makers have little merit or interest (Bocquay, Gavinies, Pierray, Guersan, etc.); but the later copyists of the Cremona models (Lupot, Aldric, Chanot the elder, Nicholas, Pique, Silvestre, Vuillaume, etc.) produced admirable instruments, some of which rank next in merit to the first-rate makers of Cremona.

Tenor violin and violoncello.

The tenor violin, in compass a fifth lower than the treble violin, appears to have preceded the latter; and from existing specimens we know that the bass violin, now termed the violoncello, with a tuning an octave below the tenor, appeared very shortly afterwards. A double bass violin, tuned a fourth below the violoncello and usually known as the *basso da camera*, completed the set of instruments in violin shape; but from the difficulty attending its manipulation it never came into general use. The celebrated double bass player, Dragonetti, occasionally used the basso da camera, and an English player named Hancock, who dispensed with the highest or E string, is still remembered for his performances on this unusual instrument.

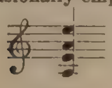
Tenor Violin. Violoncello. Basso da Camera.



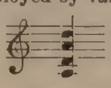
The tenor and violoncello are made on the same general model and principles as the violin, but with certain modifications. Both are relatively to their pitch made smaller than the violin, because, if they were so constructed as to have the same relation to the pitch and tension of the strings as the violin, they would not only have an overpowering tone but would be unmanageable from their size. This relatively diminished size, both in the dimensions of the instrument and in the thickness of the wood and strings, gives to the tenor and violoncello a graver and more sympathetic tone. To some extent this reduced size is compensated by giving them a greater proportional height in the ribs and bridge; the increase is hardly perceptible in the tenor, but is very noticeable in the violoncello. Correlative to this general diminution in the size of the instrument and the tension of the strings as the bass register is entered, there is a progressive diminution in the size and tension of the strings of each instrument, the treble string having in all cases the greatest tension and being thickest in proportion, though actually the thinnest. This is partly due to the fact that the ear demands greater brilliancy and force in the higher register; but it has also a mechanical reason. The treble foot of the bridge is fixed, while the bass foot vibrates freely; additional stability is given to the rigid side and additional freedom to the bass side by lightening the tension in each string progressively towards the bass. This can be verified by the simple experiment of stringing up a violin with the strings reversed, but without altering the sound-post and bass-bar. Still further to lighten the tension on the bass side, the lowest string of the violin and the two lowest of the tenor and violoncello are specially made of thin gut and covered with fine metal wire. Such strings yield a grave tone with comparatively little tension.

Scordatura.

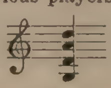
It is obvious that, if the lowest string, or the two lowest strings, are elevated in pitch, the tension will be greater, and the violin will produce a more powerful tone; if the bass string is lowered, the contrary will take place. By adapting the music to this altered tuning (*scordatura*) some novel effects are produced. The following are the principal *scordature* which have been occasionally employed by various players.



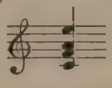
Tartini, Castrucci. (Scotch Reels.)



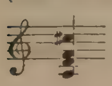
Biber.



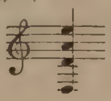
Biber.



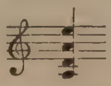
Nardini.



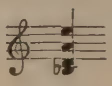
Barbella, Campagnoli.



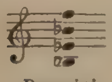
Lolli.



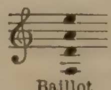
De Bériot, Prume, Mazas, etc.



De Bériot.

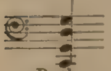


Paganini.



Baillot.

The violoncello is less amenable to the scordatura than the violin; the only classical instance is the tuning employed by Bach in his fifth sonata, which consists in lowering the first string by a tone.



Bach.

It is commonly said that an old violin is better than a new one. Other things being equal, and supposing the older to be in fair preservation, this is true; it is also true that of old violins the best, as a rule, have survived.

"Good" violins.

Good violins, however, have been continuously made, and are still being made, though since the middle of the 18th century the cheapness of the "trade" fiddle, made by the hundred by divided labor, has much circumscribed the business of the higher-class workman. The best workmen of different countries differ little in merit; but it is seldom that any maker out of Italy is successful in varnishing his work so as to impart to it the superior resonance which characterizes the best Italian violins. The varnish, originally merely ornamental and preservative, has become an essential part of the work, from its intimate connection with the tone. The secret of making varnish is not lost, as is sometimes stated; the difficulty consists in applying and drying it with reference to the climate where the operation takes place. In moist climates, oil varnish, which is the best, dries too slowly; hence the use of spirit varnish, which is more manageable, but has not the effect of permeating the superficial tissues of the wood so as to increase and perpetuate its elasticity. Many well-made modern violins, notably those of some French makers, have proved failures, because they have, under a mistaken belief, been made out of old and dry wood. After a few years pine begins to lose its elasticity; the old makers used wood that was only just sufficiently seasoned, and they preserved its elasticity by applying their varnish at once.

It is also commonly said that a flat violin is preferable to a high-modelled one. This must be accepted with some modification. Instruments which are excessively flat should be avoided, for reasons above stated. A moderate height, rather less than the medium, is most favorable to vibration; what is really essential is that the sound-holes should be in horizontal planes, not in planes inclined at a considerable angle to the transverse section of the instrument. Such sound-holes, as may be proved at once by the ear, have the property of immediately letting out the vibrations of the small mass of air which lies directly under the bridge, and thus rob the great mass of air in the body of the fiddle of the impulse necessary to set it properly in vibration; hence the tone, though quickly yielded and not feeble to the ear of the player, is found at a short distance to be deficient in force and flexibility. The violins most in request are the larger specimens of the Amati family, of Stradivari and his best pupils, and of the two cousins Giuseppe Guarnieri,—the instruments of Giuseppe called "del Gesù," from his use of the sacred monogram on his tickets, being by some players preferred to those of Stradivari. For old instruments of the best class, purchasers must be prepared to pay from £200 [$972.00], to £600 [$2916.00], according to their quality and state of preservation. Second-class old Italian instruments, and first-rate specimens of the best school of French copyists, can usually be bought for smaller sums down to £20 [$97.20]. The chief seats of the wholesale violin manufacture are Mirecourt in France and Markneukirchen in Saxony.

Violin bow.

The violin bow, which is made of Brazil wood, was reduced to its present admirable shape about 1780 by François Tourte of Paris (1747–1835), whose bows are still esteemed above all others. A fair Tourte bow is generally worth £10 [$48.60]; but a fine one has been sold for £30 [$145.80]; and one of his best violoncello bows, which are rarities, was recently sold in Paris for £44 [$213.84]. Bows, however, which leave little to be desired are made in great numbers by English, French, and German makers. A good bow is of more importance to a player than a good violin; something may be done with an indifferent instrument, but no one can play with a bad bow.

Strings.

The best strings have always been made in Italy; the climate of northern Europe is unsuitable for the manufacture. Good strings are essential to the player, and they should be frequently changed, as they only retain their shape at the place where the bow touches them, and their elasticity, for a limited period.

For further information on the history of stringed instruments the reader is referred to Vidal, *Les Instruments à Archet*, 3 vols. 4to (Pàris, 1876–79); Rühlmann, *Gesch. der Bogen-Instrumente* (Brunswick, 1882); and the various articles in Grove's *Dictionary of Music and Musicians*. The best handbook of violin makers is Hart's *Violin* (London, 1875–80). The process of violin-making is well described in E. H. Allen's *Violin-Making as it was and is* (London, 1885). A smaller work, which can be recommended, is Maugin's *Manuel du Luthier* (Paris, 1869). The art of playing the violin has been practically treated at length by Campagnoli, Baillot, Spohr, Ferdinand David, Alard, and many other professors of the various schools; but the only attempt to explain it systematically with reference to sound scientific theory is contained in an unpretending *brochure* by Karl Courvoisier (*Die Violin-Technik*, Cologne, 1878), which it is impossible to praise too highly. See also *Musical Instruments, Historic, Rare, and Unique*, by A. J. Hipkins (Edinburgh, 1887). (E. J. P.*)

VIOLLET-LE-DUC, **Eugène Emmanuel** (1814–1879), French architect and writer on archæology, was born at Paris on 27th January, 1814. He was a pupil of Achille Leclère, and in 1836–37 spent a year studying Greek and Roman architecture in Sicily and Rome. His chief interest was, however, in the art of the Gothic period, and, like Sir Gilbert Scott in England, he was employed to "restore" some of the chief mediæval buildings of France, his earliest works being the abbey church of Vézelay, various churches at

Poissy, St. Michel at Carcassonne, the church of Semur in Côte-d'Or, and the fine Gothic town-halls of Saint-Antonin and Narbonne, all carried out between 1840 and 1850. From 1845 to 1856 he was occupied on the restoration of Notre Dame in Paris in conjunction with Lassus,[1] and also with that of the abbey of St. Denis. In 1849 he began the restoration of the fortifications of Carcassonne and of Amiens cathedral; and in later years he restored Laon cathedral, the château of Pierrefonds, and many other important buildings. He was an intimate friend of Napoleon III., and during the siege of Paris (1871) gave valuable help as an engineer to the beleaguered army.[2] He held many important offices, both artistic and political, and was for many years inspector-general of the ancient buildings throughout a large part of France. His last work was the general scheme for the Paris exhibition buildings in 1878. He died on 17th September, 1879.

As a designer Viollet-le-Duc occupied only a secondary place; but as a writer on mediæval architecture and the kindred arts he takes the highest rank. His two great dictionaries are the standard works in their class, and are most beautifully illustrated with very skilful drawings by his own hand. Viollet-le-Duc ,was a man of the most brilliant abilities, endowed with a power of work which has seldom been equalled. He was at once an artist, a man of science, a learned archæologist, and a scholar. His map showing the rock contours and the glaciers of Mount Blanc is a model of its kind, which combines great artistic beauty with the accuracy of the most skilful engineer. His strong poetical fancy enabled him to reconstruct the life and buildings of the Middle Ages in the most vivid way. His principal literary works were the *Dictionnaire de l'Architecture Française du XI. au XVI. Siècle*, 1853-69; *Dictionnaire du Mobilier Français*, 1854-75; *L'Architecture Militaire au Moyen Âge*, 1854; *Habitations Modernes*, 1874-1877; *Histoire d'une Maison*, 1873; *Histoire d'une Forteresse*, 1874; *Histoire de l'Habitation Humaine*, 1875; *Le Massif de Mont-Blanc*, 1876; *L'Art Russe*, 1877; *Histoire d'un Hôtel-de-Ville et d'une Cathédrale*, 1878; *La Décoration appliquée aux Édifices*, 1879; as well as many minor works dealing with separate buildings.

VIOLONCELLO, See VIOLIN.

VIOTTI, GIOVANNI BATTISTA (1753-1824), violinist and musical composer, was born at Fontanetto in Piedmont, on 23d March, 1753. He learned the rudiments of music from his father, a veterinary surgeon and an amateur horn player; and in 1764 Giovannini taught him the violin for a year. Two years later he was placed by the Marchesa di Voghera under the violinist Pugnani at Turin. In 1780 Viotti having already made himself a name, travelled through Germany and Poland to Russia, where the empress Catherine honored him with marks of extraordinary favor. He next appeared in London, in company with Pugnani, and at once achieved a brilliant and lasting reputation. In 1782 he was equally successful in Paris. Two years later he was appointed leader of Prince de Soubise's private orchestra; and in 1788 he undertook the direction of the opera, raising the performances with Cherubini's assistance, to a very high level. Viotti also joined with Feydeau-de-Brou in constructing the famous Feydeau theatre. In 1790 the Revolution compelled him to fly to England; but a charge of Revolutionary espionage drove him for a time to Hamburg, whence, however, he returned in 1795. From that time he resided almost uninterruptedly in London until 1818, when he once more settled in Paris, resumed the direction of the opera, and retired in 1822 with a pension. He died in London on 10th March, 1824.

Viotti's playing was distinguished by an extreme purity of style, a magnificent tone, and an endless variety of poetical and imaginative expression. He was undoubtedly the best violinist of the age, and the best composer for his instrument. Among his works are 29 violin concertos, a series of symphonies concertantes for two violins, 45 duos, 18 trios, and 21 quartetts, and a great number of sonatas, notturnos, and other instrumental works. His school was worthily perpetuated by his pupil Rode.

VIPER. The vipers constitute a family (*Viperidæ*) of Old-World, poisonous, viviparous snakes, which have a single movable poison fang on either side of the upper jaw, without any excavation or pit between the eye and the nostril,—thus differing from the *Crotalidæ*. They have a post-frontal and a maxillary bone, which latter is swollen and upright, articulating with the pre-frontal by a ginglymus, and short—not reaching the premaxilla. Vipers are mostly more or less thick-bodied and short-tailed, the head being entirely covered above with small scales, except in a single species. The nose is often recurved, and some scales of the head are elongated so as to form "horns" in several species. The main points in the anatomy[3] of the group have been already described in the article REPTILES, and their zoological relations stated in the article SNAKES.

There is much diversity of opinion as to the classification of the vipers, and, as Dr. Alexander Strauch appears to be the author who has worked out the group with the greatest care and completeness, his classification is here provisionally adopted.

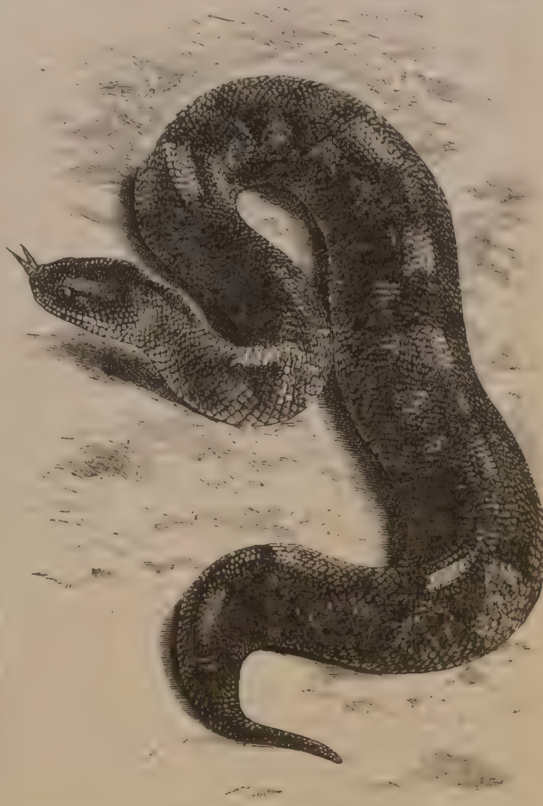


FIG. 1.—*Vipera nasicornis.*

The *Viperidæ* thus consist of three genera, which are distinguished as follows:

(1) Two rows of sub-caudal scales............	*Vipera.* (20 species).
(2) One row of sub-caudal scales—	
a. Gular scales smooth, body rounded or depressed, tail simple	*Echis.* (1 species).
b. Gular scales strongly keeled, body compressed, tail prehensile..........	*Atheris.* (3 species).

The common viper (*V. berus*) is easily distinguished from the harmless ring-snake by the black and white (or yellow) band behind the head, which is generally conspicuous in the latter animal. It is also distinguishable (apart from individual varieties) from the snake *Coronella*, rare in England, by having a dark V-shaped mark on its head and a dark zig-zag line down the back. It is this viper which has the top of the head covered by shields (which may be regular or irregular in outline) instead of small scales only. It is one of the most widely distributed of snakes, being found from northern Spain eastwards to the island of Saghalin, and from the northern boundary of Persia to beyond the Arctic Circle in Scandinavia, though it is not found in Ireland. It inhabits all sorts of situations, though it prefers a dry soil, and it may be met with at an elevation of 9000 feet above the sea. It seeks its prey at night, and penetrating the burrows of mice will eat their nestlings. Its bite is sometimes fatal to large dogs, and occasionally to weakly children. It brings forth in April and May from five to fourteen young, which are hatched as they are born.

---

[1] He published in 1867-69 a fine work showing his not very successful colored decoration applied to the chapels of Notre Dame.

[2] See his *Mémoire sur la Défense de Paris*, 1871.

[3] For a description of the poison fang, see vol. xx. p. 470; and for a figure of the skull, see vol. xx. p. 464.

The other European vipers are *V. aspis*, *V. ammodytes*, and *V. latastii.*[1] *V. aspis* is very like the common viper, save as to the scales on the head and the fact that its snout is somewhat turned up. It inhabits France, Switzerland, and Italy. *V. ammodytes* is a somewhat larger species, with a singular pointed process extending upwards from the snout end. It is found in Egypt, Syria, Asia Minor, Turkey, Greece, southern Austria, and Italy. *V. latastii* is a species intermediate between *V. aspis* and *V. ammodytes*. It inhabits Spain, Portugal, Morocco, and Algiers. Thus, of the four European vipers, two are also found in Africa and one in both Africa and Asia. There are three exclusively Indian vipers,—*V. xanthina*, *V. persica*, and *V. russellii*. *V. xanthina* is an animal about 2½ feet long. As in all the other non-European vipers, the body scales are strongly keeled. It is found in Asia Minor, Syria, and Persia. *V. persica* is, as its name implies, a Persian animal. The scales above each eye are so modified as to form a horn. *V. russellii* is hornless, but very large: it is said to attain a length of more than 6 feet. It is widely distributed, inhabiting India, Burmah, Siam, Ceylon, Sumatra, and Java. Two vipers are common to Asia and Africa. One of these, *V. mauritanica*, extends from Algiers to Persia. It may be nearly 5 feet long. The other species, *V. cerastes*, is a much smaller snake, never being much more than 20 inches in length. It is remarkable for two long pointed horns (which stand up over either eye), and is widely distributed in North Africa and Arabia. All the other species of the genus *Vipera* are exclusively African, and only one is found north of the Sahara. This is *V. avizennæ*. It has no horns, and only attains a length of about 16 inches. *V. superciliaris* is also a small snake, but it has a large rugose supraorbital plate. It comes from Mozambique. The puff-adder (*V. arietans*) is a large thick snake, which may be 4 feet long. It is a very deadly animal, and is widely distributed over southern and central Africa, extending to both the east and west coast of that continent. It is without horns. *V. nasicornis* is a beautifully colored, large, and bulky snake, which may be upwards of 6 feet long. Two horns project obliquely forwards from just in front of either nostril. It inhabits southern Africa. It is a very venomous animal.[2] *V. rhinoceros* is another large snake, which comes from both the east and west coasts. It has a pair of horns upstanding between its nostrils, each clothed with but a single shield. *V. cornuta* has scaly prominences, which are hardly "horns," and which consist each of a group of four or five large upright distinct scales placed above one of the eyes. It is a small snake, hardly ever more than 20 inches long. It inhabits western, southern, and eastern Africa. *V. caudalis* is a still smaller snake, which has a single scale extending upwards over either eye. It comes from southern Africa, as also does *V. schneideri*, which is like the last species, save that it has nothing at all representing horns. *V. inornata* is also hornless, though it has the supraorbital region somewhat elevated. It is a very small snake, only about 15 inches long. It is a South-African species, as also are *V. atropos* and *V. atropoides*, which are both hornless and are about 2 feet long.

The genus *Echis* consists of but one species (*E. carinata*), which has been noticed and figured in the article SNAKES (see vol. xxii. p. 209). It is a viper-like snake, which inhabits desert lands or dry plains, and extends from India through Abyssinia and North Africa to Senegal.

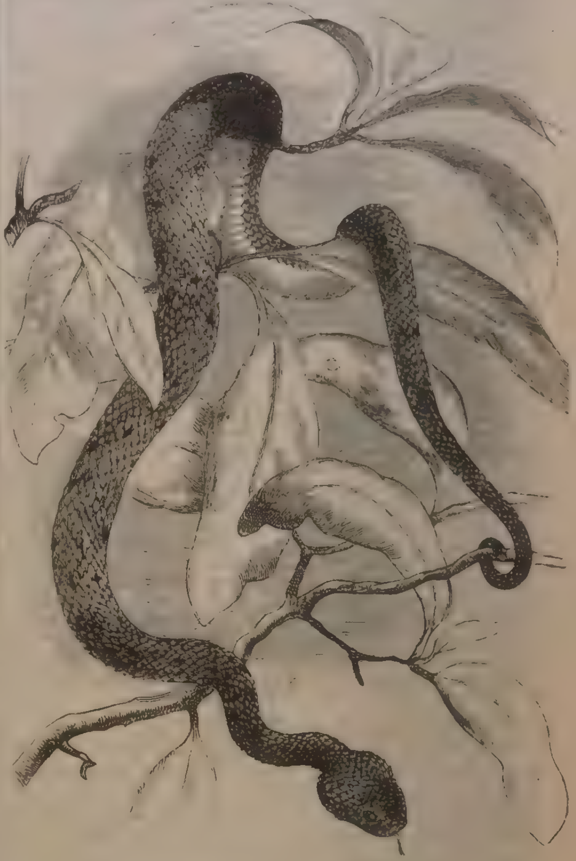

FIG. 2.—*Atheris burtoni*. (Length 12 inches.)

The genus *Atheris* is made up of several more or less problematical species of snakes, all of which present a great contrast to the other. *Viperidæ*, in that they have long, slender, and laterally compressed bodies with prehensile tails—being altogether adapted for arboreal life. Nevertheless the head is decidedly viperine, sharply marked off from the neck, broad behind, and heart-shaped when looked at from above. These animals are assisted in climbing, not only by their prehensive tails, but also the strongly keeled scales beneath the lower jaw. All the so-called species are inhabitants of tropical Africa,—*A. burtoni*, *A. squamigera*, and *A. chloroechis* being found on the west coast. Two new species have been lately discovered, *A. anisolepis* and *A. cæviceps*,—both from the Congo.

The genus *Acanthophis* is sometimes classed with the vipers, but is here excluded on account of its large, truly colubrine head shields. See SNAKES, vol. xxii. p. 209.

The *Viperidæ* are geographically distributed as follows:

Palæarctic Region.[3]—*V. berus*, *V. aspis*, *V. ammodytes*, *V. latastii*, *V. xanthina*, *V. persica*, *V. mauritanica*, *V. cerastes*, *V. avizennæ*, *E. carinata*.

Ethiopian Region.—*V. superciliaris*, *V. arietans*, *V. nasicornis*, *V. rhinoceros*, *V. cornuta*, *V. caudalis*, *V. schneideri*, *V. inornata*, *V. atropos*, *V. atropoides*, *V. burtoni*, *A. squamigera*, *A. chloroechis*. (ST. G. M.)

Indian Region.—*V. russellii*, *E. carinata*.

---

[1] In collections wherein very many specimens are preserved it is possible to find transitional forms between all the four European species.

[2] On one occasion one of these snakes, after giving birth to twenty-one young (which bit and killed mice within five minutes of being born), became very ill-tempered, and when two adult males were placed in her cage she bit one with such violence as to break off one of her fangs, which she left, about three-quarters of an inch in length, sticking in his back. He, however, appeared not to suffer the slightest inconvenience, and was never the worse for it (see *Proc. Zool. Soc.*, 1871, p. 638).

[3] This region includes Europe, Africa north of the Sahara, and Asia north of the Himalayas.

VIRGIL (P. Vergilius Maro) enjoyed in ancient times an unquestioned supremacy among Roman poets. His pre-eminence in poetry was as distinctly recognized as that of Cicero in prose; and among the Romans, as among all nations who have possessed a great poetical and a great prose literature, the superior power of poetry over that of any other mode of artistic expression to embody and perpetuate the true ideal of the national imagination and the deepest vein of national sentiment, was fully recognized. The veneration in which his name was held during the long interval between the overthrow of Western civilization and the revival of letters affords testimony of the depth of the impression which he made on the heart and imagination of the ancient world. The traditional belief in his pre-eminence has been on the whole sustained, though not with absolute unanimity, in modern times. By the scholars and men of letters of the 16th, 17th, and 18th centuries it was never seriously questioned. Only during the first half of the present century has his right to be ranked among the great poets of the world been disputed by eminent German and English critics. The German mind has always been more in sympathy with the art and genius of Greece than of Rome and Italy; and during the first half of the present century, when English criticism first came under German influence, there was a strong reaction from the habitual deference paid to those writers who had moulded literary taste in the previous century. The estimation of Virgil, as the most consummate representative of Latin culture, suffered most from this reaction.

In the present day the effect of this reaction shows itself only in a juster estimate of Virgil's relative position among the poets of the world. It is no longer a question whether he or Homer was best entitled to hold that "sceptre" among the great poets of antiquity which Lucretius awards to the older poet. It may still be a matter of individual opinion whether Lucretius himself was not a more powerful and original poetical force, whether he does not speak more directly to the heart and imagination of our own time. But it can hardly be questioned, on a survey of Roman literature, as a continuous expression of the national mind, from the age of Nævius to the age of Claudian, that the position of Virgil is central and commanding, while that of Lucretius is in a great measure isolated. If we could imagine the place of Virgil in Roman literature vacant, it would be much the same as if we imagined the place of Dante vacant in modern Italian, and that of Goethe in German literature. The serious efforts of the early Roman literature—the efforts of the older epic and tragic poetry—found their fulfilment in him. The revelation of the power and life of Nature, first made to Lucretius, was able to charm the Roman mind, only after it had passed into the mind of Virgil, and been brought nearer to the heart of Romans and Italians by association with the industry most congenial to them. And not only does Virgil absorb and supersede much of what went before him; he anticipates and supersedes much of what came after him. When we have read the *Æneid*, we add scarcely anything to our sense of the capacities of the Italian genius and of the Latin language by studying the artificial epics of the empire. It is enough to read any ten lines of them along with any ten lines of Virgil to feel how absolute is his superiority.

Virgil is the only complete representative of the deepest sentiment and highest mood of his countrymen and of his time. In his pastoral and didactic poems he gives a living voice to the whole charm of Italy, in the *Æneid* to the whole glory of Rome. He was in the maturity of his powers at the most critical epoch of the national life, one of the most critical epochs in the history of the world. Keeping aloof from the trivial daily life of his contemporaries, he was moved more profoundly than any of them by the deeper currents of emotion in the sphere of government, religion, morals, and human feeling which were then changing the world; and in uttering the enthusiasm of the hour, and all the new sensibilities that were stirring in his own heart and imagination, he had, in the words of Sainte-Beuve, "divined at a decisive hour of the world what the future would love." He was also by universal acknowledgment the greatest literary artist whom Rome produced. It was an essential condition of Roman more than of any other great literature that it was based on culture and education. Not only the knowledge but the inspiration of Greek poetry—"spiritus Graiæ camenæ"—was the condition of Roman success in poetry. Virgil had not only more learning and culture, but had a more catholic sympathy with the whole range of Greek poetry, from Homer and Hesiod to Theocritus and the Alexandrians, than any one else at any period of Roman literature. Greek studies were in his time pursued with greater ardor, completeness, and thoroughness than at any previous period. The effort of the preceding generation to attain to beauty of form and finish of artistic execution found in him, at the most susceptible period of his life, a ready recipient of its influence. The rude dialect of Latium had been moulded into a powerful and harmonious organ of literary expression by the emotional ardor and vigorous understanding of a long series of orators; the rough and unhewn structure of the Latin hexameter, first shaped by Ennius to meet the wants of his own spirit and of his high argument, had been smoothed and polished by the congenial labor of Lucretius, and still more perfected by the finer ear and more careful industry of Catullus and his circle; but neither had yet attained their final development. It was left for Virgil to bring both diction and rhythm to as high a pitch of artistic perfection as has been attained in any literature.

The great work which he accomplished was the result of the steady devotion of his genius, undistracted by pleasure or business, to his appointed task. For the first half of his life he prepared himself to be the great poet of his time and country with a high ambition and unresting industry, equalled only by the ambition and industry with which Cicero prepared himself to be the greatest orator and the most accomplished exponent of philosophy among his contemporaries and countrymen. The second half of his career was a religious consecration of all his powers of heart, mind, and spirit to his high office. He was born on the 19th of October[1] in the year 70 B.C., in a farm on the banks of the Mincio, in the district of Andes, not far from the town of Mantua. He thus belonged to a generation about thirty years younger than that to which Lucretius belonged, and about fifteen years younger than that of Catullus: but both these poets were dead before the younger poet was old enough or sufficiently known to have come into personal contact with them. But the literary impulse which gave birth to their poetry was felt in all its force in his early youth and especially in the district north of the Po, in which a race of more imaginative susceptibility than the people of Latium, who had been the first to receive the discipline and feel the enthusiasm of Greek studies, formed part of the Latin-speaking population.[2] It was favorable to his development as a national poet that he was born and educated during the interval of comparative calm between the first and second civil wars, and that he belonged to a generation which, as the result of the social war, first enjoyed the sense of an Italian nationality. Yet it was only after Virgil had grown to manhood that the province to which he belonged obtained the full rights of Roman citizenship. It is remarkable that the two poets whose imagination seems to have been most powerfully possessed by the spell of Rome,—Ennius and Virgil,—were born outside the pale of Roman citizenship, though belonging to races who had acknowledged the sovereignty without deeply or permanently resenting the hostility of Rome.

---

[1] [Prof. W. Y. Sellar, in *Roman Poets of the Augustan Age* (see *Bibliography* at end) adheres there to the 15th October as the date of Virgil's birth.—Am. Ed.]

[2] *Cf.* Cic., *Pro Archia*, iii. 5—"Erat Italia tunc plena Græcarum artium ac disciplinarum, studiaque hæc et in Latio vehementius tum colebantur quam nunc iisdem in oppidis, et hic Romæ propter tranquillitatem reipublicæ non neglegebantur."

The scenery familiar to his childhood, which he recalls with affection both in the *Eclogues* and the *Georgics*, was that of the green banks and slow windings of the Mincio and the rich pastures in its neighborhood. Like his friend and contemporary Horace, and unlike the poets of the preceding generation, who were members either of the aristocracy or of the class closely associated with it, he sprung from the class of yeomen, whose state he pronounces the happiest allotted to man and most conducive to virtue and piety. Virgil, as well as Horace, was fortunate in having a father who, though probably uneducated himself, discerned his genius and spared no pains in nourishing it with the highest and richest culture then obtainable in the world. At the age of twelve he was taken for his education to Cremona, an old Latin colony, and from an expression in one of the minor poems attributed to him, about the authenticity of which there cannot be any reasonable doubt, it may be inferred that his father accompanied him thither as Horace's father accompanied him to Rome for the same purpose. He assumed the *toga virilis* on his sixteenth birthday, the day, according to Donatus, on which Lucretius died; and shortly afterwards he removed to Milan, where he continued engaged in study till he went to Rome two years later. The time of his removal to Rome must have nearly coincided with the publication of the poem of Lucretius and of the collected poems of Catullus, the first really artistic poems produced in the Latin language. A powerful stimulus must have been given to a youth of genius from a northern province by his arrival in the metropolis of the world at such a crisis in the national literature. The impression produced on his imagination on his first coming to Rome may be recalled to memory in the lines he puts into the mouth of Tityrus in the first eclogue,

"Urbem quam dicunt Romam Melibœe putavi," etc.

After studying under a rhetorician, who was, probably about the same time, the teacher of the future emperor, he proceeded to the study of philosophy under Siron the Epicurean, who, in common with other teachers of that sect, appears to have had the gift of inspiring enthusiasm for his subject and affection for himself. One of the minor poems written about this time in the scazon metre, which had recently been brought to the highest possible perfection by Catullus, tells of his delight at the immediate prospect of entering on the study of philosophy, and of the first stirring of that enthusiasm for philosophical investigation which haunted him through the whole of his life, but never obtained complete realization. At the end of the poem, the real master-passion of his life, the charm of the Muses—"dulces ante omnia Musæ"—reasserts itself.

Our next knowledge of him is derived from allusions to his circumstances and state of feeling contained in the *Eclogues*, and belongs to a period nine or ten years later. Of what happened to him in the interval, during which the first civil war took place and Julius Cæsar was assassinated, we have no indication from ancient testimony or from his own writings. We might conjecture that this was a time of studious leisure passed in his father's house in the country, as the life of Milton was passed after leaving Cambridge. In 42 B.C., the year of the battle of Philippi, when he was in his 28th year, we find him leading such a life, "cultivating his woodland Muse," and enjoying the protection of Asinius Pollio, the governor of the district north of the Po. In the following year the famous confiscations of land for the benefit of the soldiers of the triumvirs took place. Of the impression produced on Virgil by these confiscations, and of the effect they had on his fortunes, we have a vivid record in the poem which stands first in his collected works. Mantua, in consequence of its vicinity to Cremona, which had been faithful to the cause of the republic, was involved in this calamity; and Virgil's father was driven from the farm which he had acquired by the thrift and industry of his early years. By the influence of his powerful friends, and by personal application to the young Octavianus, already practically master of the Western world, Virgil obtained the restitution of his land; but on attempting to resume possession of it, he was exposed to imminent personal danger, and had to swim across the river to escape from the violence of the soldier to whom it had been allotted. Immediately afterwards he took his father and family with him to the small country house of his old teacher Siron.

("Villula quæ Sironis eras, et pauper agelle," etc., *Catal.*, x.),

which may have become his own by gift or inheritance. Soon afterwards we hear of him living in Rome, enjoying, in addition to the patronage of Pollio, the favor of Mæcenas, intimate with Varius, who was at first regarded as the rising poet of the new era, and soon afterwards with Horace, who had just returned from his unfortunate adventure with the army of Brutus. His friendship with Gallus, for whom he indicates a warmer affection and more enthusiastic admiration than for any one else, was formed before his second residence in Rome, in the Cisalpine province, with which Gallus also was connected both by birth and office. The pastoral poems, or "eclogues," as they are usually called, though that name is never given to them by himself, commenced in his native district, were finished and published in Rome, probably in 37 B.C. Soon afterwards he withdrew from habitual residence in Rome, and lived chiefly in Campania, either at Naples or in a country house in the neighborhood of Nola. He resided also for some time in Sicily; and there is in the fourth *Georgic* distinct evidence of his familiarity with the neighborhood of Tarentum. He was one of the companions of Horace in the famous journey to Brundisium; and it seems not unlikely that, sometime before 23 B.C., he made the voyage to Athens which forms the subject of the third ode of the first book of the *Odes* of Horace.

The seven years from 37 to 30 B.C. were devoted to the composition of the *Georgics*. In the following year he read the poem to Augustus, on his return from Asia. The remaining years of his life were spent on the composition of the *Æneid*. In the course of its composition, in 23 B.C., the year of the death of the young Marcellus, he read three books, the 2d, 4th, and 6th, to the emperor and members of the imperial family. In 19 B.C., after the *Æneid* was finished but not finally corrected, he set out for Athens, intending to pass three years in Greece and Asia, and to devote that time to perfecting the workmanship of the poem. At Athens he met Augustus and was persuaded by him to return with him to Italy. While visiting Megara under a burning sun, he was seized with illness, and, as he continued his voyage without interruption, he grew rapidly worse, and died on the 21st of September, in his fifty-first year, a few days after landing at Brundisium. In his last illness he called for the cases containing his manuscripts, with the intention of burning the *Æneid*. He had previously left directions in his will that his literary executors, Varius and Tucca, should publish nothing of his which had not already been given to the world by himself. This pathetic desire that the work to which he had given so much care, and of which such great expectations were formed, should not survive him has been used as an argument to prove his own dissatisfaction with the poem. A passage from a letter of his to Augustus is also quoted, in which he speaks as if he felt that the undertaking of the work had been a mistake. Virgil does not indeed show that sanguine confidence in the result of his labors, which Horace expresses on the completion of the three books of lyrical poetry to which he devoted the best years of his life; but the lines (*Æn.*, ix. 444, etc.),

> "Fortunati ambo si quid mea carmina possunt," etc.,

though with less self-assertion, imply a similar assurance that his work would endure as long as the Roman state and empire. The dissatisfaction with his work, increased by the depression of his last illness and the fatigue of the long tension of mind, heart, and imagination upon it, may more probably be ascribed to his passionate craving for a perfection of workmanship which death prevented him from attaining than to any sense either of the unworthiness of his subject or of his own inadequacy to do justice to it. The commands of Augustus fortunately intervened to prevent the loss of some of the noblest poetry of antiquity and of the most enduring monument of the greatness and glory of Rome.

He was buried at Naples, where his tomb was long regarded with religious veneration, and visited as a temple. That veneration was a survival of the feeling with which he was regarded in his lifetime, and is greater than what we find attaching to the actual memory of any other ancient poet, though the mystery connected with the personality of Homer excited a greater curiosity. Horace is our most direct witness of the affection which he inspired among his contemporaries. The qualities by which he gained their love were, according to his testimony, "candor,"—that sincerity of nature and goodness of heart which, along with "fides" or loyalty, the Romans valued most among the qualities which attach men to one another; and "pietas,"—the deep affection for kindred, friends, and country, combined with a reverent spirit, which they prized above all personal qualities. The statement of his biographer, that he was known in Naples by the name "Parthenias," is a testimony to the exceptional purity of his life in an age of license. These direct testimonies are confirmed by the indirect testimony of his works. Scarcely any poet in any age seems to deserve so high a rank among those whom he himself characterizes as "pii vates et Phœbo digna locuti." The seclusion of his life and his devotion to his art touched the imagination of his countrymen as the finer qualities of his nature touched the heart of his friends. It has been, from the time of Cicero,[1] the ambition of the men of finest culture and most original genius in Rome to produce a national literature which might rival that of Greece; and the feeling that at last a poem was about to appear which would equal or surpass the greatest among all the works of Greek genius found a voice in the lines of Propertius—

> "Cedite Romani scriptores, cedite Graii;
> Nescio quid majus nascitur Iliade."

The feeling which his countrymen and contemporaries entertained towards him seems justified by the personal impression which he produces on modern readers,—an impression of sanctity, as of one who habitually lived in a higher and serener sphere than that of this world. The reverential love inspired by him is something distinct from the affection felt for Horace as a familiar friend, a wise counsellor, and genial companion, sharing the ordinary interests and pleasures of life, liable to the same weaknesses and endeared by the same social charm as those who are best liked in the intercourse of our own day.

Virgil's fame as a poet rests on the three acknowledged works of his early and mature manhood—the pastoral poems or *Eclogues*, the *Georgics*, and the *Æneid*—all written in that hexameter verse which he received from his immediate predecessors, still lacking something in variety and smoothness of cadence, and which he left to the world, in the words of a poet, who, if any one, is entitled to speak with authority on such a subject,

> "The noblest metre ever moulded by the lips of man."

But other poems were attributed to him in ancient times, and have been incorporated with his acknowledged works. These are (1) a collection of short poems, under the name "Catalepton," most of them in the style of the short poems of Catullus, and composed in various forms of the iambic metre (chiefly the scazon), and in elegiacs; and (2) some longer poems, the *Culex*, *Ciris*, *Copa*, *Moretum*, to which sometimes the *Ætna* and *Diræ* are added, all with one exception written in hexameters. As the younger Pliny mentions Virgil among the men of grave character by whose authority he justifies his own occasional indulgence in the composition of slight, playful, and somewhat indecorous verses, it is quite possible that two or three pieces of that kind found in the *Catalepton* may have been written by Virgil when fresh from the first reading of Catullus. The fifth, written in the couplet most used in the *Epodes* of Horace, and the most bitter in tone and coarsest in expression, it is impossible to attribute to him. But there are others among them of which there is no reason to question the authenticity, and which are interesting as an immediate expression of the poet's personal feelings at various periods of his life. Of the longer poems attributed to him in ancient times it is clear from internal evidence that the *Ciris* and *Diræ*, though belonging to the Augustan age, are not his. The *Ætna* has been shown to have been written in the age of Nero. The *Moretum* and the *Copa* are interesting as graphic and sharply defined pictures from common or homely life. But they have nothing in common with the idealizing art of Virgil, and the tone and sentiment of the *Copa* especially are quite alien from the tone and sentiment of his acknowledged work. But there has been more controversy about the authenticity of the *Culex*. The ambitious saying, not to apply to it a harsher epithet, attributed by his biographer to Lucan, "et quantum mihi restat ad Culicem," shows that in his time it was believed that Virgil had written a poem of that name. Martial (xiv. 185) writes of a *Culex* as the undoubted work of Virgil. He believes in it as unhesitatingly as he does in the "Passer Catulli," and speaks as if it were only the patronage of Mæcenas that enabled Virgil to rise to higher themes. Virgil's biographer speaks of the poem as having been written by him at the age of sixteen, though the saying of Lucan seems to imply that he supposed it to have been written when he was ten years older. The poem has no trace of the charm and variety of Virgil's style and rhythm, and is even less like the style and metre of the *Eclogues* than of his later poems. On the other hand, there is a technical correctness and regularity in the metre which was not possible until after the art of Virgil had made the knack of writing hexameters as attainable by all educated men as the art of Pope made the writing of the heroic couplet; and the writing of such verse seems to have become a regular part of a liberal education. It is to be remembered that in the same soil and under the same air under which the genius of Virgil and Horace expanded to such stately proportions, there was a great undergrowth of minor poets who are the frequent butts of Horace's good-natured satire. Descriptions of nature to which they were trained by the reading of Lucretius and Virgil, and mythological commonplace, were apparently the chief materials of their verse exercises. The descriptions in the *Culex* show the careful study both of Lucretius and of the *Eclogues* and *Georgics*, and, though too diffuse and diluted, are not without a real perception of, and feeling for, Italian nature. But it is very difficult to believe that the poem was ever edited by or acknowledged by Virgil in his lifetime. Nothing is more alien to his character than such immature ambition. It is difficult also to believe that it is a crude effort of his boyhood, accidentally preserved, and given to the world after his death by an authorized editor. It seems more probable that it is the composition of some young and enthusiastic admirer of Virgil, who, some time after his death, and, perhaps, after the death of his immediate contemporaries, succeeded in palming off his own imitative concoction as an early composition of the great master. The dedication to the "revered Octavius," if the

[1] *Cf. Tusc. Disp.*, ii. 2: "Quamobrem hortor omnes qui facere id possunt, ut hujus quoque generis laudem jam languenti Græciæ eripiant," etc. These words apply specially to philosophical literature, but other passages in the same and in other works imply that Cicero thought that the Romans had equal aptitudes for other departments of literature; and the practice of the Augustan poets in each appropriating to himself a special province of Greek literary art seems to indicate the same ambition.

person addressed is the "young Augustus," and not the poet and historian mentioned by Horace, and the lines—

> "Posterius graviore sono tibi musa loquetur
> Nostra, dabunt cum maturos mihi tempora fructus"—

seem like not very ingenious artifices to secure acceptance for the poem, and to represent Virgil as already in boyhood closely connected with the future emperor, and conscious of his own genius and of the great future that awaited both himself and the young friend whom he addresses as "sancte puer."

Eclogues.

The pastoral poems or *Eclogues*—a word denoting short selected pieces—were composed between the years 42 and 37 B.C., when Virgil was between the age of twenty-eight and thirty-three. By his invocation to the "Sicelides Musæ" and "Arethusa," by the names "Daphnis" and "Menalcas," "Thyrsis" and "Corydon," etc., which he gives to his shepherds, by his mention of "Arcadians" and of "Eurotas," and by many other indications, he avows the purpose of eliciting from the strong Latin language the melody which the "Sicilian shepherd" drew out of the "Doric reed," of peopling the familiar plains and river-banks of his native land with the picturesque figures of the old Greek pastoral, and of expressing that tender feeling for the beauty of Italian scenes which Theocritus had expressed for the beauty of Sicily. The position of Virgil indicated in the *Eclogues* was not unlike that indicated in the idyls of Theocritus,—that of a youth of genius with all the refinement of a rich culture, but with rustic tastes and habits, living his life among other young poets of his native province, cultivating his art by friendly rivalry with them, and nourishing his genius by communion with the spirit of nature as revealed in the scenes around him and in the melodies of older poets. It was as natural under these circumstances that he should aspire to be the Italian Theocritus as that Horace, with his more social and versatile temperament, and with the more adventurous experience of his youth, should aspire to be the Roman Alcæus.

The earliest poems in the series were the second, third, and fifth; and these, along with the seventh, are the most purely Theocritean in character. The first and ninth, which probably were next in order, are much more Italian in sentiment, are much more an expression of the poet's own feelings, and have a much more direct reference both to his own circumstances and the circumstances of the time. The first is a true poetical reflex of the distress and confusion which arose out of the new distribution of lands, and blends the poet's own deep love of his home, and of the sights and sounds familiar to him from childhood, with his Italian susceptibility to the beauty of nature. The ninth is immediately connected in subject with the first. It contains the lines which seem accurately to describe the site of Virgil's farm, at the point where the range of hills which accompany the river for some distance from the foot of the Lago di Garda sinks into the plain about 14 or 15 miles above Mantua—

> "Qua se subducere colles
> Incipiunt mollique jugum demittere clivo."

The sixth is addressed to Varus, who succeeded Pollio as governor of the Cisalpine district. Its theme is the creation of the world (according to the Epicurean cosmogony), and the oldest tales of mythology.[1] The fourth and eighth are both closely associated with the name of Virgil's earliest protector, Pollio. The fourth celebrates the consulship of his patron in 40 B.C., and perhaps also the birth of his son, though it was disputed in antiquity, and still is disputed, who was meant by the child whose birth was to be coincident with the advent of the new era, and who, after filling the other great offices of state, was to "rule with his father's virtues the world at peace." The main purpose of the poem, however, is to express, in connection with pastoral associations, the longing of the world for a new era of peace and happiness, of which the treaty of Brundisium seemed to hold out some definite hopes. There is no trace in this poem of Theocritean influence. The rhythm recalls the stately monotonous movement of the longest poem of Catullus, not the vivacity of the idyllic rhythm. The ideas are derived partly from Greek representations of the Golden Age, and partly, it is supposed, from the later Sibylline prophecies, circulated after the burning in the time of Sulla of the old Sibylline books, and possibly tinged with Jewish ideas. Some of the phraseology of the poem led to a belief in the early Christian church that Virgil had been an unconscious instrument of inspired prophecy. The date of the eighth is fixed by a reference to the campaign of Pollio against the Dalmatians in 39 B.C. It is founded on the *Φαρμακευτρία* of Theocritus, but brings before us, with Italian associations, two love tales of homely Italian life. The tenth reproduces the Daphnis of Theocritus, and is a dirge over the unhappy love of Gallus and Lycoris. As in the other poems, the second and eighth, of which love is the burden, it is to the romantic and fantastic melancholy which the passion assumes in certain natures that Virgil gives a voice. Nothing can be more unreal than the association of such a feeling with an ordinary *liaison* like that of Gallus, the adventurous and ambitious soldier, and Cytheris, the notorious actress and discarded mistress of Antony. But there is no representation in ancient poetry of an ideal and chivalrous passion so tender and true as that of the Gallus of Virgil.

There is no important work in Latin literature, with the exception of the comedy of Terence, so imitative as the *Eclogues*. But they are not, like the comedies of Terence, purely exotic as well as imitative. They are rather composite, partly Greek and partly Italian, and, as a vehicle for the expression of feeling, hold an undefined place between the objectivity of the Greek idyl and the subjectivity of the Latin elegy. For the most part, they express the sentiment inspired by the beauty of the world, and the kindred sentiment inspired by the charm of human relationships. Virgil's susceptibility to the beauty of nature was fostered by the sympathetic study of Theocritus, but it was also native to himself. The originality of his representation appears in the truth with which it suggests the charm of Italy—the fresh and tender life of an Italian spring, the grace and delicate hues of the wild flowers, and the quiet beauty of the green pastures and the rich orchards of his native district. The representative character of the poems is enhanced by the fidelity and grace with which he has expressed the Italian peasant's love of his home and of all things associated with it. But, whatever detraction may have to be made from the originality of the substance and form of these poems, the supreme charm of the medium of diction and rhythm through which the poet's feeling has found utterance is universally recognized. The power of varied harmony is as conspicuous in Virgil's earliest poems as in the maturer and more elaborate workmanship of the *Georgics* and *Æneid*. The Italian language, without sacrifice of the fulness, strength, and majesty of its tones, acquired a more tender grace and more liquid flow, which reappeared long after in the poets of modern Italy, from the gift—the "molle atque facetum"—which the Muses of country life bestowed on Virgil.

Georgics.

But these Muses had a more serious and dignified function to fulfil than that of glorifying the picturesque pastime, the "dolce far niente," the "otia dia," of rural life. The Italian imagination formed an ideal of the happiness of a country life nobler than that of passive susceptibility to the lights and sounds of the outward world. In the idyllic picture in which Horace enumerates the various delights of the countryman's condition (*Epode* 2), while the pleasures to eye and ear are not wanting, more stress is laid on the labors by which man co-operates with nature, and on the joy with which he contemplates the results of his toil. It was the aim of the more serious Roman writers to invest objects which minister to practical utility with the glory and charm of poetry. Suetonius tells us that Augustus valued nothing so much in literature as "præcepta et exempla publice, vel privatim salubria." It is stated that Mæcenas, acting on the principle of employing the poets of the time in favor of the conservative and restorative policy of the new government, directed the genius of Virgil to the subject of the *Georgics*. From a moral, social, and national point of view, no object could be of more consequence in the eyes of a statesman whose master inherited the policy of the popular leaders than the revival of the great form of national industry, associated with the older and happier memories of Rome, which had fallen into abeyance owing to the long unsettlement of the revolutionary era as well as to other causes. Virgil's previous life and associations made it natural for him to identify himself with this object, while his genius and artistic accomplishment fitted him to enlist the imagination of his countrymen in favor of so great a practical reform. It would be a most inadequate and false view of his purpose to suppose that, like the Alexandrian poets or the didactic poets of modern times, he desired merely to make useful information and practical precepts more attractive by the aid of poetical rhythm and diction. His aim was rather under the form of practical instruction to describe with realistic fidelity, and at the same time to surround with an atmosphere of idealizing poetry, the annual round of labor in which the Italian yeoman's life was passed; to bring out the intimate relation with the manifold aspects and processes of nature into which man was brought in the course of that life and to suggest the delight to heart and imagination which he drew from it; to contrast the simplicity, security, and sanctity of such a life with the luxury and lawless passions of the great world; and to associate the ideal of a life of rustic labor with the varied beauties of Italy and the historic glories of Rome. Thus a speculative and religious, an ethical and patriotic, motive enlarges and supersedes the apparent motive of conveying instruction. This larger conception of the dignity of his subject separates the didactic poem of Virgil from all other didactic, as distinct from philosophic, poems. He has produced in the *Georgics* a new type of didactic, as in the *Æneid* he has produced a new type of epic, poetry.

---

[1] In the *Georgics* also Virgil attempts to combine science with the poetic fancies which filled its place in older times.

The subject which is unfolded in the four opening lines—

> " Quid faciat lætas segetes, quo sidere terram
> Vertere, Mæcenas, ulmisque adjungere vites
> Conveniat; quæ cura boum, qui cultus habendo
> Sit pecori, apibus quanta experientia parcis"—

is treated in four books, varying in length from 514 to 566 lines. The first treats of the tillage of the fields, of the constellations, the rise and setting of which form the farmer's calendar, and of the signs of the weather, on which the success of his labors largely depends. The second treats of the cultivation of trees, and especially of the vine and olive, two great staples of the national wealth and industry of Italy; the third of the rearing of herds and flocks and the breeding of horses; the fourth of the tending of bees. The treatment of these homely subjects is relieved by various episodes, introduced at various places, but mainly at the end of the different books, which serve to bring out the intimate connection of his theme with his national and ethical purpose.

As he had found in Theocritus a model for the form in which his idler fancies were expressed, he turned to an older page in Greek literature for the outline of the form in which his graver interest in rural affairs was to find its outlet; and, though the *Works and Days* of Hesiod could not supply an adequate mould for the systematic treatment of all the processes of rural industry, and still less for the treatment of the larger ideas to which this systematic treatment of the subject is subsidiary, yet that Virgil considered him as his prototype is shown by the line which concludes one of the cardinal episodes of the poem—

> " Ascræumque cano Romana per oppida carmen."

By the use which he makes of his quaint phraseology Virgil attracts attention to the relation which he wishes to establish between himself and Hesiod; and in the religious spirit with which they each regard man's labors and condition in the world there is a real affinity between the primitive Bœotian bard and the refined artist of the Augustan age. Virgil accepts also the guidance of other models of the decadence of Greek literature, the Alexandrian poets who treated the science of their day—astronomy, natural history, and geography—in the metre and diction of epic poetry. But, in availing himself of the work of the Alexandrians, Virgil is like a great master making use of mechanical assistants. From the comparison of passages in the *Georgics* with passages in those authors which suggested them, we learn to appreciate the immeasurable superiority of the poetical language of Rome at the maturity of its development over the exotic diction produced in the decay of Greek creative imagination. But a more powerful influence on the form, ideas, sentiment, and diction of the *Georgics* was exercised by the great philosophical poem of Lucretius, of which Virgil had probably been a diligent student since the time of its first appearance, and with which, in the phrase of the English editor of the older poet, his mind was " saturated " when he was engaged in the composition of the *Georgics*. In Virgil we find the spirit of Hesiod in conflict with the spirit of Lucretius. He is at once attracted and repelled by the genius and attitude of the philosophic poet. He is possessed by his imaginative conception of nature, as a living all-pervading power; he shares with him the Italian love of the beauty of the world, and the pathetic sympathy with animal as well as human life. He recognizes with enthusiasm his contemplative elevation above the petty interests and passions of life. But he is repelled by his apparent separation from the ordinary beliefs and pleasures, the hopes and fears, of his fellow-men. Virgil is in thorough sympathy with the best restorative tendencies—religious, social, and national—of his time; Lucretius was driven into isolation by the anarchic and dissolving forces of his.

So far as any speculative idea underlying the details of the *Georgics* can be detected, it is one of which the source can be traced to Lucretius—the idea of the struggle of human force with the forces of nature. In Virgil this idea is modified by Italian piety and by the Italian delight in the results of labor. In the general plan of the poem, and the systematic arrangement of his materials, Virgil follows the guidance of Lucretius rather than of any Greek model. The dedication and personal appeals to Mæcenas are parallel to those addressed to Memmius. The distinction between a poem addressed to national and one addressed to philosophical sympathies is marked by the prominence assigned in the one poem to Cæsar as the supreme personality of the age, in the other to Epicurus as the supreme master in the realms of mind. The invocation to the " Di agrestes," to the old gods of mythology and art, to the living Cæsar as the latest power added to the pagan Pantheon, is both a parallel and a contrast to the invocation to the all-pervading principle of life, personified as " Alma Venus." In the systematic treatment of his materials, and the interspersion of episodes dealing with the deeper poetical and human interest of the subject, Virgil adheres to the practice of the older poet. He makes use of his connecting links and formulas, such as " principio," " quod superest," " his animadversis," " nunc age," etc. Virgil indeed uses these more sparingly, so as to make the logical mechanism of the poem less rigid, while he still keeps up the liveliness of a personal address. He shows his artistic superiority by passing lightly over details which it is impossible to invest with beauty. All his topics admit of being vitalized by attributing the vivacity of human relationships and sensibility to natural processes, and by association with the joy which the ideal farmer feels in the results of his energy. Much of the argument of Lucretius, on the other hand, is as remote from the genial presence of nature as from human associations. Virgil makes a much larger use than Lucretius of ornament borrowed from older poetry, art, science, and mythology. There is uniformity of chastened excellence in the diction and versification of the *Georgics*, contrasting with the imaginative force of isolated expressions and the majesty of isolated lines and passages in Lucretius. The " vivida vis " of imagination is more apparent in the older poet; the artistic perfection of Virgil is even more conspicuous in the *Georgics* than in the *Eclogues* or the *Æneid*.

The principal episodes of the poem, in which the true dignity and human interest of the subject are brought out, occur in the first and second books. Other shorter episodes interspersed through the different books add variety to the didactic disquisition. These episodes, as is the case still more with the episodes of Lucretius, are not detached or isolated ornaments, but give a higher unity to the poem, and are the main ground of its permanent hold upon the world. There is indeed one marked exception to this rule. The long episode with which the whole poem ends,—the tale of the shepherd Aristæus, with which is connected the more poetical fable of Orpheus and Eurydice, has only the slightest connection with the general ideas and sentiment of the poem. It is altogether at variance with the truthful realism and Italian feeling which prevade it. If we suppose that Virgil originally thought it necessary to relieve the interest and keep the attention of his readers by appealing to their taste for those mythological tales, which in an earlier part of the poem he had decried as " omnia jam volgata," it would be difficult to acquit even so great an artist of some forgetfulness of the requirement of unity of impression in a work of art, especially in such a " templum de marmore " as the *Georgics*. But we are distinctly told that the concluding episode, from the middle till the end of the fourth book, had contained the praises of Gallus, the friend of Virgil's youth, who, about the time when Virgil was finishing the poem, had gained distinction in the war against Cleopatra, and had in consequence been made the first governor of the new province of Egypt. It is difficult to see how such a statement could have been invented if it were not true. Such a conclusion might well have been in keeping with the main purpose of the poem. As the first book ends with a dirge over the national fortunes before the outbreak of the war with Antony and Cleopatra, the last book might well have ended with a hymn of triumph over the successful end of that war, in which the hero of Virgil's youthful enthusiasm played so distinguished a part. After the fall of Gallus, owing to his ambitious failure in his Egyptain administration, and his death in 26 B.C., the poet, according to the story, in obedience to the command of the emperor, substituted for this encomium the beautiful but irrelevant fable of Orpheus and Eurydice, in which he first displayed the narrative skill, the pathos, and the magical power of making the mystery of the unseen world present to the imagination, which characterize the *Æneid*.

The cardinal episodes of the poem, as it now stands, are the passages in bk. i. from line 464 to the end, and in bk. ii. from 136 to 176 and from 475 to 542. The first, introduced in connection with the signs of the weather, recounts the omens which accompanied the death of Julius Cæsar, and shows how the misery of Italy and the neglected state of the fields, for which the poem seeks to find a remedy, are the punishment for the great sin of the previous generation. In the second of these passages the true keynote of the poem is struck in the invocation to Italy—

> "Salve, magna parens frugum, Saturnia tellus,
> Magna virum."

The thought of the varied beauties of the land, of the abundance and variety of its products, of its ancient cities and mighty works of man, its brave and hardy races, the great men and great families who had fought for her and saved her in old times, and of him, the greatest among her sons, who was then defending Rome against her enemies in the farthest East, inspires the poet, and gives dignity to the trivial details which seem sometimes to clog his high ambition. But a still higher and more catholic interest is given to the subject in the greatest of the episodes,—the most perfect passage in all Latin poetry,—that from line 458, "O fortunatos nimium," to the end. The subject is there glorified by its connection not only with the national wellbeing but with the highest life and purest happiness of man. An ideal is held up to the imagination in which the old realistic delight in the labors of the field blends with the new delight in the beauty of nature, and is associated with that purity and happiness of family life which was an Italian ideal, and with the poetry of those religious beliefs and observances which imparted a sense of security, a constantly recurring charm, and a bond of social sympathy to the old rustic life.

The *Georgics* is not only the most perfect in art, but is the most native in sentiment and conception of all the works of the ancient Italian genius. It is essentially Italian in idea, in detail, in religious and ethical feeling, in coloring and sentiment, in its solid and massive composition. Though the form was borrowed from the Greek, yet we have to remember that it was only by becoming a province of Roman art that the didactic poem acquired dignity and the capacity of treating a great theme. Even where he borrows from Greek originals, Virgil, like a conqueror makes the Greek mind tributary to his national design. The *Georgics*, the poem of the land, is as essentially Italian as the *Odyssey*, the poem of the sea, is essentially Greek. Nature is presented to us as she is revealed in the soft and rich luxuriance of Italian landscape, not in the clearly defined forms of Greek scenery. The ethical and religious ideal upheld is an Italian one. As a work of art, while showing in the largest degree the receptivity of the Greek feeling for form and symmetry which was the primary condition of all Roman success in literature, the poem shows equally the Italian susceptibility to the beauty of the outward world, the dignity and sobriety of the Italian imagination, the firm and enduring structure of all Roman workmanship.

Æneid.

The work which yet remained for Virgil to accomplish was the addition of a great Roman epic to literature. This had been the earliest effort of the national imagination, when it first departed from the mere imitative reproduction of Greek originals. The work which had given the truest expression to the genius of Rome before the time of Virgil had been the *Annales* of Ennius. This work had been supplemented by various historical poems but had never been superseded. It satisfied the national imagination as an expression of the national life in its vigorous prime, but it could not satisfy the newly developed sense of art; and the expansion of the national life since the days of Ennius, and the changed conditions into which it passed after the battle of Actium, demanded a new and ampler expression. It had been, as we learn both from his biographer and from himself—

> 'Cum canerem reges et prœlia"—

Virgil's earliest ambition to write an heroic poem founded on the traditions of Alba Longa; and he had been repeatedly urged by Augustus to celebrate his exploits. The problem before him was to compose a work of art on a large scale, which should represent a great action of the heroic age, and should at the same time embody the most vital ideas and sentiment of the hour,—which in substance should glorify Rome and the present ruler of Rome, while in form it should follow closely the great models of epic poetry and reproduce all their sources of interest. It was his ambition to be the Homer as he had been the Theocritus and Hesiod of his country.

Various objects had thus to be combined in a work of art on the model of the Greek epic: the revival of interest in the heroic foretime; the satisfaction of the national and imperial sentiment; the expression of the enthusiasm and of the deeper currents of emotion of the age; the personal celebration of Augustus. A new type of epic poetry had to be created, as a new type of didactic poetry had been realized in the *Georgics*. It was desirable to select a single heroic action which should belong to the cycle of legendary events celebrated in the Homeric poems, and which should be associated with the whole fortunes of Rome and with the supreme interests of the hour. The only subject which in any way satisfied these apparently irreconcilable conditions was that of the wanderings of Æneas and of his final settlement in Latium. The story, though not of Roman origin but of a composite growth, had been familiar to the Romans from the beginning of their literature, and had been recognized by official acts of senate and people as associated with the national fortunes. The subject enabled Virgil to tell over again and to give novelty to the tale of the fall of Troy, and to tell a tale of sea-adventure similar to that of the wanderings of Odysseus. But the special applicability of his subject to his purpose was determined by the claim which the Julii, a patrician family of Alban origin, made to descent from Iulus, the supposed son of Æneas and founder of Alba Longa. The personal, as distinct from the national and artistic, motives of the poem could be satisfied by this subject alone.

The *Æneid* is thus at once the epic of the national life under its new conditions and an imitative epic of human actions, manners, and character. The true keynote of the poem is struck in the line with which the poem closes—

> "Tantæ molis erat Romanam condere gentem."

The idea which underlies the whole action of the poem is that of the great part played by Rome in the history of the world, that part being from of old determined by divine decree, and carried out through the virtue of her sons. The idea of universal empire is thus the dominant idea of the poem. With this idea that of the unbroken continuity of the national life is intimately associated. The reverence for antiquity, for old customs and the traditions of the past, was a large element in the national sentiment, and has a prominent place in the *Æneid*. So too has the feeling of local attachment and of the power of local association over the imagination. This feeling is especially appealed to in the eighth book, which has been called the most purely Roman in the poem. The poem is also characteristically Roman in the religious belief and observances which it embodies. Behind all the conventional and artistic machinery of the old Olympic gods there is the Roman apprehension of a great inscrutable power, manifesting itself by arbitrary signs, exacting jealously certain observances, alienated for a time by neglect, and again appeased by compliance with its will, working out its own secret purposes through the agency of Roman arms and Roman counsels.

The word by which Virgil recognizes this power is Fatum (or Fata in the plural). The hero of the *Æneid* is an instrument in their hands, and the living emperor is regarded as fulfilling the same function in the actual world. The predominance of this idea gives coherence to the action, and establishes its relation to the whole national life. The poem is thus a religious as well as a national epic, and this explains the large part played in the development of the action by special revelation, omens, prophecies, ceremonial usages, and prayer. But, while the predominant religious idea of the poem is that of a divine purpose carried out regardlessly of human feeling, in other parts of the poem, and especially in that passage of the sixth book in which Virgil tries to formulate his deepest convictions on individual destiny, the agency of fate seems to yield to that of a spiritual dispensation, awarding to men their portions according to their actions.

The idealization of Augustus is no expression of servile adulation. It is through the prominence assigned to him that the poem is truly representative of the critical epoch in human affairs at which it was written. The cardinal fact of that epoch was the substitution of personal rule for the rule of the old commonwealth over the Roman world. Virgil shows the imaginative significance of that fact by revealing the emperor as chosen from of old in the counsels of the supreme ruler of the world to fulfil the national destiny, as the descendant of gods and of heroes of old poetic renown, as one, moreover, who, in the actual work done by him, as victor in a great decisive battle between the forces of the Western and the Eastern world, as the organizer of empire and restorer of peace, order, and religion, had rendered better service to mankind than any one of the heroes who in an older time had been raised for their great deeds to the company of the gods.

Virgil's true and yet idealizing interpretation of the imperial idea of Rome, in its national, religious, and personal significance, is the basis of the monumental greatness of the *Æneid* as a representative poem. It is on this representative character and on the excellence of its artistic execution that the claim of the *Æneid* to rank as one of the great poems of the world mainly rests. The inferiority of the poem to the *Iliad* and the *Odyssey* as a direct representation of human life is so unquestionable that we are in greater danger of underrating than of overrating the real though secondary interest which the poem possesses as an imitative epic of human action, manners, and character. What are the main sources of human interest in the poem can only be briefly indicated. In the first place, the action is chosen not only as suited to embody the idea of Rome and the dominant sentiment of a great and critical epoch in human affairs, but as having a peculiar nobleness and dignity of its own. It brings before us the spectacle, but restored by the light of a romantic imagination cast upon dim traditions, of the destruction of the city of greatest name in poetry or legend, the supposed seat of a prehistoric empire, of the foundation of the imperial city of the Western seas, in which Rome had encountered her most powerful and dangerous antagonist in the whole course of her long struggle for supremacy, and that of the first rude settlement on the hills of Rome itself. The scenes through which the action is carried are familiar, yet full of great memories and associations,—Troy and its neighborhood, the seas and islands of Greece, the coasts of Epirus, familiar to all travellers between Italy and the East, Sicily, the site of Carthage, Campania, Latium, the Tiber, and all the country within sight of Rome. The personages of the action are prominent in poetry and legend, or by their ethnical names stir the sentiment of national enthusiasm, —Æneas and Anchises, Dido, Acestes, Evander, Turnus. The spheres of activity in which they are engaged are war and sea-adventure, the themes of the oldest and greatest of epic poems. The passion of love, which had played a great part in Attic tragedy and in the epic and elegiac poets of Alexandria, is a powerful addition to the older sources of interest which Virgil derives from the Homeric poems. The *Æneid*, like the Alexandrian epic, revives, by a conventional compromise between the present and the remote past, some image of the old romance of Greece; it creates the romance of "that Italy for which Camilla the virgin, Euryalus, and Turnus and Nisus died of wounds." It might be said of the manner of life represented in the *Æneid*, that it is no more true to any actual condition of human society than that represented in the *Eclogues*. But may not the same be said of all idealizing restoration of a remote past in an age of advanced civilization? The life represented in the *Œdipus Tyrannus* or in *King Lear* is not the life of the Periclean nor of the Elizabethan age, nor is it conceivable as the real life of a prehistoric age. The truth of such a representation is to be judged, not by its relation to any actual state of things ever realized in the world, but by its relation to an ideal of the imagination,—the ideal conception of how man, endowed with the gifts and graces of a civilized time, but who had not yet lost the youthful buoyancy of a more primitive age, might play his part under circumstances which would afford scope for the passions and activities of a vigorous personality, and for the refined emotions and subtle reflection of an era of high intellectual and moral cultivation. The verdict of most readers of the *Æneid* will be that Virgil does not satisfy this condition, as it is satisfied by Sophocles and Shakespeare. Yet there is a considerable attraction in the compromise which Virgil has produced between the life which he knew by experience and that which he saw in the past of his imagination. There is a courtesy, dignity, and consideration for the feelings of others in the manners of his chief personages, such as might be exhibited by the noblest and most commanding natures in an age of chivalry and in an age of culture. The charm of primitive simplicity is present in some passages of the *Æneid*, the spell of luxurious pomp in others. The actual delight of voyaging past beautiful islands, familiar to travellers in the Augustan age, is enhanced by the suggestion of the adventurous spirit which sent the first explorers abroad in search of unknown settlements. Where Virgil is least real, and least successfully ideal, and where consequently he is most purely imitative, is in the battle-scenes of the later books. They afford scope, however, to his patriotic desire to do justice to the martial energy of the Italian races; and some of them have a peculiar beauty from the pathos with which the death of some of the more interesting personages of his story is described.

But the adverse criticisms of the *Æneid* are chiefly based on Virgil's supposed failure in the crucial test of a great poem of action, the creation of character. And his chief failure is pronounced to be in the protagonist of the poem, the "pious Æneas." Is this charge true? Is Æneas a worthy and interesting hero of a great poem of action? Not, certainly, according to the ideals realized in Achilles and Odysseus, nor according to the modern ideal of gallant and adventurous heroism. A blameless character, patiently enduring much suffering, cannot arouse the same personal interest as a more energetic and impulsive character, relying on his own resources, and stirred by ordinary human passions. It is well said of Æneas by a French critic—"Sa vertu doit être une haute et froide impersonalité, qui fasse de lui non un homme mais un instrument des dieux." Virgil wishes to hold up in Æneas an ideal of pious obedience, steadfast endurance, persistent purpose,—a religious ideal belonging to the ages of faith combined with the humane and self-sacrificing qualities belonging to an era of moral enlightenment. The virtues of the natural man—chivalry and daring courage—he represents in Turnus. His own sympathy is with his religious ideal rather than with that which better satisfies modern sentiment, nursed on the traditions of chivalrous romance. Yet that there was in his own imagination, more than in that of any other Roman writer, a chord responsive to the chivalrous emotion of a later time is seen in the love and pathos which he has thrown into his delineations of Pallas, Lausus, and Camilla. But, with all his sympathies with the "Itala virtus"—the martial virtues of the old Italian race and the martial prowess of Rome,—he felt that the deepest need of his time was not military glory, but peace, reconciliation, the restoration of law, order, and piety.

Among the personages of the *Æneid* the only one which entitles Virgil to rank among great creators is Dido, an ideal of a true queen and a true woman. She is the sole creation which Roman poetry has added to the great gallery of men and women filled by the imaginative art of different times and peoples. There are the outlines of a great creation in Mezentius; but Dido alone is a life-like and completed picture. On the episode of which she is the heroine the most passionate human interest is concentrated. It has been objected that Virgil does not really sympathize with his own creation, that he gives his approval to the cold desertion of her by her "false friend." Whether he sympathizes with his own creation or not, he is entirely possessed by it. If he does not condemn his hero, he sees in the desertion and death of Dido a great tragic issue in which a noble and generous nature is sacrificed to the larger purpose of the gods. But that Virgil really sympathized with the creation of his imagination appears, not only in the sympathy which she still inspires, but in the part which he assigns to her in that shadowy realm in which he conceives that the "world's great wrongs" are at last righted—

> "Conjunx ubi pristinus illi
> Respondet curis, æquatque Sychæus amorem."

Even those who have been insensible to the representative and to the human interest of the *Æneid* have generally recognized the artistic excellence of the poem. This is conspicuous both in the conception of the action and the arrangement of its successive stages and in the workmanship of details. In variety of interest and finish of execution the first eight books are superior to the last four. Each of the former has a large and distinct sphere of interest, and they each contribute to the impression of the work as a whole. In the first book we have the interest of the storm, of the prophecy of Jove, and of the building of Carthage; in the second the spectacle of the destruction of Troy; in the third the voyage among the islands and coasts of the Mediterranean; in the fourth the tragedy of Dido; in the fifth the rest in the Sicilian bay, at the foot of Mount Eryx; in the sixth the revelation of the spiritual world of Virgil's imagination, and of the souls of those who built up the greatness of Rome in their pre-existent state, in their shadowy dwelling-place; in the seventh the arrival of the Trojans at the mouth of the Tiber and the gathering of the Italian clans; in the eighth the first sight of the hills of Rome, and the prophetic representation of the great crises in Roman history, leading up to the greatest of them all, the crowning victory of Actium. Among these books we may infer that Virgil assigned the palm to the second, the fourth, and the sixth, as he selected them to read to Augustus and the members of the imperial family. The interest flags in the last four; nor is it possible to feel that culminating sympathy with the final combat between Turnus and Æneas that we feel with the combat between Hector and Achilles. Yet a personal interest is awakened in the adventures and fate of Pallas, Lausus, and Camilla. Virgil may himself have become weary of the succession of battle-scenes—"eadem horrida bella,"—which the requirements of epic poetry rather than the impulses of his own genius or the taste of his readers called upon him to portray; and this may partly account for the sense of discouragement which he is supposed to have felt at the end of his labors. There is not only a less varied interest, there is greater inequality of workmanship in the later books, owing to the fact that they had not received their author's final revisal. Yet in them there are many lines and passages of great power, pathos, and beauty. Virgil brought the two great instruments of varied and continuous harmony and of a rich, chastened, and noble style to the highest perfection of which the Latin tongue was capable. The rhythm and style of the *Æneid* is more unequal than the rhythm and style of the *Georgics*, but is a larger and more varied instrument. The note of his supremacy among all the poetic artists of his country is that subtle fusion of the music and the meaning of language which touches the deepest and most secret springs of emotion. He touches especially the emotions of reverence and of a yearning for a higher spiritual life, and the sense of nobleness in human affairs, in great institutions, and great natures; the sense of the sanctity of human affections, of the imaginative spell exercised by the past, of the mystery of the unseen world. This is the secret of the power which his words have had over some of the deepest and greatest natures both in the ages of faith and in more positive times. No words more subtly and truly express the magic of his style than those in which Dr. Newman characterizes "his single words and phrases, his pathetic half-lines, giving utterance as the voice of nature herself to that pain and weariness, yet hope of better things, which is the experience of her children in every age."

The most important of the recent editions of Virgil are those of Heyne and the revised edition by Wagner, that of Forbiger, of Ribbeck, of E. Benoist, and of Conington. Among recent works bearing on the literary criticism of Virgil are Sainte-Beuve's *Étude sur Virgile*, M. G. Boissier's *La Religion Romaine d'Auguste aux Antonins*, Comparetti's *Virgilio nel Medio Evo*, *Vergil und die epische Kunst*, by Theodor Plüss, various works by Prof. Nettleship, and Prof. Sellar's *Roman Poets of the Augustan Age*. The best critical estimate of the genius and art of Virgil in English is that of Mr. F. Myers. Among recent translations of the *Æneid* are those of Conington, Mr. W. Morris, and Lord Justice Bowen in verse, and of Conington and Mr. J. W. Mackail in prose. (W. Y. S.)

VIRGIL, POLYDORE (*c.* 1470–1555), author of the *Historia Anglica*, otherwise known as P. V. CASTELLENSIS, was a kinsman of Cardinal Hadrian Castellensis, a native of Castro in Etruria. His father's name is said to have been George Virgil; his great-grandfather, Anthony Virgil, "a man skilled in medicine and astrology," had professed philosophy at Paris, as did Polydore's own brother and protégé, John Matthew Virgil, at Pavia, in 1517. A third brother was a London merchant in 1511. Polydore is said to have been educated at Bologna, and was probably in the service of Guido Ubaldo, duke of Urbino, before 1498, as in the dedication of his first work, *Liber Proverbiorum* (April, 1498), he styles himself this prince's client. Polydore's second book, *De Inventoribus Rerum*, is dedicated to Guido's tutor, Ludovicus Odaxius, from Urbino, in August, 1499. After being chamberlain to Alexander VI. he came to England in 1501 as deputy collector of Peter's pence for the cardinal. As Hadrian's proxy, he was enthroned bishop of Bath and Wells in October, 1504. It was at Henry VII.'s instance that he commenced his *Historia Anglica*—a work which, though seemingly begun as early as 1505, was not completed till August, 1533, the date of its dedication to Henry VIII., nor published till 1534. In May, 1514, he and his patron the cardinal are found supporting Wolsey's claims to the cardinalship, but he had lost the great minister's favor before the year was out. A rash letter, reflecting severely on Henry VIII. and Wolsey, was intercepted early in 1515, after which Polydore was cast into prison and supplanted in his collectorship (March and April). He was not without some powerful supporters, as both Catherine de' Medici and Leo X. wrote to the king on his behalf. From his prison he sent an abject and almost blasphemous letter to the offended minister, begging that the fast approaching Christmas—a time which witnessed the restitution of a world—might see his pardon also. He was set at liberty before Christmas, 1515, though he never regained his collectorship. In 1525 he published the first edition of Gildas, dedicating the work to Tunstall, bishop of London. Next year appeared his *Liber de Prodigiis*, dedicated from London (July) to Francesco Maria, duke of Urbino. Somewhere about 1538 he left England, and remained in Italy for some time. Ill-health, he tells us, forbade him on his return to continue his custom of making daily notes on contemporary events. About the end of 1551 he went home to Urbino, where he appears to have died in 1555. He had been naturalized in October, 1510, and had held several clerical appointments in England. In 1508 he was appointed archdeacon of Wells, and in 1513 prebendary of Oxgate in St. Paul's Cathedral, both of which offices he held after his return to Urbino.

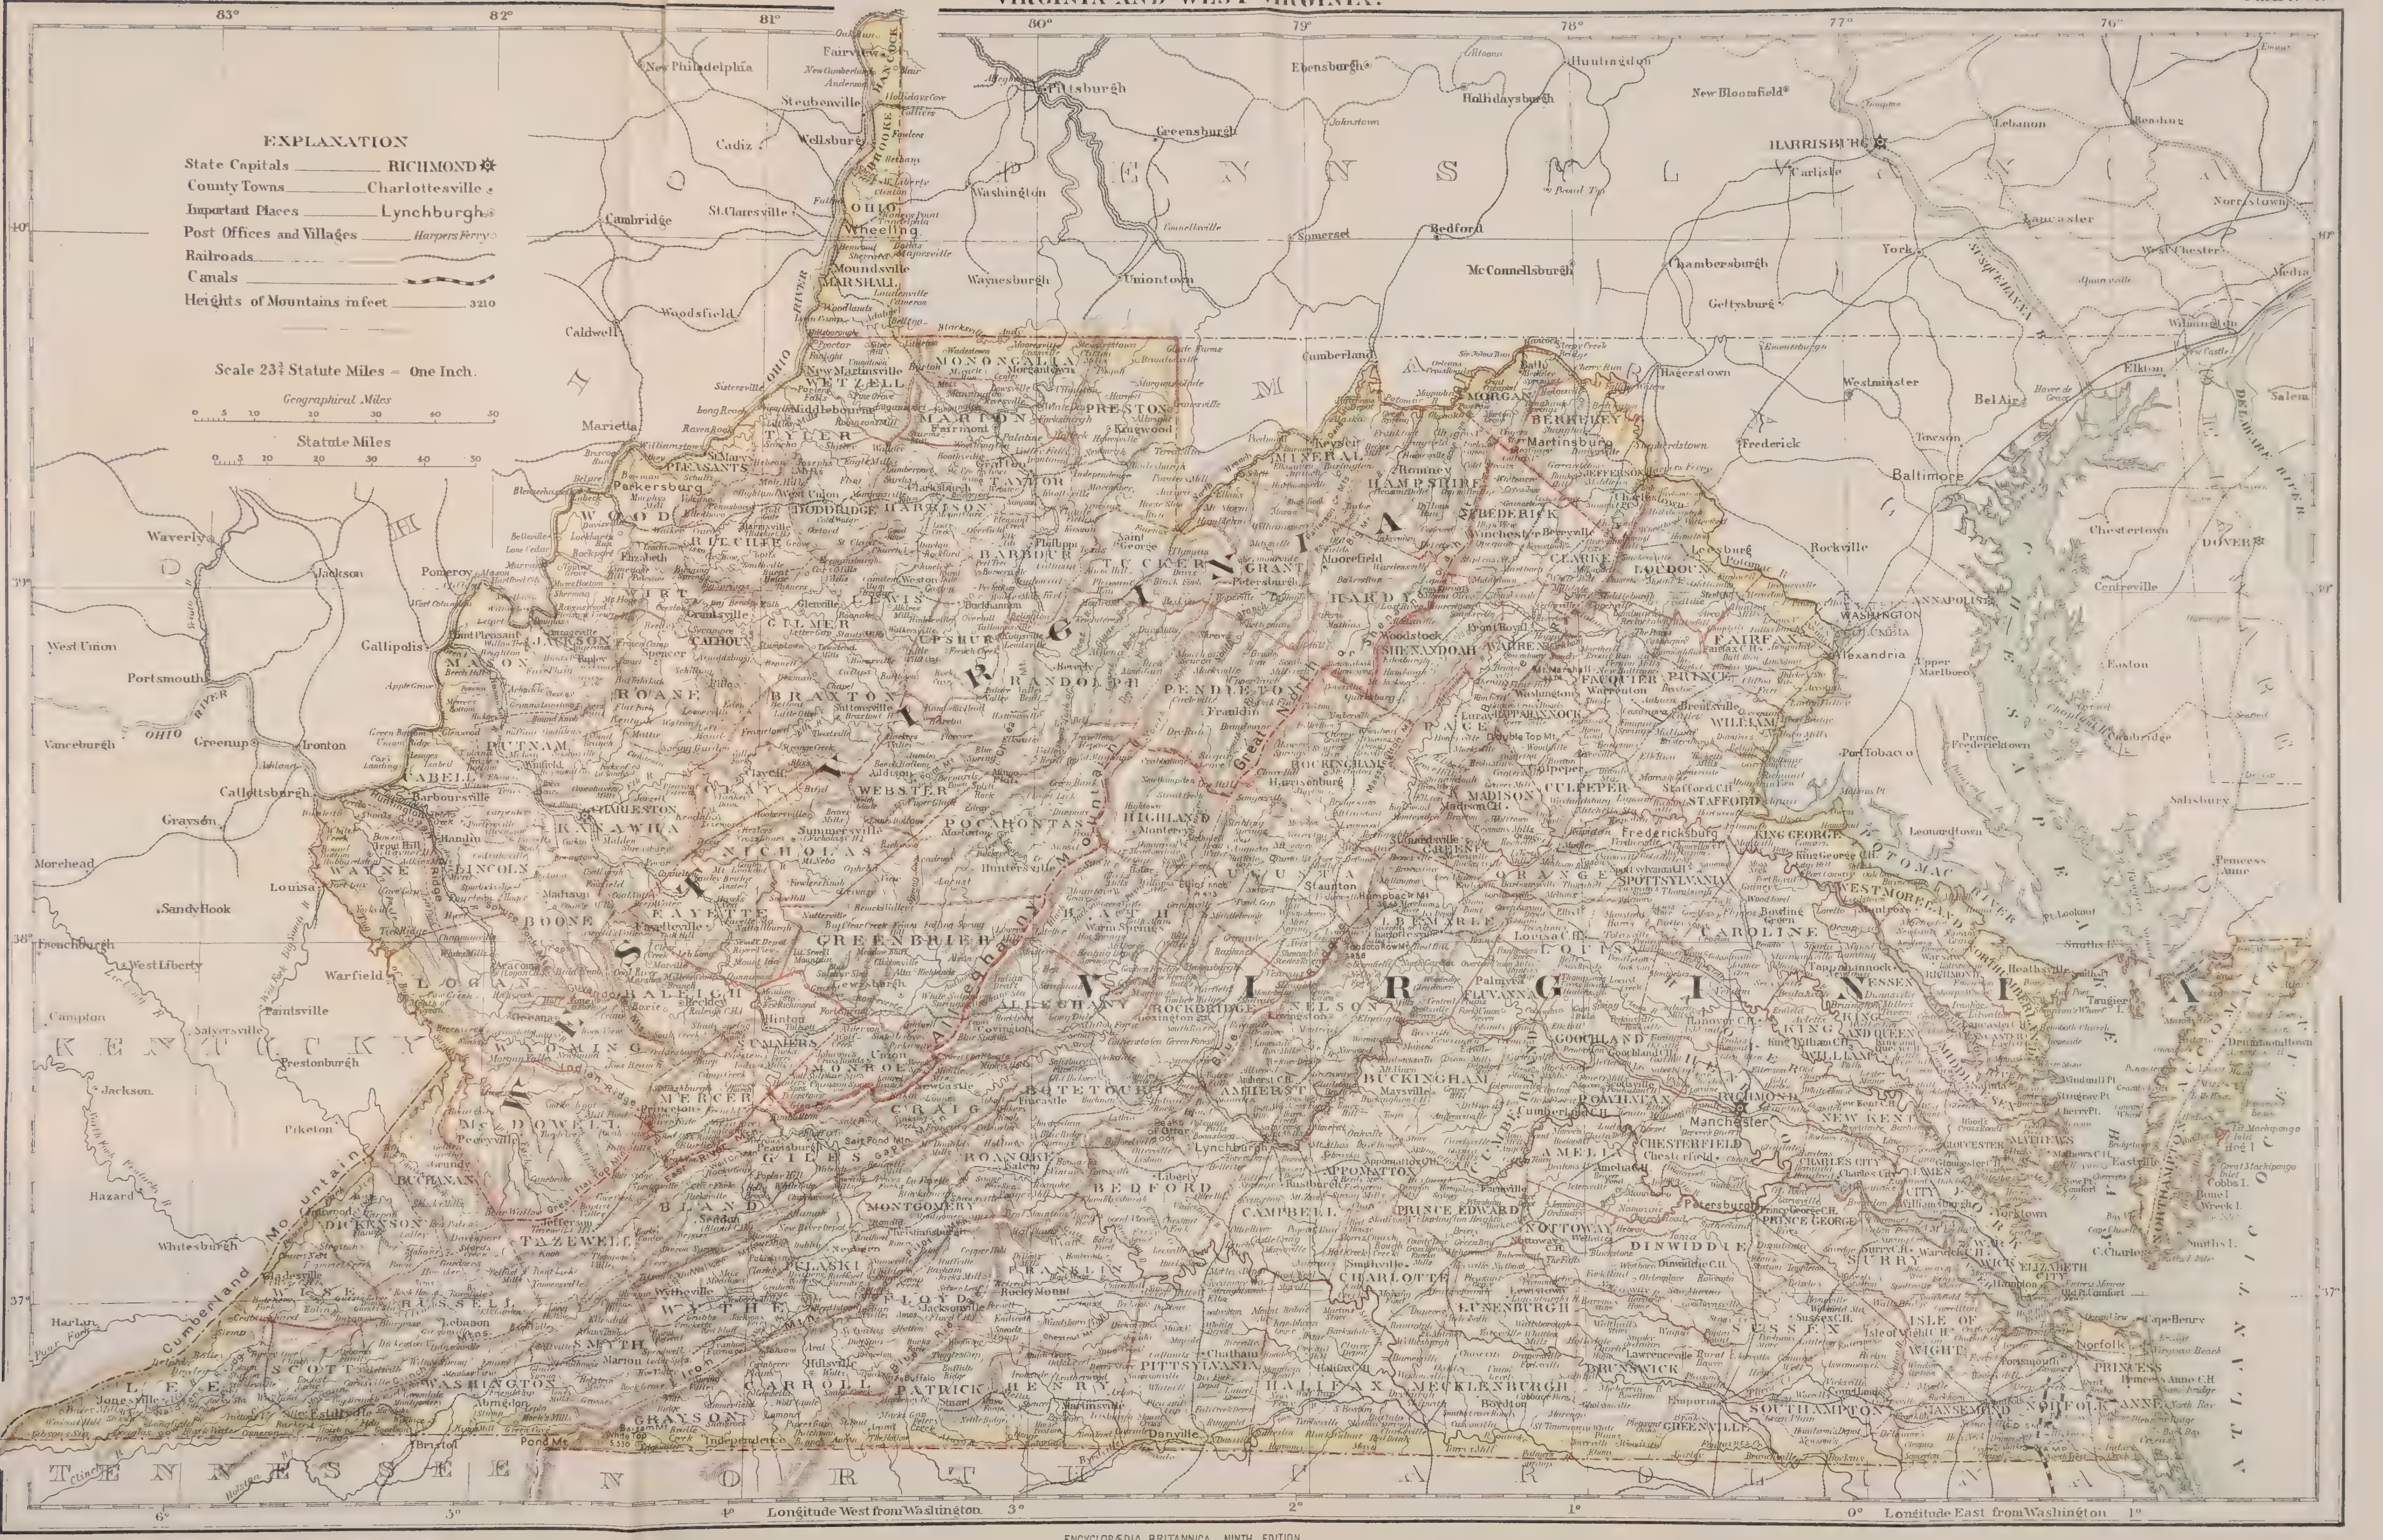
The first edition of the *Historia Anglica* (twenty-six books) was printed at Basel in 1534; the twenty-seventh book, dealing with the reign of Henry VIII. down to the birth of Edward VI. (October, 1536), was added to the third edition of 1555. Polydore claims to have been very careful in collecting materials for this work, and takes credit for using foreign historians as well as English; for which reason, he remarks, the English, Scotch, and French will find several things reported in his pages far differently from the way in which they are told in current national story. In his search after information he applied to James IV. of Scotland for a list of the Scottish kings and their annals; but not even his friendship for Gavin Douglas could induce him to give credit to the historical notions of this accomplished bishop, who traced the pedigree of the Scots down from the banished son of an Athenian king and Scotta the daughter of the Egyptian tyrant of the Israelites. A similar skepticism made him doubt the veracity of Geoffrey of Monmouth, and thus called forth Leland's *Defensio Gallofridi* and *Assertio Incomparabilis Arturii*. This doubting instinct led to his being accused of many offences against learning, such as that of burning cartloads of MSS. lest his errors should be discovered, of purloining books from libraries and shipping them off by the vesselful to Rome. As a matter of fact, it is of course mainly from the time of Henry VI., where our contemporary records begin to fail so sadly, that Polydore's work is useful. He must have been personally acquainted with many men whose memories could carry them back to the beginning of the Wars of the Roses. Dr. Brewer speaks somewhat harshly of him as an authority for the reign of Henry VIII., and indeed his spite against Wolsey is evident; but it is impossible to read his social and geographical accounts of England and Scotland without gratitude for a writer who has preserved so many interesting details. Polydore's *Adagia* (Venice, April, 1498) was the first collection of Latin proverbs ever printed; it preceded Erasmus's by two years, and the slight misunderstanding that arose for the moment out of rival claims gave place to a sincere friendship. A second series of Biblical proverbs (533 in number) was dedicated to Wolsey's follower Richard Pace, and is preceded by an interesting letter (June, 1519), which gives the names of many of Polydore's English friends, from More and Archbishop Warham to Linacre and Tunstall. The *De Inventoribus*, treating of the origin of all things whether ecclesiastical or lay (Paris, 1499), originally consisted of only seven books, but was increased to eight in 1521. It was exceedingly popular, and was early translated into French (1521), German (1537), English (1546), and Spanish (1551). All editions, however, except those following the text sanctioned by Gregory XIII. in 1576, are on the Index Expurgatorius. The *De Prodigiis* also achieved a great popularity, and was soon translated into Italian (1543), English (1546), and Spanish (1550). This treatise takes the form of a Latin dialogue between Polydore and his Cambridge friend Robert Ridley. It takes place in the open air, at Polydore's country house near London. Polydore's duty is to state the problems and supply the historical illustrations; his friend's to explain, rationalize, and depreciate as best he can. Here, as in the *Historia Anglica*, it is plain that the writer plumes himself specially on the excellence of his Latin, which in Sir Henry Ellis's opinion is purer than that of any of his contemporaries.

VIRGINAL. See PIANOFORTE, vol. xix. pp. 74, 75, 76, 78.

VIRGINIA, one of the original thirteen States of the North American Union, extends from 36° 31′ to 39° 27′ N. lat., and from 75° 13′ to 83° 37′ W. long. It is rudely triangular in form,—its southern boundary, the base of the triangle, a nearly east to west line, being 440 miles long, the northwestern 565, the northern and northeastern 230, and the eastern 125 miles. On the S. it is bounded by North Carolina and Tennessee, on the W. and N.W. by Kentucky and West Virginia, on the N. and N.E. by Maryland, and on the E. by the Virginian Sea of the Atlantic Ocean. Its greatest length from east to west is 476 miles, its greatest breadth from north to south 192 miles. It is subdivided into 100 counties. The area is variously stated at about 44,500 and 42,450 square miles; the latter extent is that given at the census of 1880. Of the 1,512,565 inhabitants of Virginia (1,059,034 of them over ten

Plate VII.

VIRGINIA AND WEST VIRGINIA.



years of age) in 1880, 494,240 were engaged in gainful occupations,—254,099, or over 50 per cent., in agriculture, 30,418 in trade and transportation, and 63,059 in manufactures and mining and mechanical industries; but now (in 1888) a very much larger proportion of the industrial population is engaged in mining, manufacturing, trade, and transportation, in consequence of the opening of mines, the erection of blast-furnaces, coke ovens, and various manufacturing establishments since 1880.

Physical features.

Physical Features.—Speaking broadly, Virginia may be divided into a lowland and a highland country. Its southeastern part—over 23,000 square miles, or more than half of the whole—has the aspect of a broadly undulating plain, that, with but few marked variations of relief, rises from the sea-level to from 400 to 800 feet above it. The northwestern portion is a region composed of approximately parallel mountain ranges, running entirely across the State from northeast to southwest, separated by nearly parallel valleys,—the whole presenting all the varieties of relief peculiar to the Appalachian country between the levels of 800 and 5700 feet. To speak more accurately, the State is naturally divided into seven grand divisions or belts, each with marked characteristics of relief and geological structure, and each succeeding the other, somewhat as a more or less ascending stairway, from the sea to the northwest.

1. Tidewater Virginia is the marine plain, of Quaternary and Tertiary structure, 10,850 square miles in area, that extends westward, for nearly 100 miles, from the Atlantic border to the "Ridge," the granitic escarpment which by its rise determines the tidal limit in the great rivers of the State. This Tidewater plain, rectangular in form, is divided by Chesapeake Bay and the great estuaries of the Potomac, the Rappahannock, the York, and the James rivers, into five large peninsulas, which are subdivided by arms of the bay and tidal branches of the rivers into hundreds of smaller peninsulas, thus giving to the region great wealth of tidal shore outline—fully 2000 miles—so that nearly every square mile of its surface can be reached by tide-borne vessels. The nearly level surface of its north to south trending peninsulas, those of the eastern marine plain, the Quaternary ones, averages about 12 feet above sea-level; their low-lying semi-insular position and their warm finely comminuted soils make these the highly favored great market-garden or "trucking" portions of Tidewater. The northwest to southeast trending peninsulas, those of the western marine plain, the Tertiary ones, have more broken surfaces that vary in altitude from sea-level to about 100 feet, and are disposed in flat watershed ridges and slopes, terraces and swamps, all deeply trenched by the secondary drainage.

2. Midland Virginia is the triangular area (12,470 square miles) which, 25 miles wide along the Potomac and 100 wide along the North Carolina line, extends from the Tidewater escarpment westward to the eastern base of the Atlantic coast range, the broken eastern range of the Appalachian Mountains. The elevation here varies from 100 to 200 feet above sea-level in the east to from 700 to 800 in the west; once a gently eastwardly sloping plain, mostly underlaid by steeply dipping granitic and other Archæan rocks—with included areas of Jura-Trias—striking northeast to southwest, the rivers have deeply trenched into this, and so given it a greatly broken and varied relief through a moderate range of altitude; it abounds in stream-valleys. This, with Piedmont and the Blue Ridge, was the first dry land, the oldest portion of Virginia.

3. Piedmont Virginia is the area (6680 square miles) of greatly diversified country, some 250 miles in length and 20 to 30 miles in width, that stretches between the Blue Ridge and the Coast Range mountains, including all of the latter and the eastward spurs and slopes of the former; its valleys, coves, and plains vary in altitude from 300 to 700 feet in the northeast to from 500 to 1000 in the southwest, while its included and bordering mountains range through all gradations from above 4000 feet down to the levels of its valleys. It is charmingly varied and picturesque, and adapted to a great variety of productions.

4. Blue Ridge Virginia is the Virginian portion (300 miles in length) of the great mountain chain of that name, with its numerous tablelands—especially the Floyd-Carroll-Grayson plateau (1230 square miles) in the southwest, having an altitude of from 916 to 5700 feet. It is, for most of its length, a chain of two ranges: the eastern, the chief, in which numerous rivers have their origin, is a grand mountain mass, carved from the Archæan and eruptive rocks, forming the most striking feature of thousands of square miles of Virginia landscape; the western is mainly composed of short ridges, formed from the easterly outcrops of the Palæozoic rocks, flanking the western slopes of the main range.

5. The Valley of Virginia is the Virginian portion (300 miles) of the length of the great limestone or Appalachian valley of the Atlantic highlands, one that, made up of numerous subordinate valleys, extends with unbroken continuity from Canada to Alabama, and has for its whole length, with varying local names, the Blue Ridge on its eastern and the Kittatinny or Great North Mountain on its western border. In Virginia this is a plateau-valley,—embracing 7550 square miles,—its greatly varied tillable surface ranging in altitude from about 500 to over 2500 feet and averaging fully 1000. Carved from the limestones and limy shales and slates of the Cambrian group into an almost endless variety of valley and upland forms, the higher ones in gracefully rounded outline, all blending into one or more broad valleys, and bounded by grand mountain chains, this is indisputably one of the most desirable regions in the United States.

6. Appalachia (4500 square miles), a region of alternating "rich" and "poor" valleys (according as they are carved from the lime-abounding or from the slaty sandstone rocks of the Silurian or the Devonian groups), is Virginia's portion of the Appalachian Mountains region proper, the one that lies between the Great Valley on the east and the great Carboniferous escarpment of the Trans-Appalachia plateau. Its general features are repetitions of long, parallel, straight and level-crested mountain ranges—many of them over 4000 feet—succeeding one another in echelon, with narrow, trough-like valleys,—ranging from 800 to 2700 feet,—but these are diversified by the occasional dying out of some mountain ranges and the consequent widening of valleys, and by the widening of ranges into plateaus or their opening into double crests or lovely mountain "coves" and "gardens." It is a noted grazing and timber region.

7. Trans-Appalachia (mainly the 1200 square miles in Buchanan, Dickenson, and Wise counties) is the Virginian portion of the tableland that extends westward from the great Carboniferous escarpment or Alleghany "backbone." It is eroded from the Carboniferous rocks, and so is the great coal-bearing portion of the State.

Climate.

Climate.—The State lies in the middle latitudes. It is open to the sea on the east; its great mountain chains guard it on the north and west; and it has accordingly as nearly a climate of means as any of the Atlantic-bordering States can have. Its position and physical structure also give great variety to its climate: that of its bordering sea islands and large peninsulas is insular; that of its great Tidewater and Midland plains is warm temperate; that of Piedmont and the Great Valley is typically mild temperate; and that of the Blue Ridge plateau and of the high valleys and table-lands of Appalachia is more uniformly cool temperate than in higher latitudes. Its climatic range, in the average latitude of 38° N., is from the sea-coast to 500 miles inland, and from the sea-level to 5700 feet, a range that is equivalent to 19° of latitude, and that gives to Virginia all the adaptations for production embraced between 36° 30′ and 59° N. lat. This wide range finds expression in the market-gardens and temperate fruits and trees and the extensive sweet potato, cotton, and peanut fields of Tidewater; in the large plantations of tobacco, hard-grained winter wheat, and the dented-seed (the large variety) Indian corn, and in great forests of pitch-pines, oaks, etc., in Midland and Piedmont, and in the lower portions of the Valley and Appalachia; in the productive vineyards and orchards of Piedmont and the adjacent slopes of the Blue Ridge; in the perennial pasture-lands—the native homes of the rich blue grass—of the higher levels of Piedmont, of the crests and plateaus of the eastern Blue Ridge, of the Great Valley, and of the extensive limestone valleys and ridges of Appalachia; in the large cereal crops and dairy products of the Valley; in the big cattle farms and ranges of Appalachia, the Blue Ridge, and the more elevated parts of the Valley; in the flax, buckwheat, Irish potato, cabbage, and other north-country crops that flourish in the Blue Ridge, the higher parts of the Valley, and Appalachia; and in the north-land balsams and other cold climate trees and vegetation that clothe the higher levels of the Blue Ridge and of Appalachia.

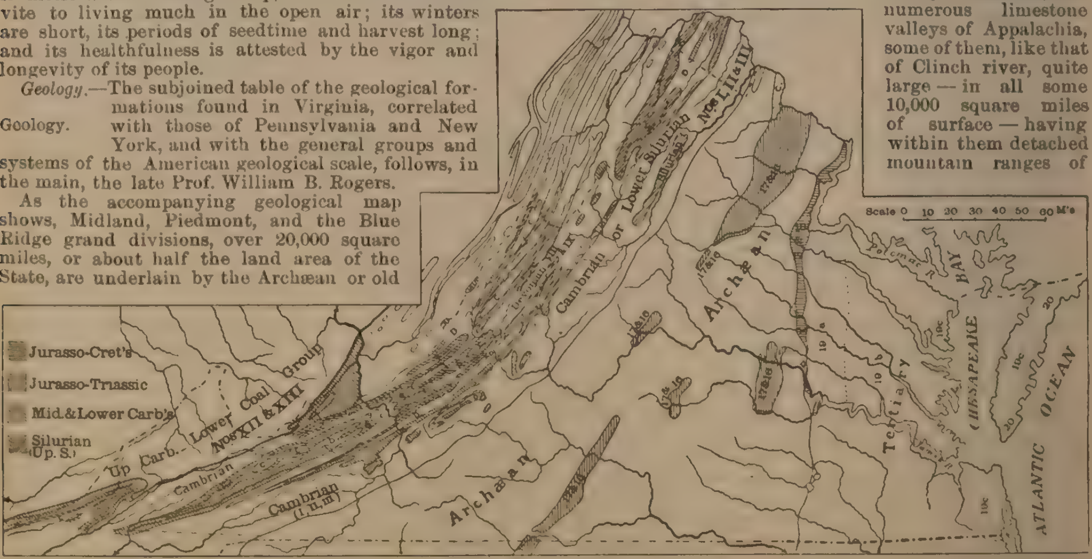
The mean annual temperature zones of Virginia are—60° to 65° in eastern Tidewater; 55° to 60° in western Tidewater, and most of Midland; 50° to 55° in the higher parts of Midland, in most of Piedmont, and in the lower parts of the Valley and Appalachia; 45° to 50° in northeast Piedmont, in most of the Valley, and in the lower valleys of Appalachia; and 40° to 45° on the Blue Ridge, on and near the high levels of the Valley, and in most of Appalachia. The average for the State is near 56°, ranging from 48° in the highlands to 64° in the lowlands—from the mean adapted to grass to that suitable for cotton. The changes of temperature are great, but not so sudden or so extreme as they are in the regions to the northeast and northwest.

The prevailing winds are from the south quadrants, generally shifting between south and west; next in frequency are those between north and west; high winds are rare, except along the coast. The rainfall is abundant and well distributed throughout the seasons in every part, there being two sources of supply, one from the Gulf by the southwest and one from the Atlantic by the southeast winds; the average annual precipitation is from 32 to 44 inches, except in a belt extending northwest from the mouth of Chesapeake Bay towards Staunton, in which it is from 44 to 56 inches; there is a gradual decrease in the rainfall from the coast westward. The snowfall is generally light, some winters insignificant; and the snow soon melts, save in the elevated regions.

Virginia is noted for the clearness of its skies, the purity of its air, and its freedom from great storms. Its climate is moist without being damp, and so mild as to invite to living much in the open air; its winters are short, its periods of seedtime and harvest long; and its healthfulness is attested by the vigor and longevity of its people.

Geology.

Geology.—The subjoined table of the geological formations found in Virginia, correlated with those of Pennsylvania and New York, and with the general groups and systems of the American geological scale, follows, in the main, the late Prof. William B. Rogers.



Geological Map of Virginia.

As the accompanying geological map shows, Midland, Piedmont, and the Blue Ridge grand divisions, over 20,000 square miles, or about half the land area of the State, are underlain by the Archæan or old Primary and metamorphic rocks; within this Archæan area are a dozen or more patches, large and small, of the Jura-Trias (formations 16, 17, and 18) or Mesozoic rocks, some of them with valuable coal-beds, that in later times were deposited in depressions, lake-like basins, in the

Subdivisions or Formations in Virginia.			General Groups.	Systems.
20.	Quaternary		Quaternary.	Cainozoic.
19*c*.	Pliocene (Upper Tertiary)		Tertiary.	
19*b*.	Miocene (Middle Tertiary)			
19*a*.	Eocene (Lower Tertiary)			
18 and 17.	Jurasso-Cretaceous (Upper Mesozoic)		Mesozoic.	Mesozoic.
17 and 16.	Jurasso-Triassic (Lower Mesozoic)			
14*b* (xiii.).	Middle Coal Group	Upper Carboniferous.[1]	Carboniferous.	Palæozoic.
14*a* (xii.).	Lower Coal Group			
13*b* (xi.).	Greenbrier shales and limestones (Carb. limestone)	Middle Carboniferous.		
13*a* (x.).	Montgomery grits and coal measures (Vespertine)	Lower Carboniferous.		
12 (ix.).	Catskill red sandstone (Upper Devonian)		Devonian.	
11*b* and *a* (viii.).	Chemung and Portage shales (Middle Devonian)			
10*c*, *b* and *a* (viii.).	Genesee, Hamilton, and Marcellus slates, etc. (Lower Devonian)			
8 (vii.).	Oriskany sandstone		Silurian (Upper Silurian).	
7 (vi.).	Lower Helderberg limestones			
5*b* (v.).	Clinton shales and sand rocks			
5*a* (iv.).	Medina and Oneida sand rocks			
4*c* and *b* (iii.).	Hudson River and Utica slates	Upper Cambrian.	Cambrian (Lower Silurian).	
4*a* (iii.).	Trenton and Great Valley limestones			
3*b*, *a* (ii.).	Calciferous, etc. (Great Valley dolomites, etc.)	Middle and Lower Cambrian.		
2 (i.).	Potsdam sandstones, shales, etc.			
1.	Archæan (Huronian, Laurentian, etc., Primary)		Primal.	

Note.—The first or Arabic numbers and the letters of the above are the numberings of the formations and their subdivisions now generally recognized and used in North America; the Roman numbers in brackets are the equivalent formations as numbered and used by the Rogers Brothers in the Pennsylvania and Virginia reports.

Archæan rocks. The Cambrian (Lower Silurian) areas, the Virginia formations i., ii., and iii., include all the Great Valley (limestone) and numerous limestone valleys of Appalachia, some of them, like that of Clinch river, quite large—in all some 10,000 square miles of surface—having within them detached mountain ranges of more recent formations. The Silurian (Upper Silurian) areas, those where the Virginia formations iv., v., vi., and vii., outcrop, are mountain ranges, detached once in the Great Valley, and ranges and chains of them in Appalachia, for these formations, made up largely of massive sand-rocks, are mountain-builders. The Devonian areas, Virginia formations viii., and ix., are principally those of the slaty or "poor" valleys of Appalachia, No. viii. being a formation from which stream-valleys are liberally carved, though ix., chiefly sand-rock, often holds it up to included or bordering ridges. The Lower and the Middle Carboniferous rocks, Virginia formations x. and xi., outcrop in long and narrow belts or strips of Greenbrier shales and limestones (xi.), and adjacent narrow and long mountain ranges of Montgomery grits and coal-measures (x.), in southwest portions of the Valley and of Appalachia, and in small mountain areas elsewhere in Appalachia. The Upper Carboniferous, Virginia formations xii. and xiii., the Lower (xii.) and the Middle (xiii.) Coal groups, underlie all the thousand square miles of Trans-Appalachia, where the semi-bituminous coking coals of the Lower Coal group are exposed, above water-level, in their best conditions of purity (high in carbon, low in volatile matter, and very low in ash, sulphur, and phosphorus) for metallurgical purposes, and in beds of remarkable thickness, and where the bituminous coals of the Middle Coal group also have a maximum of development combined with remarkable purity of composition, adapting them to gas and domestic uses. Tertiary rocks (19*a*, *b*, *c*) underlie all Tidewater (the new Virginia of geology, though the old one of colonial history),—the Lower or Eocene outcropping, approximately, in a line a little west of 77° W. long., the Middle or Miocene between that and a little east of 76° 30′ W., and the Upper or Pliocene in the remaining east part, except where covered by recent or Quaternary (20) deposits.

---

[1] Formations xiv., xv., and xvi., the Upper Coal group, are not known in the present limits of Virginia.

Minerals.

Minerals.—The varied and abundant mineral resources of the State are as yet imperfectly developed. Her medicinal mineral springs are numerous, and many of them well known. Tidewater abounds in fertilizing marls, and in choice brick-clays, sands, and shell-limestones for building. Lime burning, from oyster shells, is an important industry. Midland abounds in superior granites, which are extensively quarried near Richmond and Petersburg; in the best of slates for roofing and other purposes, especially in Albemarle and Buckingham counties; in Jura-Trias brownstones and sandstones; in trap for Belgian blocks; in soapstones (steatites), limestones, and in brick-, plastic-, and fire-clays. Thick beds of excellent bituminous coal and of natural coke are found in the Jura-Trias of Chesterfield and adjacent counties, which have long been mined; ochre beds are worked in Chesterfield county; thick beds of magnetic, specular, and limonite iron-ores, and of gold, silver, and copper-bearing rocks, traverse its whole length from northeast to southwest. Its gold belt, from 15 to 20 miles wide, rich in free quartz, and pyritous-rock gold, traverses the whole western tier of Midland counties, for more than two hundred miles, from the Potomac to the Dan; in this belt, in Louisa county, at the Arminius copper mines, veins of white pyrites, 42 feet, bearing 46 per cent. of sulphur and considerable yellow copper, have been opened and reduction works erected for a 300 tons daily output; 12,000 tons of pyrites were shipped in 1886. Manganese, mica, plumbago, titanium, cyanite, garnets, emeralds, quartz, and other Archæan and Jura-Trias minerals are found at many points. The minerals and metals now exploited are gold, iron and copper pyrites, manganese, hæmatites, magnetites, and limonites, mica, slates, granites, brownstones and trap-rock. Piedmont has extensive beds of magnetic, specular, and limonite iron ore throughout its length; chromic iron ore is found in the northeast; copper ores abound especially along the west border in spurs of Blue Ridge; manganese deposits have been worked at various points; the same Archæan and Jura-Trias building stones and minerals are found here as in Midland, the marbles of Bedford and Loudoun counties of fine quality. Iron ores, manganese, slates, and marbles are now exploited. The Blue Ridge abounds in copper and iron ores for its whole length in Virginia; these as well as pyritous silver, copper, and iron ores, are especially abundant in the Floyd-Carroll-Grayson or southwest plateau, where also auriferous quartz is milled; tin mines have been opened in Rockbridge county; the great Potsdam or primordial iron belt, with its vast deposits of ore, flanks the western base of the Blue Ridge in Virginia for nearly 300 miles, and from the rich deposits of manganese in the same belt two-thirds of the manganese output of the United States in 1886 was mined; glass-sand of the best quality and fire and other clays are abundant, and so are building sandstones in the western Blue Ridge. Mining operations are now extensively conducted in iron and manganese ores. The Great Valley is all underlain by limestones suitable for ornamental, building, and agricultural purposes; its cement (hydraulic) and architectural, fluxing, and agricultural limes are noted for their purity; extensive beds of iron-ore are found among its hills; marbles, barytes, brick- and fire-clays, and travertine marls are abundant; there are large deposits of lead and zinc ores, especially in the southwest, in Pulaski and Wythe counties, where they accompany the great iron-ore deposits of the Cripple Creek region; from the Vespertine (No. x.) beds of the Lower Carboniferous, in Montgomery and Pulaski counties, from 15,000 to 20,000 tons of semi-anthracite coal are annually mined; ochres are mined in Page and Augusta counties; iron, manganese, zinc, and lead ores are now mined on quite an extensive scale, and lime-burning is an important industry. Appalachian Virginia abounds in very remarkable beds of limonite iron ores, found (often, under large areas, in a more or less stratified condition) in the Hudson river (iii.), Clinton (v.), and Oriskany (vii.) formations of Cambrian and Silurian age; there are also deposits of magnetic hæmatites in Craig and Giles counties; limestones of the Valley (ii.), Trenton (iii.), and Lower Helderberg (vi.) formations, underlying the "rich" valleys and ridges, abound, and furnish the best of materials for building, lime-burning, and blast-furnace fluxing purposes, as well as for beautiful encrinal and other fancy marbles; in its Vespertine (x.) areas are numerous patches of anthracite and semi-anthracite coals, worked and workable for local use; in the Appalachian portions of Smyth and Washington counties are large deposits of rock-salt and gypsum; travertine marls, caves abounding in nitrous earths, and chalybeate, sulphur, alum, hot, warm, and other mineral springs are common; sandstones and slates for building purposes are plentiful. The iron-ores of Alleghany county and those of the Appalachian portions of Rockbridge and Botetourt counties are extensively mined for local blast-furnaces; marbles and gypsum are quarried; considerable salt is manufactured, and semi-anthracite coal in Pulaski for use in local zinc furnaces. Trans-Appalachia is Virginia's 1000 square miles of the Great Coal Basin of the Ohio, or the Trans-Appalachian Coal Basin (the one usually, but improperly, called the Great Appalachian Coal Basin); this is all underlain by thick and easily accessible beds of the best of semi-bituminous and bituminous coals, those of the Lower (xii.) and of the Middle (xiii.) Coal groups of the Carboniferous. Only the semi-bituminous coking, steam, and domestic coal of this region is now mined for exportation at Pocahontas, Tazewell county, from which 639,751 tons (93,550 of them converted into coke) were shipped in 1886, the traffic having begun with the shipment of 105,805 tons in 1883. From the Flat-top coal-field, including the Pocahontas and some adjacent mines in West Virginia, 1,314,700 tons of coal were mined in 1887, part of which was made into about 145,000 tons of coke, equal in quality to any made in the United States. This fuel is remarkably high in fixed carbon and low in ash and sulphur, and therefore admirably adapted for metallurgical purposes. Twenty mineral springs of Virginia, used medicinally, were reported to the United States Geological Survey in 1886 (Tidewater 1, Midland 4, Blue Ridge 2, Valley 5, Appalachia 8); they were reported as chalybeate, alum, white sulphur, red sulphur, blue sulphur, warm sulphur, cold sulphur, hot sulphur, lithia, healing, ague, and sweet chalybeate. These and many others not reported are visited as health resorts, and many of them ship to market large quantities of their waters.

Virginia produced—of coal 300,000 tons in 1884, 1,000,000 in 1886, and about 1,250,000 in 1887; of coke 25,340 tons in 1884, about 122,352 tons in 1886; of pig iron, 29,934 tons in 1880, 152,907 in 1883, 156,250 in 1886, and 156,698 in 1887; of rolled iron 40,581 tons, and of cut nails 212,552 kegs of 100 ℔ in 1886; of manganese 3661 tons in 1880 and 20,567 tons in 1886; of pyrites 12,000 tons in 1886; of ochre 1750 tons in 1886; of salt, gypsum, lead, zinc, granite, slates, lime, limestone for blast-furnace flux, cement, brownstone, mineral waters, and iron-ore for export large quantities were produced in 1886, and still larger in 1887, when the mining industries of this State were in a healthy condition of development.

Vegetation.

Vegetation.—The variety of vegetation in Virginia is very great, the range being from a profitable growth of semi-tropical cotton to semi-arctic pines and balsams. From one-half to two-thirds of the State is now covered by forests of native evergreen and deciduous trees. Hard and soft woods in nearly equal proportions from the original forests of Tidewater and Midland, —the plain region; hard woods predominate in the high country divisions; the park-like hardwood forests of the Great Valley have grown up since its occupation by white men.

The census report of 1880, in its natural divisions of

North American forests, assigns the east maritime plain of Tidewater to the coast-pine division; the northeast portions of Blue Ridge, Valley, and Appalachia to the northern-pine division; and the rest of the State to that of deciduous trees. The principal timber trees, found in varying abundance in all parts, are white, Spanish, black, chestnut, red, post, and swamp oaks; tulip-poplar and cucumber; white (or shell), bark, and pignut hickories; yellow or pitch pine; red or Virginia cedar; beech, elm, black and white walnuts, sycamore, mulberry, locust, sassafras, and gum; sugar, red, and white maples; black, red, and yellow birches; wild cherry, persimmon, dogwood, ironwood; white, red, black, and water ashes; chestnut, and willows. Cypress, juniper, long-leaved pine, holly, sweet gum, and some live oaks are confined mainly to Tidewater and east Midland; white pine, hemlock, black spruce, rock chestnut oak, and balsams to the mountain regions; the oaks of the Valley are of rare excellence, and the tulip-poplars and oaks of Trans-Appalachia and its borders are of remarkable size; sumachs, millions of pounds of the leaves of which are gathered for their tannin, are everywhere plentiful. From the sugar-maple, considerable quantities of sugar are made in the Valley and the Appalachias; the forests of Tidewater, easily reached by vessels, furnish large quantities of fuel and lumber to seaport markets; railways reach the other timber regions of the State; lumbering, charcoal-making, the cutting of railway sleepers, and the collection of tan-bark, are important industries. Wild fruits and nuts, gooseberries, blackberries, whortleberries, cranberries, strawberries, haws, serviceberries, persimmons, plums, crab and thorn apples, cherries, various wild grapes, chestnuts, chinquapins, black and white walnuts, hickory nuts, hazel and beech nuts, acorns, etc., are nearly all found in all parts. Medicinal roots (ginseng, sarsaparilla, snake-root, mandrake, etc.) are gathered in large quantities in the Appalachias; oil from sassafras roots is made in quantities in Midland and Piedmont. All the cultivated fruits of temperate climates flourish; apples, pears, peaches, grapes, plums, cherries, currants, and other small fruits are everywhere plentifully grown; the peach, pear, and apple orchards of Midland, Piedmont, Blue Ridge, and the Valley are noted; the vineyards of Midland, Piedmont, and Blue Ridge are becoming well known for both grapes and wines in variety; in Tidewater and eastern Midland figs, apricots, nectarines, and other warm country fruits flourish, and the scuppernong grapes and wines of Tidewater are also worthy of mention. The flora of Virginia includes nearly every species of plant found in the United States east of the Mississippi, excepting only the extreme south. The cleared lands of the State, about two-sevenths of the whole, are devoted to orchards, vineyards, meadows, and pastures, to market and other gardens, and to crops of maize (Indian corn), wheat, oats, rye, buckwheat, barley, pease, beans, peanuts, round (Irish) and long (sweet) potatoes, turnips, cabbage, clover, flax, hemp, cotton, tobacco, etc. Cereal and root crops are abundantly grown in all parts, as also are tobacco, hay, clover, and grass seed, flax and flaxseed, hops, hemp, and cotton. Nearly half the State, part of Piedmont and all Blue Ridge, the Valley, and the Appalachias is a natural grass country—half of it the habitat of the famous blue grass—and well adapted to grazing and dairy-farming; the special crops of Tidewater are those of market-gardens, early vegetables, and round and sweet potatoes in the east, and of peanuts and cotton in the west; tobacco is a specialty of southwest Midland and Piedmont.

Animals.

Fauna.—The buffalo and elk, common when white men first settled here, are now extinct; deer, red and gray foxes, rabbits, hares, ground-hogs or woodchucks, red, gray, and ground squirrels, opossums, skunks, muskrats, martens, minks, weasels, bats, rats, and mice are found everywhere; otters and beavers, once numerous in all parts, are again becoming common in south Midland and elsewhere; black bears frequent the Appalachian and borders of the adjacent valley divisions [and the Great Dismal Swamp], wild-cats, catamounts, and the small wolves are occasionally met in unfrequented portions of the mountain regions. Of game or food birds, partridges (quails), pigeons, wood doves, grouse (pheasants), larks, thrushes, snipe, wild turkeys, and several kinds of wild ducks are found in nearly all parts; the coasts, the inland bays, the great estuary rivers, and the marshes of Tidewater fairly swarm, especially during the colder months, with canvas-back, mallard, creek, redhead, bald-face, teal, and other wild ducks, and with wild geese, swans, snipe, and other water and water-side fowl; gulls and other sea birds frequent the coast. Song-birds, including mocking-birds, orioles, bobolinks, robins, catbirds, bluebirds, wrens, tanagers, sparrows, etc., abound; the English sparrow is domiciled in all the cities and towns; humming-birds are plentiful. The common birds of prey, eagles, hawks, owls, a vulture (the turkey-buzzard); the wading birds (herons, grass snipes, fly-up-the-creeks, etc.) and the various swimming birds are abundant. The common reptiles include land and water tortoises, or turtles and terrapins (some highly prized for food), and harmless snakes, useful in the destruction of vermin, frogs, toads, salamanders, etc.; the poisonous rattlesnakes, copperheads, and moccasins are sometimes encountered, but are not numerous; the comparatively harmless black snakes are more common. Of edible saltwater fishes, more than thirty kinds are taken in quantities in Chesapeake Bay waters, including sturgeon, rock-fish, trout, chub, sheepshead, spot, sunfish, bluefish, shad, herring, anchovy, Spanish mackerel, cod, bonito, drum, menhaden, bass, sea-eels, and hog-fish; while dozens of kinds not used for food are known. The freshwater fishes are perch, pickerel, cat-fish, chub, bass, sucker, fall-fish, salmon, hog-fish, red-horse, red-eye, carp, mullet, sunfish, eels, and trout in the mountain streams. Of the abounding crustaceans, edible crabs and lobsters are caught in great numbers in the marine waters, and millions of bushels of oysters, clams, and other shell-fish are annually sent to market.

Government.

Government.—The government is entrusted to three departments, each with distinct and separate powers. (1) The legislative authority is vested in a general assembly, composed of a house of delegates of 100 and a senate of 40 members which meets biennially at Richmond; the members of the house of delegates are elected for two years, those of the senate for four,—half the latter being elected biennially. (2) The executive authority is vested in a governor, elected by the people for four years. A lieutenant-governor is elected at the same time, who is president of the senate, and should a vacancy occur during the term of office becomes governor. The other executive officers are a secretary of the commonwealth, a treasurer, first and second auditors of public accounts, a superintendent of public printing, a superintendent of the penitentiary, a railroad commissioner, a commissioner of agriculture, a registrar of the land office, and a superintendent of public instruction. (3) The judicial authority is vested—(*a*) in justices of peace, three in each of the magisterial districts into which the counties are subdivided; (*b*) in judges of county courts; (*c*) in judges of the seventeen circuit courts into which the State is divided, and judges of city courts; and (*d*) in a supreme court of appeals of five judges. The right of appeal, with specified limitations, is provided for from each of the above courts to the other, in the order named; the supreme court has only appellate jurisdiction save in cases of habeas corpus, mandamus, and prohibition. The justices of the peace, a supervisor, a constable, and an overseer of the poor are elected by the voters of each magisterial district to serve two years; the general assembly elects the county judges for terms of six years, the circuit judges for terms of eight years, and the judges of the supreme court of appeals for terms of twelve years. An attorney-general for the State is elected at and for the same time as the governor. In the Congress of the United States, Virginia has two senators and ten representatives. Aliens can acquire and hold any property in Virginia on the same footing as citizens.

Population.

Population.—The population of Virginia before the separation of West Virginia in 1862 is shown by Table I.

TABLE I.

Census.	Population.	Increase per cent.	Persons per sq. mile.	Census.	Population.	Increase per cent.	Persons per sq. mile.
1790	747,610	....	11.5	1830	1,211,405	13.7	18.7
1800	880,200	17.7	13.6	1840	1,239,797	2.3	19.1
1810	974,600	10.7	15.0	1850	1,421,661	14.6	21.9
1820	1,065,116	9.2	16.4	1860	1,596,318	12.2	24.6

In 1870 the population of Virginia was 1,225,163, and that of West Virginia 442,014. In 1880, while West Virginia had 618,457 inhabitants (39.9 per cent. increase), Virginia had 1,512,565 (745,589 males, 766,976 females),—an increase of 23.4 per cent., with 37.7 persons to the square mile.

Table II. shows the distribution of the population in 1880 according to the grand divisions. There were in addition 6 Chinese and 85 Indians. The number of foreign-born, 14,696, does not amount to 1 per cent. of the population.

The original stock of the whites was mainly English, Scottish, and Huguenot French in Tidewater, Midland, and Piedmont, and Scottish (largely Scoto-Irish from migrating by way of Ireland), German, and English in the remainder of the State—in proportions in the order named.

TABLE II.

	White.	Colored.
Tidewater	201,578	213,691
Midland	198,140	245,151
Piedmont	148,138	103,620
Blue Ridge	37,029	2,617
The Valley	199,628	51,478
The Appalachias	96,345	9,059
Virginia	880,858	631,616

Cities.

Virginia has six cities with over 10,000 inhabitants. In 1880 Richmond, the State capital, had 63,600, Norfolk 21,966, Petersburg 21,656, Lynchburg 15,959, Alexandria 13,659, and Portsmouth 11,390,—Danville coming next with 7526.

Education.

Education.—The public school system of the State, organized in 1870, provides (1) primary and (2) intermediate instruction in the common branches of education, including preparation for college, by graded primary and high schools—the latter confined to cities, towns, and large villages—free to all between the ages of five and twenty-one inclusive; (3) advanced instruction and training in scientific and professional studies, by a military institute, an agricultural and mechanical college, male and female normal schools, and an institution for the deaf-mutes and the blind—all for whites, and by a normal and agricultural institute and normal college for colored pupils,[1]—tuition free to a selected number from all parts of the State; and (4) higher instruction, in the complete academic, scientific, technical, and professional schools of the university of Virginia, its academic department tuition free to all young men of Virginia, over eighteen years of age, under restrictions in regard to culture. The State schools confer no honorary degrees. Equal provision, but in entirely separate schools, is made by law for white and colored.

The public free school system is in charge of a board of education. In 1887 the school population, those between five and twenty-one, numbered 610,271 (345;022 white and 265,249 colored); 7140 schools (5047 white and 2093 colored) were open, including 458 graded schools; 7161 teachers (2416 white males, 2889 white females, 1023 colored males, and 833 colored females) were employed; 325,184 pupils (209,638 white and 115,546 colored) were enrolled, and 184,520 (121,571 white and 62,949 colored) were in average daily attendance. The school districts owned 4365 schoolhouses, and their school property was valued at $1,907,775; the expense of the free school system in 1887 was $1,381,690, besides $153,600 spent on permanent improvements. The State makes liberal grants to the military institute, the agricultural and mechanical college, the normal and agricultural institute, the three normal schools, and the university.

Private and corporate schools embrace academies and high schools for boys, preparatory for college or university; female colleges, mainly under denominational control; and the well-known colleges of St. John's in Tidewater;[2] Hampden-Sidney, Randolph-Macon, Richmond, and Virginia Medical in Midland; and Roanoke, Emory and Henry, and Washington and Lee University in the Valley. The college of William and Mary (founded in 1693), suspended by reason of losses during the civil war, is now a normal school.

Crime.

Prisons.—One penitentiary, at Richmond, provides for all convicted of serious crimes in Virginia; during 1885–86 it received 337 convicts (80 white, 257 colored); its expenses were $98,978, and the labor of the convicts yielded $78,000. Each county has a jail for persons committed for petty offences or awaiting trial.

Lunacy.

Pauperism.

Deaf-mutes and blind.

Lunacy, etc.—There are four first-class lunatic asylums,—at Williamsburg, Staunton, and Marion, and (for colored patients) at Petersburg. In 1885–86 there were 1479 patients in the State's three asylums, for which it contributed $345,077. The census of 1880 returned 2411 insane,—1171 males, 1240 females, 1719 white, and 692 colored. Pauperism is not common in Virginia; in 1870 there were only 3890 paupers, supported by public charity at a cost of $303,081; in 1880 the total number was 3138, 2117 of these being in almshouses, of whom 1027 were colored. Deaf-mutes and blind are well cared for in a noble institution at Staunton, which trained during 1885–86 78 deaf-mutes and 44 blind, with an annual grant of $35,000. The disabled Confederate soldiers of Virginia are aided by the State ($83,040 in 1885–86). There is also near Richmond, a soldiers' home.

Agriculture.

Agriculture.—More than 50 per cent. of the laboring population was in 1880 engaged in agriculture. According to that year's census the land area was 25,680,000 acres, 19,835,785 of which (0.772 of the whole) were embraced in 118,517 farms, although only 8,510,113 acres of such area (only two-sevenths of the whole) were under cultivation (leaving 57.1 per cent, of land in farms unimproved), yet the number of farms increased 60.5 per cent. and the acreage in farms 9.3 per cent. from 1870. Seven-tenths of its farms were cultivated by owners; over half of the remainder were rented for a share of the crop, and the other part for a fixed money rental. The average size of farms was 167 acres; but there were 53,101 containing from 100 to 500 acres, 5561 with from 500 to 1000 acres, and 1563 containing over 1000 acres each,—so that more than half the farms contained from 100 to over 1000 acres each, or a probable average of 300 acres each, large farms being the rule. The farms and their improvements were valued at $216,028,107, their farming implements at $5,495,114, the live stock at $25,953,315; for improvements $1,697,180 and for manures $2,137,283 were spent, and the value of their products was estimated at $45,726,221. The live stock comprised 218,838 horses, 33,598 mules and asses, 54,709 working oxen, 243,061 milch cows, 388,414 other cattle, 497,289 sheep, and 956,451 swine. The wool clip was 1,836,673 ℔; 1,224,469 gallons of milk were sold; 11,470,923 ℔ of butter and 85,535 of cheese were made; 859 acres of barley yielded 14,223 bushels; 16,463 of buckwheat 136,004; 1,768,127 of Indian corn 29,119,761; 563,443 of oats 5,333,181; 48,746 of rye 324,431; 901,177 acres of wheat yielded 7,826,174 bushels; 45,040 acres of cotton 19,595 bales; the flax crop was 4526 bushels of seed, 16,430 tons of straw, and 66,264 ℔ of fibre; the sorghum crop was 143 ℔ of sugar and 564,558 gallons of molasses; from the sugar maple were made 85,693 ℔ of sugar and 7518 gallons of molasses; of hay 286,823 tons were grown on 336,289 acres; 17,806 bushels of clover seed and 41,722 bushels of grass seed were raised; there were 1,987,010 barn-yard and 660,147 other fowls, and 8,950,629 dozen eggs were produced during the year; 1,090,451 ℔ of honey and 53,200 of beeswax were made; on 140,791 acres were grown 79,988,868 ℔ of tobacco; 2,016,766 bushels of Irish potatoes were raised, and on 23,755 acres 1,901,521 bushels of sweet ones; orchard products were valued at $1,609,663, and market-garden products at $837,609; 2,177,770 cords of wood, valued $3,053,149, were cut; the wool-clip was valued at $1,836,673; 12 acres of hops yielded 1599 ℔, and 127,976 ℔ of broom corn were grown; the crop of peas was 77,758 bushels, and that of beans 45,411. Of the 8,510,113 acres of improved land, 1,152,083 were in permanent meadows, pastures, orchards, and vineyards, and 7,358,030 were under tillage; of the 11,325,672 acres unimproved in farms, 9,126,601 were in woodland and forest, and 2,199,071 in old fields, etc. Virginia was one of the twenty States that produced over 20,000,000 bushels of Indian corn each, ranking thirteenth; it stood second to Kentucky in acreage and quantity of tobacco grown. The United States commissioner of agriculture estimates that in 1884 Virginia had 4,071,401 acres in crops, producing 44,000,000 bushels of cereals, 2,061,000 bushels of potatoes, 99,763 ℔ of tobacco, 366,389 tons of hay, and 13,500 bales of cotton, valued at $39,050,052; and had on its farms 2,127,023 domestic animals, worth $39,608,536.

Manufactures.

Manufactures.—Though Virginia has great natural advantages for becoming a leading manufacturing State, in 1870 less than 12 per cent. of its population was engaged in manufacturing industries. In 1880, however, its 5710 establishments had invested $26,968,990, employed 40,184 persons (28,779 men), paid $7,425,261 for wages and $32,883,933 for materials, and produced to the value of $51,780,992,—a gain of nearly 60 per cent. in ten years. It is estimated[3] that the value of the products in 1885 was $75,000,000,—a gain of over 44 per cent. in five years. The sales of products of the manufacturing establishments of Richmond city alone amounted in 1887 to $27,887,340. The pig-iron output in 1887 was worth over

---

[1] [This institution for colored students is at Hampton. The agricultural college for whites is at Blacksburg.—AM. ED.]

[2] St. John's Roman Catholic Theological Seminary is at Norfolk, but no such college is found in the *Reports* of the U. S. Commissioner of Education.—AM. ED.]

[3] *United States Internal Commerce Report* for 1886.

$3,000,000. The more important manufactures are those of iron, tobacco, leather, coke, cotton, manures, paper, agricultural implements and machinery, builders' materials, vehicles, lumber, lime, tanning extracts, railway cars and locomotives, flour and mill products, spelter, salt, distilled spirits, canned fruits, vegetables, etc.

Communication.

Communication.—The navigable tidal bays, creeks, rivers, harbors, and roads of Tidewater Virginia furnish more than a thousand miles of channels for commerce; Richmond, at the head of the tidal waters of the James, 117 miles from Chesapeake Bay, is reached by ocean ships drawing 15 feet of water; West Point, at York Head, 41 miles from the bay, has 18 feet of depth; Elizabeth river gives to the fine harbor of Norfolk a channel 25 feet deep; while Hampton Roads, with its 400 square miles of area,[1] is the largest as well as the most central and commodious landlocked harbor on the Atlantic coast of the United States. Ship canals connect the great waterways of Virginia with those of North Carolina and beyond to the southward; and, similarly, northward the head of Chesapeake Bay is connected with Delaware Bay. At the beginning of 1888 there were 35 railway companies working 2540 miles of road, all of standard 4 feet 9 inches gauge, except some 256 miles of narrow-gauge short lines. The Virginia railways earned $13,825,909 in 1885 at an outlay of $8,999,853, the work done being equivalent to 971,477,375 mile-tons. Virginia early took part in the construction of railways, investing many millions in the stocks of the various lines now reaching nearly every part of the State; beginning about 1830, it had 147 miles of railway in 1840, 384 in 1850, 1350 in 1860, 1449 in 1870, 1893 in 1880, 2430 in 1885, and 2540, with some 200 miles more in course of construction, at the beginning of 1888. Eight great through railway lines connect its trade and manufacturing centres with those of other States.

Finance.

Finance.—For the year ending September 30, 1886, the assessed value of the real estate of Virginia was $257,607,935, and of personal property $83,152,971, or $340,760,906 of taxable valuation; the taxes were $1,029,936 on real estate, $336,366 on personal property, $39,112 on incomes, $316,293 capitation, $141,755 from railways on a valuation of $34,614,427, $299,343 from liquor and $400,325 from other licenses. The receipts of the State were $2,773,437, and its expenses of all kinds $2,755,036; of these $657,610 went to the support of the free public schools and $1,064,097 to the support of the State Government. The rate of taxation is low, and on a low property valuation. The State debt at January 1, 1885, was $28,961,829.

Militia.

Militia.—In 1880 the natural militia (male persons from eighteen to forty-four years of age inclusive) was 264,033 (102,426 of them colored) in a male population of 745,589. The organized militia force is small. In 1885–86 there were 51 equipped volunteer companies of active militia under the orders of the State,—mainly in its cities and larger towns,—43 of infantry (18 of them colored), 5 of artillery, and 3 cavalry,—mustering in all 2904 men. The Virginia military fund is about $11,000 a year.

History.

History.—The mound-builders of the Mississippi valley had outposts, as evidenced by remains of their earthworks, in the mountain passes of Appalachia. At the time of the arrival of the whites the Powhatans held most of Tidewater, the Mannahoacks the northeast and the Monacans the southwest of Midland and Piedmont; the Cherokees held the Tennessee basin parts of the Valley and Appalachia, and Algonkin tribes—Shawnees, Delawares, etc.—the rest of those divisions. Many of the place names are still Indian. Cabot probably entered Chesapeake Bay in 1498; when Raleigh's ships, in 1585, brought to England glowing accounts of the Albemarle Sound region, the whole country was named Virginia in honor of Elizabeth, the virgin queen.[2] The first permanent English settlement in America was made at Jamestown, Virginia, May 13, 1607, by one hundred settlers sent from England by Sir Thomas Gates and Company, who had obtained in April, 1606, a charter from James I. to plant two colonies in Virginia,—a southern somewhere between 34° and 41°, and a northern between 38° and 45° N. lat., but at places not less than 100 miles apart. In 1609 the London Company superseded Gates's, which had merely held its settlement and given to the world the romantic adventures of Captain John SMITH (*q.v.*). King James gave the London Company, by charter, a sea-front of 400 miles—200 north and 200 south from Point Comfort,—all islands within 100 miles of the coast, and all the country back from this 400 miles of frontage "throughout from sea to sea," and to its colonists all the rights of natural-born Englishmen; under this charter Virginia had jurisdiction over her imperial colonial territory, and under it holds the fragment of that colony now called Virginia. The colony of the London Company grew and prospered, and in 1619 Governor Yardley organized at James City, the capital, a few miles inland from Jamestown, the first legislative body that met in North America; in 1621 the London Company granted the colony a liberal constitution, the general form of which Virginia has always preserved. In August, 1619, a Dutch man-of-war sold at Jamestown twenty African negroes, and introduced negro slavery. In 1624 James I. arbitrarily deprived the London Company of its charter, and Virginia became a royal colony, which was, till the revolution, a favorite and generally a loyal royal province governed by the constitution of 1621, the king appointing the governor and council and the people electing the members of the house of burgesses. In 1700 the capital was transferred to Williamsburg, where, under royal patronage, William and Mary College had been established in 1693. The colony soon occupied most of Tidewater and its Midland border; in 1716 Governor Spotswood crossed the Blue Ridge, and was, so far as known, the first white man to enter the Great Valley, which was soon thereafter occupied by large numbers of Scottish and some German and English settlers. Indian wars followed as settlers moved westward, but in 1744 Virginia purchased from the Indians the right to make settlements to the Ohio, and built a fort where Pittsburgh now stands; the French captured this in 1754, and the long French and Indian war followed, until the 1763 treaty of Paris ended it and made the Mississippi the western boundary of Virginia. During that war, in 1755, Braddock was defeated; and in 1758 Fort Duquesne, which under the French had taken the place of Pittsburgh, was captured and renamed Fort Pitt. In 1773 the general assembly of Virginia resolved for an "inter-colonial committee of correspondence," and was dissolved by Lord Dunmore, the royal governor. In May, 1774, it again met and protested against the closing of the port of Boston; Dunmore again dissolved it, but the burgesses, the members elected by the people, reassembled and passed resolutions denouncing British taxation and recommending to the other colonies an annual congress of delegates,—leading in this as it had in recommending committees of correspondence. Virginia took a leading part in the subsequent war of independence, but the various steps of her policy need not be detailed here (see UNITED STATES, and compare also JEFFERSON and WASHINGTON).

The great territory of Virginia, reaching from the Atlantic to the Mississippi, and now divided into five large States, made the other States of the Union apprehensive of her future domination. In 1781, to promote harmony, she offered to cede to the general Government all her territory beyond the Ohio, and in 1784 she made the cession, only stipulating that the territory thus voluntarily given up should, when peopled, be divided into new States, in which slavery should be forever prohibited, and that the remainder of her territory—that from the Atlantic to the Ohio—should remain inviolably hers. In 1787 the convention of the States, at Philadelphia, presided over by Washington, adopted the present constitution of the United States, and this Virginia, in convention, ratified in 1788. In the war of 1812–14 with England Virginia bore a conspicuous part, as also in that of 1846–47 with Mexico. The civil war of 1861–65 was more disastrous in its consequences to Virginia than to any other State of the Union; from first to last its territory was overrun, hundreds of battles and minor engagements took place within its borders, and all the destruction incident to gigantic military operations fell upon it; tens of thousands of its best men were killed in battle; its territory was dismembered, and a third part of it cut off, while more than three hundred million dollars' worth of property was destroyed in what remained.

For some time after 1865 Virginia was under Federal military control as "District No. 1"; but on December 3, 1867, a convention, elected by the people, under an Act of the United States Congress, met and framed a new constitution, prohibiting slavery and accepting the results of the war; this was ratified by a popular vote, July 6, 1869, at which time members of a general assembly and State officers were also elected. The chosen governor was inaugurated September 21, 1869; the general assembly met October 5, 1869, and ratified the fourteenth and fifteenth amendments to the constitution of the United States; and on January 26, 1870, Virginia was readmitted to representation in Congress, and released from military control. (J. H*.)

---

[1] [Hampton Roads is properly the estuary through which the James, the Nansemond, and the Elizabeth rivers debauch into Chesapeake bay, and contains an area of nearly 60 sq. miles.—AM. ED.]

[2] [As early as 1556 Chesapeake Bay was known to the Spaniards as the Bay of Santa Maria, and an abortive expedition was sent thither to take possession of the adjacent country. See Scharf's *History of Maryland*, vol. i. pp. 21 *sq.*—AM. ED.]

VIRGINIA CITY, the county seat of Storey county, Nevada, U. S., and the largest and most important city of the State, is situated upon the steep rugged eastern slope of Mount Davidson, about 6300 feet above sea-level. A branch line connects it with the Central Pacific Railroad at Reno. Virginia City is built over the great Comstock lode, the mineral vein which has yielded probably more of the precious metals than any other single deposit in the world (see vol. xxiii. p. 867). With the varying fortunes of this lode the prosperity of Virginia City is intimately connected. It was founded in 1859, and in 1860 its inhabitants numbered 2345. In 1861 it received a city charter. It continued to increase until towards the end of that decade, when the falling off in the receipts from the mines caused a partial exodus from the town, and the census of 1870 showed only 7048 inhabitants. The discovery of the "great bonanza" in 1875 produced a return of prosperity, but this was but transient, and before the next census the city was again on the wane. In 1880 the census showed 10,917 inhabitants,—nearly half of foreign birth, and about 5 per cent. Chinese. Since the last census the population has, in all probability, not increased. The city is laid out rather irregularly, conforming to some extent to the surface of the mountain side. Some streets have been graded, at great expense, as it involved much rock cutting.

VIRGIN ISLANDS, a group of small West India Islands (see West Indies), about one hundred in number, for the most part uninhabited, extending eastward from Porto Rico, and lying between 17° and 18° 50′ N. lat., and 64° 10′ and 65° 30′ W. long. Their total area may be estimated at about 465 square miles, and their population at 67,000. For the most part they are rocky or sandy and barren, but the cultivable portions yield sugar, maize, coffee, cotton, indigo, and tobacco. Guinea grass grows abundantly on the hillsides, and the rich natural grass affords excellent pasturage; the forests include many useful trees, among which are mahogany and fustic. Fish are very plentiful along the coasts. The westerly portion of the group belongs to Spain, the central to Denmark, and the easterly to Great Britain. The chief of the Spanish islands are Culebra or Snake Island, and Bieques or Crab Island; they have in all an area of about 150 square miles, with a population of 2600. The Danish Virgin Islands, which include St. Thomas (*q.v.*), St. Croix (*q.v.*), and St. John, have a total of about 240 square miles, with about 34,000 inhabitants. The principal of the British portion of the group are Tortola, Anegada, and Virgen Gorda or Spanish Town, and Jost van Dyke (total area 57 square miles, and population 5287 in 1881, of whom more than one-half are in Tortola). They are subject to a lieutenant-governor, under the governor-in-chief of the Leeward Islands, and are governed by an administrative council of six elective and three non-elective members, presided over by the governor for the time being. In 1886 the revenue and expenditure were respectively £1448 [$7037.28] and £1676 [$8145.36]. The customs revenue was £823 [$3999.78], and there was no public debt. In the same year 1710 vessels entered, of 10,764 tons burden (exclusive of coasting trade), and 1779 vessels cleared, of 8444 tons; the total value of the imports was £3603 [$17,510.58] and of the exports £4103 [$19,940.58].

The Virgin Islands were discovered by Columbus on his second voyage, in 1494, and named Las Virgenes, in honor of St. Ursula and her companions. In 1666 the English established themselves on Tortola, which has ever since remained in their possession. In the 17th century the Virgin Islands were favorite resorts of the Buccaneers (*q.v.*). The Danish Islands of St. Thomas and St. John were taken by the British in 1801, but restored the following year. In 1807 they surrendered to the British, and continued in their hands till 1815, when they were again restored. The constitution of the British Virgin Islands was amended in 1854.

VISCONTI. See Milan, vol. xvi. p. 305.

VISCOUNT (Latin *vice-comes*), a titled rank of nobility, the fourth in the order of the British peerage, and consequently intervening between the dignities of earl and baron. The first English viscount, as that term now is used and understood, was John, Baron Beaumont, K.G., who, by letters patent dated 12th February, 1440, by Henry VI. was created Viscount Beaumont. The title *vice-comes*, however, existed in England certainly as early as the Domesday survey; and in those early times it was borne by a county officer, who was deputy to the *comes* or earl, in accordance with the feudal system, which knew no titles independent of offices. The *vice-comes*, whose title from the first may fairly be translated "viscount," and who acted in the absence of the earl, may be considered to have been identical with the functionary known by the English term "shire-reeve" or "sheriff," or, as we now should say, "high-sheriff." During the reigns of the Anglo-Norman monarchs this office of *vice-comes* was commonly hereditary; after awhile it was granted for several successive years to the same personage at the king's pleasure; and, finally, the modern practice obtained of appointing a new high-sheriff every year. A viscount is "Right Honorable," and is styled "My Lord." His wife, also "Right Honorable," is a "Viscountess," and is styled "My Lady." All their sons and daughters are "Honorable." The coronet first granted by James I. has on the golden circlet a row of fourteen small pearls set in contact, of which number in representations nine are shown. The scarlet parliamentary robe of a viscount has two and a half doublings of ermine.

VISHNU. See Brahmanism, vol. iv. p. 187.

VISTULA. See Poland, vol. xix. pp. 317–18.

VITALIANUS, bishop of Rome from 657 to 672, succeeded Eugenius I. and was followed by Adeodatus. In the monothelite controversy then raging he acted with cautious reserve, refraining at least from express condemnation of the *Typus* of Constans II. (see vol. xvi. p. 785). The chief episode in his uneventful pontificate was the visit of Constans to Rome; the pope received him "almost with religious honors," a deference which he requited by stripping all the brazen ornaments of the city—even to the tiles of the Pantheon—and sending them to Constantinople. Archbishop Theodore was sent to Canterbury by Vitalian.

VITEBSK, a government of western Russia, with Livonia and Pskoff on the N., Smolensk on the E., Moghileff, Minsk, and Vilna on the S., and Courland on the W., has an area of 17,440 square miles. Except on its southeastern and northern borders, where there are low hills, deeply eroded by the rivers, its surface is mostly flat, or slightly undulating, and more than a million of acres are occupied by immense marshes, with as many as 2500 small lakes. The Devonian limestones and red sandstones of which it is built up are covered with thick layers of Glacial and Lacustrine deposits,—the Glacial boulder-clay, with immense numbers of boulders, covering extensive areas. The rest consists of Lacustrine clays or sands. The soil is thus for the most part unproductive.

The Düna, or West Dwina, rises not far from the northeastern angle of the government, and flows through it, or along its southern boundary, for 530 miles. From its junction with the Kasplya, *i.e.*, for more than 450 miles, it is navigable; and, through a tributary, the Ulla, it is connected with the Dnieper by the Berezina Canal. The Mezha and Kasplya, tributaries of the Düna, are navigable in spring. The climate is relatively mild, the average yearly temperature at Vitebsk being 40° F. (January, 16.4°; July, 64.3°).

The population, 1,204,950 in 1884, is chiefly White Russian (61 per cent.) and Lettish (21 per cent.); Jews come next (10 per cent.). The Poles make only about 2.3 per cent. of the population, and there are moreover about 10,000 Germans in the northwest. The Great Russians number only a few thousands. Nearly two-thirds of the inhabitants are Orthodox or Raskolnik, the remainder being Catholics, Jews, or Lutherans.

Agriculture is the chief industry, but the yearly produce rarely suffices for the wants of the population, and corn has to be imported from Smolensk. Rye, oats, and potatoes are the chief crops, occupying about a third of the area. Flax is an important crop for export. Cattle-breeding is only moderately prosperous. Manufactures in 1884 occupied only some 3000 persons, and their aggregate production reached only about £788,700 [$3,833.082] (as against £84,000 [$408,240] in 1860); the most important branches are represented by distilleries, flour-mills, and tanneries. As a rule, the White Russian population of the villages is very poor, and great numbers of the peasants are compelled every year to leave their homes in search of work. Of domestic trades, the manufacture of wooden wares, as well as some boat-building and flax-combing, may be mentioned. The principal exports are flax, linseed, timber, and hides. There is a brisk water-traffic on the Düna by boats to Riga, Vitebsk loading-places contributing 1,128,500 cwts. (483,000 roubles [$391,910] value) loaded and 630,000 cwts. discharged in 1883.

Vitebsk is divided into twelve districts, the chief towns of which with populations in 1885, are Vitebsk (54,680), Drissa (3490), Dünaburg, a fortress on the Düna (69,030), Gorodok (5620), Lepel (6000), Lutsin (5460), Nevel (7310), Polotsk (19,130), Ryezhitza (10,150), Sebezh (3820), Surazh (5085), and Velizh (16,370).

VITEBSK, capital of the above government, stands on both banks of the Düna, on the railway from Smolensk to Riga, 345 miles west of Moscow. It is an old town, with decaying mansions of the old nobility, and dirty Jewish quarters, half of its 54,680 inhabitants being Jews. Its manufactures are insignificant, and the poorer classes support themselves by gardening, boat-building, and the flax trade, while the merchants carry on an active business with Riga in corn, flax, hemp, tobacco, sugar, and timber.

Vitebsk (Dbesk, Vitbesk, and Vitepesk) is mentioned for the first time in 1021, when it made part of the Polotsk principality. Eighty years later it became the chief town of a separate principality, and so continued until 1320, when, after having taken an active part in the internal wars of the Russian princes, it came under the dominion of the Lithuanians. In the 16th century it fell to Poland. Under the privileges given to the city by the Polish sovereigns it flourished, but it soon began to suffer from the wars between Russia and Poland, during which it was thrice taken by the Russians and burned. Russia annexed it finally in 1772.

VITELLIUS, **Aulus**, the ninth of the twelve Cæsars, and Roman emperor during the greater part of 69 A.D., was the son of Lucius Vitellius, who had been consul and governor of Syria under Tiberius, and distinguished for his gross and ridiculous flattery under Caius (Caligula) and Claudius, which the senate, who gave him a public funeral, recognized by a statue with the inscription "Pietatis immobilis erga principem." He was one of the intimate companions of Tiberius at Capreæ; he had driven chariots in the circus with Caius, had played dice with Claudius, had induced the young Nero to sing at a public entertainment, and had been a censor once and a consul three times. He had been governor of Africa, and had there, according to Suetonius (*Vitellius*, 5), acquitted himself creditably. Under Galba, to the general astonishment, he was chosen to command the army of Lower Germany, and here he made himself popular with his subalterns and with the soldiers by an outrageous prodigality and an excessive good nature, which soon proved quite fatal to order and discipline. Far from being an ambitious or scheming man, he was lazy and self-indulgent, fond of eating and drinking, and he was in fact drifted into empire by the promptings of Cæcina and Valens, commanders of two legions on the Rhine. Through these two men a military revolution was speedily accomplished, and early in 69 Vitellius was proclaimed emperor at Cologne, or, to speak more accurately, emperor of the armies of Upper and Lower Germany. In fact, he was never acknowledged as emperor by the entire Roman world, though at Rome the senate accepted him and decreed to him the usual imperial honors. But after all he was only emperor in name. It was noted as a bad omen that he received the title of supreme pontiff on the anniversary of the day of Allia, 390 B.C., on which Rome was all but utterly overthrown by the Gauls. His advance into Italy at the head of a licentious and ruffianly soldiery was as horrible and calamitous as civil war could possibly be; there was fighting and bloodshed within 7 miles of Rome, and amid riot and massacre and gladiatorial shows and extravagant feasting and a waste of seven millions of money (Tacitus, *Hist.*, ii. 95)[1] the capital of the empire was a scene of horror and infamy such as had never been witnessed in the most savage revolutions of past days. As soon as it was known that the armies of the East, Dalmatia, and Illyricum had declared for Vespasian, Vitellius, finding himself deserted by many of his adherents, was for resigning the title of emperor; so crestfallen was he, so dull and lethargic, that, to quote Tacitus (*Hist.*, iii. 63), "had not others remembered he had been an emperor, he would have forgotten it himself." On the entrance into Rome of Vespasian's troops he was dragged out of some miserable hiding-place, and, with his hands tied behind him, insulted, unpitied, driven to the fatal Gemonian stairs, and there struck down amid a shower of fierce eager blows. "Yet I was once your emperor," were the last, and, as far as we know, the noblest words of Vitellius. He perished thus miserably in his 57th year.

The *Histories* of Tacitus and the biography of Suetonius give us in full detail the story of Vitellius. In Merivale's *History of the Romans under the Empire* (chaps. 56, 57) the period is fully and vividly described.

VITERBO, a city of Italy, capital of a circondario in the province of Rome, lies 1200 feet above sea-level, on the Arcione, at the northwestern base of Monte Cimino (3450 feet), on the high road between Florence and Rome, 42 miles north-northwest of the latter city; a branch line (24¾ miles) connects it with the Attigliano station on the railway. It is picturesquely surrounded by luxuriant gardens, and enclosed by walls and towers, which date partly from the Lombard period. The streets are paved with large lava blocks, and the town has many handsome edifices, and some elegant fountains; among the latter may be mentioned the Fontana della Rocca by Vignola (1566). The cathedral, a fine basilica, with 13th-century restorations, contains the tombs of Popes Alexander IV., Clement IV., and John XXI. In 1271 it was the scene of the murder, on the steps of the high altar, during public worship, of Henry, son of Richard of Cornwall, by Guy de Montfort (see Dante, *Inf.*, xii. 118). In the sacristy is a Madonna with saints by Lorenzo di Viterbo. The old episcopal palace is a Gothic building of the 13th century, in which numerous conclaves have been held. The church of St. Rosa exhibits the embalmed body of that saint, a native of Viterbo, who died in her eighteenth year, after working various miracles and having distinguished herself by her invectives against Frederick II. (1251). San Francesco contains the tomb of Pope Adrian V., and has an important work by Sebastiano del Piombo; the Gothic cloisters of St. Maria della Verità are strikingly beautiful. The town-hall contains some Etrurian sarcophagi and a few good paintings. The inhabitants of Viterbo (15,279 in 1881) are chiefly dependent on agriculture; hemp is a specialty of the district, and tobacco and various grains are largely grown, as well as the olive and vine. There are in the vicinity numerous mineral springs; the warm sulphur spring of Bulicame, about 2 miles off, is alluded to by Dante (*Inf.*, xiv. 79).

Viterbo has sometimes, but very doubtfully, been identified with the *Fanum Voltumnæ*, where the general assembly of the Etruscans used to be held. It was fortified by the Lombards, and in the Middle Ages became a favorite papal residence. Popes Urban IV. (1261), Gregory X. (1271), John XXI. (1276), Nicholas III. (1277), and Martin IV.

---

[1] [Tacitus says here nine millions, or about $340,000 in money of the empire.—Am. Ed.]

(1281) were elected here, and it was at Viterbo that Alexander IV. (1261), Clement IV. (1268), Adrian V. (1276), and John XXI. (1277) died.

VITORIA, a town of Spain, capital of the Basque province of Alava, stands at a height of about 1750 feet above sea-level, on a small hill commanding the plain of Alava, 234 miles by rail north-northeast of Madrid. The oldest part of the town, the Campillo or Villa-Suso, occupies the top of the hill; some of the walls and towers by which it was formally defended still remain, but it is now almost deserted, and chiefly occupied by gardens. Below it is "Vitoria Antigua," with narrow tortuous lanes; on the lower level ground is the modern town, with wide streets, an arcaded market place, and shady promenades. The cathedral of St. Mary in the Campillo dates its foundation from 1181, and has some good Gothic arches, but has been considerably spoiled by late additions; the church of San Miguel also dates from the 12th century, but does not possess any features of special interest. Vitoria, from its favorable position, is an important centre of trade in wine, wool, horses, mules, and hardware; the chief industries are paper-making, carriage-building, cabinet-making, tanning, and the manufacture of earthenware. The population within the municipal boundaries in 1877 was 25,039.

Though an obscure village seems to have occupied the site from an early period, the existence of Vitoria as a town dates from 1181, when Sancho the Wise of Navarre granted a "fuero" similar to that of Logroño, and fortified the place. A decisive victory was here gained by the Anglo-Spanish army under Wellington over the French under Joseph Bonaparte and Jourdan on June 21, 1813.

VITRE, a town of France, chef-lieu of an arrondissement in the department of Ille-et-Vilaine, stands on a hill rising from the left bank of the Vilaine, 24 miles east of Rennes by the railway to Paris. The town has preserved as many features of the Middle Ages as any in France, and viewed from the north its feudal aspect is striking. The streets are formed of confused masses of wooden houses, full of projections and curves, covered with coarse slate overgrown with moss and lichen, and are bordered by covered galleries on a level with the ground, out of which dark shops open. Most of the curious houses, ornamented with statuettes and sculptures, are older than the first half of the 17th century. Only one vault remains of the original castle, founded towards the end of the 11th century; the rest was rebuilt in the 14th and 15th centuries (the best period of Breton military architecture in Brittany), and all has been recently restored. It is now occupied by a prison, a museum of natural history and painting, and the town library (6000 volumes). In the court is the former collegiate church, some of it older than the 12th century. The church of Notre Dame, formerly a priory of the abbey of St. Mélaine of Rennes, dates from the 15th and 16th centuries. An outside stone pulpit is a fine example of 16th-century sculpture. Parts of the ramparts are still standing, and other parts are built into the houses of the town. There is a well-wooded botanical garden, and the remains of a castle destroyed at the Revolution. The chief articles of trade are cloth, hosiery, and thick clothing made of goats' skins. The chateau of Les Rochers, celebrated through Madame Sévigné, stands 3 miles from the town. The population in 1886 was 8957 (commune 10,447).

Vitré was formerly a Breton barony, and belonged in the 10th century to the younger branch of the counts of Rennes. In 1295 it passed to Guy IX. baron of Laval, on his marriage with the heiress, and afterwards successively belonged to the families of Rieux, Coligny, and La Trémoille. The town was seized by Charles VIII. in 1488. Protestantism spread under the rule of the houses of Rieux and Coligny; Vitré became a Huguenot stronghold; and a Protestant church was established, which was not suppressed till the revocation of the edict of Nantes in 1685. Mercœur, the head of the members of the League in Brittany, besieged the town in vain for five months in 1589, and was forced to withdraw by the army under the Prince de Dombes. The estates of Brittany, over which the barons of Vitré and of Léon alternately presided, met here several times, and Madame de Sévigné gives interesting details of such an occasion. Vitré was the birthplace of Pierre Landais, the favorite minister of Francis II., duke of Brittany (hanged in 1485), of his nephew Cardinal Guibé, and of Bertrand d'Argentré, jurist and the historian of Brittany.

VITRIFIED FORTS is the name given to certain rude stone enclosures whose walls bear traces of having been subjected to the action of fire. They are generally situated on elevated hills, which occupy strong and easily defended positions. Their form is irregular, and seems to have been determined rather by the contour of the flat summits which they enclose than by any definite architectural plan. The walls vary in size, some being comparatively small, while a few are upwards of 12 feet high, and are so broad that they present the appearance of huge embankments. Weak and exposed parts in the defence are strengthened by double or triple walls, and occasionally vast lines of ramparts, composed of large blocks of unhewn and unvitrified stones, are drawn around the fortified hills at some distance from the vitrified centre. No lime or cement has been found in any of these structures, but all of them present the peculiarity of being more or less consolidated by the fusion of the rocks of which they are built. This fusion, which has been caused by the application of intense heat, is not equally complete and regular in the various forts, or even in the walls of the same fort. In some cases the stones are only partially melted and calcined; in others their adjoining edges are fused so that they are firmly cemented together; in many instances pieces of rock are enveloped in a glassy enamel-like coating which binds them into a uniform whole; and at times, though rarely, the entire length of the wall presents one solid mass of vitreous substance.

Since John Williams—one of the earliest of British geologists, and author of *The Mineral Kingdom*—first described, in 1777, these singular ruins, about fifty examples have been discovered in different parts of Scotland. The most remarkable are Dun Mac Uisneachain, the ancient Beregonium, north of Oban; Tap o' Noth, in Aberdeenshire; Craig Phadraic and Dun Dhardhail, in Inverness; Knockfarrail, near Strathpeffer; Dun Creich, in Sutherland; Findhaven, near Aberlemno; Barryhill, in Perthshire; Laws, near Dundee; Dun Gall and Burnt Island, in Buteshire; Anwoth, in Kirkcudbright; and Cowdenknowes, in Berwickshire. Dun Mac Uisneachain is the largest in area, being 250 yards long by 50 yards broad. The strongest and most cyclopean is the Tap o' Noth: here the walls are about 8 feet high, and between 20 and 30 feet thick. In Dun Mac Uisneachain, Barryhill, and Laws the remains of small rectangular huts or dwellings have been found.

For a long time it was supposed that these forts were limited in their range to Scotland; but they are now known to exist in Londonderry and Cavan, in Ireland; in Upper Lusatia, Bohemia, Silesia, Saxony, and Thuringia; in the provinces on the upper banks of the Rhine, especially in the neighborhood of the Nahe; in the Ucker Lake, in Brandenburg, where the walls are formed of burnt and smelted bricks; and in several places in France, such as Châteauvieux, Peran, La Courbe, Saint Suzanne, Puy de Gaudy, and Thauron. They have not been found in England or Wales; and Worsaae, Herbst, Rygh, Hildebrand, and Stephens assert that they do not exist in Denmark or in Scandinavia.

All the examples yet described present a general similarity in form and structure. In some of the Continental forts the vitrified walls are supported by masses of unvitrified stone built up on each side. This, in all probability, constituted an essential feature in the Scottish forts. Except on the hypothesis of buttresses of a similar kind, it is impossible to explain the vast quantities of loose stones which are found both inside and outside many of the vitrified walls.

The method by which the fusion of such extensive fortifications was produced has always excited much interest and conjecture. Williams, when he first directed attention to the subject, maintained that the builders of the forts, whoever they were, found out, either during the process of smelting bog-ore, or whilst offering sacrifices, the power of fire in vitrifying stone, and that they improved upon this discovery by using it for the purpose of cementing and strengthening their strongholds. This view has been keenly controverted, and other theories have been suggested. It has been held that the vitrified summits were not forts at all, but the craters of extinct volcanoes (West, Pennant, and Cordiner), an hypothesis long since abandoned as unscientific; that the vitrified summits are not so much vitrified forts as vitrified sites, and that the vitrescence was produced by beacon fires lighted during times of invasion, or by bonfires kindled on hill tops in religious celebrations (Sir George Mackenzie, Dr. S. Hibbert, and Principal Daniel Wilson); and, lastly, that if they were forts they must have originally been built of wood and stone, and that their present vitrified appearance is not due to design, but to their being set on fire by a besieging enemy (A. Fraser Tytler, Forbes Leslie, Von Cohausen, and Dr. Joseph Anderson). The theory of Williams—which has, with modifications, been accepted by all the principal British and Continental authorities, such as MacCulloch, Hugh Miller, Virchow, Schaaffhausen, Thuot, and Montaiglon—is likely to hold the field. It is supported by the following facts:

(1) The idea of strengthening walls by means of fire is not singular, or confined to a distinct race or area, as is proved by the burnt-earth enclosure of Aztalan, in Wisconsin, and the vitrified stone monuments of the Mississippi valley. (2) Many of the Primary rocks, particularly the schists, gneisses, and traps, which contain large quantities of potash and soda, can be readily fused in the open air by means of wood fires,—the alkali of the wood serving in some measure as a flux. (3) The walls are chiefly vitrified at the weakest points, the naturally inaccessible parts being unvitrified. (4) When the forts have been placed on materials practically infusible, as on the quartzose conglomerates of the Old Red Sandstone, as at Craig Phadraic, and on the limestones of Dun Mac Uisneachain, pieces of fusible rocks have been selected and carried from a considable distance to the top. (5) The vitrified walls of the Scottish forts are invariably formed of small stones which could be easily acted upon by fire, whereas the outer ramparts, which are not vitrified, are built of large blocks. (6) Many of the Continental forts are so constructed that the fire must have been applied internally, and at the time when the structure was being erected. (7) Daubrée, in an analysis which he made on vitrified materials taken from four French forts, and which he submitted to the Academy of Paris in February, 1881, found the presence of natron in such great abundance that he inferred that sea-salt was used to facilitate the original fusion. (8) In Scandinavia, where there are hundreds of ordinary forts, and where for centuries a system of signal fires was enforced by law, no trace of vitrifaction has yet been detected.

A great antiquity has been assigned to vitrified forts, but without sufficient proof. Articles of bronze and iron have been found in the Scottish forts, while in Puy de Gaudy a Roman tile has been discovered soldered to a piece of vitrified rock. In a few of the German forts Prof. Virchow found some of the short logs of oak used as fuel in vitrifying the walls, and he concluded from the evenness of their cut surfaces that iron and not stone implements must have been used. These results indicate that these structures are the products of a high civilization, and were possibly in use as late as the early centuries of our era. ' It has been suggested that they were built as temporary refuges against the invasions of the Norsemen in Europe. There is much in the situation and character of the forts which favors this supposition. This is especially the case with reference to the Scottish forts. Here the vitrified summits are invariably so selected that they not only command what were, as we learn from the sagas, the favorite landing places of the vikings, but are the best natural defences against attacks made from the direction of the sea-coast. In Saxony and Lusatia the forts are known as *Schwedenburgen*, and in the Highlands of Scotland as the fortresses of the *Feinne*—designations which also seem to point to an origin dating back to the times of the vikings.

It may be interesting, as throwing light on the influence of high temperature on rocks, to notice some of the forms exhibited by the fused substances. Schistose gneiss is resolved into a kind of green glass; mica is converted into a gray glassy stone of great hardness; quartz is reduced to the condition of pumice; trap rock becomes glazed like bottle glass; sandstone is transformed into a compact quartzite; and the felspar of granite is changed into coarse porcelain. Some of the materials have assumed, probably during the process of cooling, the prismatic structure, with four or six sides; while others, owing to the iron peroxide being reduced, have become distinctly magnetic.

The following are some of the more important treatises and references; Williams, *An Account of some Remarkable Ancient Ruins;* A. Frazier Tytler, *Edin. Phil. Trans.*, vol. ii.; Sir George Mackenzie, *Observations on Vitrified Forts;* Hibbert, *Arch. Scot.* vol. iv.; MacColloch, *Highlands and Western Islands*, vol. i.; Miller, *Rambles of a Geologist*, chap. ix.; Wilson, *Archæology*, and *Prehistoric Annals*, vol. ii.; J. H. Burton, *History of Scotland*, vol. i.; R. Angus Smith, *Loch Etive and the Sons of Uisneach;* Anderson, *Scotland in Pagan Times;* C. VITRIOL, a name formerly and sometimes still given to sulphuric acid and to certain sulphates (see SULPHUR, vol. xxii. pp. 669–70). Oil of vitriol is concentrated sulphuric acid. Blue vitriol is sulphate of copper; green vitriol is sulphate of iron (copperas, ferrous sulphate); and white vitriol, sulphate of zinc.

VITRUVIUS,[1] a Roman architect and engineer, whose full name was MARCUS VITRUVIUS POLLIO, the author of a very celebrated work on architecture. Nothing is known about his personal history, except what can be gathered from incidental remarks in his own writings. Owing to the discovery of a number of inscriptions relating to the Gens Vitruvia at Formiæ in Campania (Mola di Gaeta), it has been suggested that he was a native of that city, and he has been less reasonably connected with Verona on the strength of an existing arch of the 3d century, which is inscribed with the name of a later architect of the same family name—"Lucius Vitruvius Cerdo, a freedman of Lucius." From Virtruvius himself we learn that he was appointed, in the reign of Augustus, together with three others, a superintendent of *balistæ* and other military engines, a post which, he says, he owed to the friendly influence of the emperor's sister, probably Octavia (*De Architectura*, i. pref.). In another passage (v. 1) he describes a basilica and adjacent ædes Augusti, of which he was the architect. From viii. 3 it has been supposed that he had served in Africa in the time of Julius Cæsar, probably as a military engineer, but the words will hardly bear this interpretation. He speaks of himself as being low in stature, and at the time of his writing bowed down by age and ill-health (ii. pref.). He appears to have enjoyed no great reputation as an architect, and with philosophic contentment, records that he possessed but little fortune. Though a great student of Greek philosophy and science, he was unpracticed in literature, and his style is very involved and obscure. To a great extent the theoretical and historical parts of his works are compiled from earlier Greek authors, of whom he gives a list at i. 1 and viii. 3. The practical portions, on the contrary, are evidently the result of his own professional experience, and are written with much sagacity, and in a far clearer style than the more pedantic chapters, in which he gives the somewhat fanciful theories of the Greeks. Some sections of the latter, especially those on the connection between music and architecture, the scale of harmonic proportions, and the Greek use of bronze vases to reverberate and strengthen the actors' voices in the theatre, are now almost wholly unintelligible.

---

[1] The references in this article follow the divisions into books and chapters adopted in the more recent German editions.

The *De Architectura* is divided into ten books, each with a preface, in which occur most of the personal facts about himself. It is dedicated to Augustus, and that fact is really all that is known with regard to the date at which Vitruvius lived, though many attempts have been made to gather more minute indications from the internal evidence of his writings: for example, the omission of any mention of the Pantheon in Rome has been taken as an argument to show that he wrote before it was built in 27 B.C. This, however, and other arguments of the same kind are obviously of but little weight. Vitruvius's name is mentioned by Frontinus in his work on the aqueducts of Rome; and most of what Pliny says (*H. N.*, xxxv. and xxxvi.) about methods of wall-painting, the preparation of the stucco surface, and other practical details in building is taken almost word for word from Vitruvius, especially from vi. 1, though without any acknowledgment of the source.

From the early Renaissance down to a comparatively recent time the influence of Vitruvius's treatise has been remarkably great. Throughout the period of the classical revival Vitruvius was the chief authority studied by all architects, and in every point his precepts were accepted as final. In some cases a failure to understand his meaning led to curious results; for example, the mediæval custom, not uncommon in England, of placing rows of earthenware jars under the floor of the stalls in church choirs appears to have been an attempt to follow out Vitruvius's remarks about the advantages of placing bronze vases round the auditorium of theatres. Bramante, Michelangelo, Palladio, Vignola, and earlier architects were careful students of Vitruvius's work, which through them has largely influenced the architecture of almost all European countries down to the present century, a very remarkable instance of the success and influence of a book being actively redeveloped a very long time—about fifteen centuries—after its author's lifetime. There is no reason to suppose that the book was either popular or influential among the ancient Romans, and yet in more modern times its influence has been unbounded. Its archæological value is very great, as without it we should find it very difficult to understand the uses of the various parts of such houses as those at Pompeii, and many interesting details with regard both to construction and design would have remained unintelligible.

Bk. i. opens with a dedication to Augustus. C. 1 is on the science of architecture generally, and the many different branches of knowledge with which the trained architect ought to be acquainted, viz., grammar, music, painting, sculpture, medicine, geometry, mathematics, and optics; c. 2 is on the general principles of architectural design; c. 3 on the considerations which determine a design, such as strength, utility, beauty, and the like; c. 4 on the nature of different sorts of ground for sites; c. 5 on walls of fortification; c. 6 on aspects towards the north, south, and other points; c. 7 on the proper situations of temples dedicated to the various deities. Bk. ii. relates to materials (preface about Dinocrates, architect to Alexander the Great). C. 1 is on the earliest dwellings of man; c. 2 on systems of Thales, Heraclitus, Democritus, etc.; c. 3 on bricks; c. 4 on sand; c. 5 on lime; c. 6 on pozzolana; c. 7 on kinds of stone for building; c. 8 on methods of constructing walls in stone, brick, concrete, and marble, and on the materials for stucco; c. 9 on timber, time for felling it, seasoning, etc.; and c. 10 on the fir trees of the Apennines. Bk. iii., on styles, has a preface on ancient Greek writers. C. 1 is on symmetry and proportion; c. 2 on various forms of Greek temples, *e.g.*, in antis, prostyle, peripteral, dipteral, hypæthral;[1] c. 3 on intercolumniation—pycnostyle, systyle, eustyle, etc.; c. 4 on foundations, steps, and stylobates; c. 5 on the Ionic order, its form and details. Bk. iv., on styles and orders, has a preface to Augustus on the scope of the work. The subjects of its nine chapters are—(1) the Corinthian, Ionic, and Doric orders; (2) the ornaments of capitals, etc.; (3) the Doric order; (4) proportions of the cella and pronaos; (5) sites of temples; (6) doorways of temples and their architraves; (7) the Etruscan or Tuscan order of temples; (8) circular temples; (9) altars. Bk. v., on public buildings, has a preface on the theories of Pythagoras, etc. Its twelve chapters treat (1) of fora and basilicæ, with a description of his own basilica at Fanum; (2) of the adjuncts of a forum (ærarium, prison, and curia); (3) of theatres, their site and construction; (4) of laws of harmonics; (5) of the arrangement of tuned bronze vases in theatres for acoustic purposes; (6) of Roman theatres; (7) of Greek theatres; (8) of the selection of sites of theatres according to acoustic principles; (9) of porticus and covered walks; (10) of baths, their floors, hypocausts, the construction and use of various parts; (11) of palæstræ, xysti, and other Greek buildings for the exercise of athletes; (12) of harbors and quays. Bk. vi. is on sites and planning, and the preface treats of various Greek authors. C. 1 is on selection of sites; c. 2 on the planning of buildings to suit different sites; c. 3 on private houses, their construction and styles, the names of the different apartments; c. 4 on the aspects suited for the various rooms; c. 5 on the various sorts of buildings fitted for special positions; c. 6 on farms and country houses; c. 7 on Greek houses and the names of various parts; c. 8 on construction of houses in wood, stone, brick, or concrete. Bk. vii., mostly on methods of decoration, has a preface (as usual) on the opinions of ancient Greek writers, with lists of Greek sculptors, architects, and writers on architecture, and of Roman architects. C. 1 has for its subject pavements and roads, their construction, mosaic floors; c. 2 is on white stucco for walls (*opus albarium*); c. 3 on concrete vaults, gypsum mouldings, stucco prepared for painting; c. 4 on building of hollow walls to keep out the damp, wall decoration by various processes; c. 5 on methods and styles of wall painting, the debased taste of his time; c. 6 on fine stucco made of pounded marble,—three coats to receive wall paintings; c. 7 on colors used for mural decoration; c. 8 on red lead (*minium*) and mercury, and how to use the latter to extract the gold from worn-out pieces of stuff or embroidery; c. 9 on the preparation of red lead and the method of encaustic painting with hot wax, finished by friction; cc. 10–14 on artificial colors—black, blue, purple; c. 10 white lead and *ostrum*, *i.e.*, murex purple, and imitations of murex dye. Bk. viii. is on hydraulic engineering, and the preface on theories of the ancients. C. 1 treats of the finding of good water, its quality according to the soil it runs through; c. 2 of rain-water and rivers—rivers in various countries; c. 3 of hot springs, mineral waters with an account of the chief medicinal springs of the world; c. 4 of selection of water by observation and experiment; c. 5 of instruments for levelling used by aqueduct engineers; c. 6 of construction of aqueducts, pipes of lead, clay, etc., cisterns, fountains, poisoning from lead pipes, hydraulic cement, settling tanks, and other valuable matter on the subject of water supply. Bk. ix. is on astronomy. The preface treats of Greek sciences, geometry, the discovery of specific gravity by Archimedes, and other valuable discoveries of the Greeks, and of Romans of his time who have vied with the Greeks—Lucretius in his poem *De Rerum Natura*, Cicero in rhetoric, and Varro in philology, as shown by his *De Lingua Latina*.[2] The subjects of the eight chapters are (1) the signs of the zodiac and the seven planets; (2) the phases of the moon; (3) the passage of the sun through the zodiac; (4) and (5) various constellations; (6) the relation of astrological influences to nature; (7) the mathematical divisions of the gnomon; (8) various kinds of sun-dials and their inventors. Bk. x. is on machinery, with a preface concerning a law at ancient Ephesus compelling an architect to complete any public building he had undertaken; this, he says, would be useful among the Romans of his time.[3] The chapters are—(1) on various machines, such as scaling-ladders, windmills, etc.; (2) on windlasses, axles, pulleys, and cranes for moving heavy weights, such as those used by Chersiphron in building the great temple of Diana at Ephesus, and on the discovery by a shepherd of a quarry of marble required to build the same temple; (3) on dynamics; (4) on machines for drawing water; (5) on wheels for irrigation worked by a river; (6) on raising water by a revolving spiral tube; (7) on the machine of Ctesibius for raising water to a height; (8) on a very complicated water engine, the description of which is not intelligible, though Vitruvius remarks that he has tried to make the matter clear; (9) on machines with wheels to register the distance travelled, either by land or water; (10) on the construction of *scorpiones* for hurling stones; (11) and (12) on *balistæ* and catapults; (13) on battering rams, and other machines for the attack of a fortress; (14) on shields (*testudines*) to enable soldiers to fill up the enemy's ditches; (15) on other kinds of *testudines;* (16) on machines for defence, and examples of their use in ancient times.

---

[1] The excavations made in 1887 have shown that Vitruvius was right in describing the great temple of Olympian Zeus at Athens as being octastyle. The previously almost universal opinion that it was decastyle had led to the needless theory that the passage containing this statement was corrupt.

[2] Vitruvius names Cicero and Lucretius as "post nostram memoriam nascentes."

[3] The architect being at that time also the contractor.

The first MS. of the *De Architectura* which attracted much attention was a fine codex on vellum preserved in the Benedictine monastery of Monte Cassino. The first printed edition is that issued in Rome by George Herolt about 1485–86, but without indication of place or date; it is a small folio with thirty-four lines to the page, and has neither signatures, catchwords, nor numbering of the leaves. It was edited by J. Sulpicius, and with it is printed Frontinus *De Aquæductibus;* this second work occurs as an addition in many early editions of Vitruvius, of which a very large number were printed at various places in Italy within a few years after the publication of the *editio princeps.*[1] On the whole the best edition of Vitruvius's text is that edited by Schneider, Leipsic, 1807, 3 vols. 8vo, with good notes, but no plates. An immense number of translations have also been published in most European languages—the first Italian translation at Como in 1521; French, at Paris in 1547; German, at Nuremberg in 1548; and the first English translation in London in 1692. The best English translation is that of Gwilt, 1826, improved edition, 1860. That of Wilkins (1812) is merely a fragment of some of the books, but it is copiously illustrated with engraved plates.

The name of Vitruvius has been given to several handsome works on modern architecture, such as Campbell, *Vitruvius Britannicus*, London, 1715–71, a series of illustrations of the chief buildings of the 18th century in England, including many works of the brothers Adam; one of these brothers, William Adam, produced a similar work illustrating the buildings which he had designed for Scotland, of which he was a native, under the title of *Vitruvius Scoticus*, Edinburgh, 1790. Thurah, *Le Vitruve Danois*, Copenhagen, 1746–49, is a similar collection of modern buildings in Denmark.

The biographies of Vitruvius as usually published are very untrustworthy, and contain many statements which rest upon no authority whatever. (J. H. M.)

VITTORIA, an inland town of Sicily, in the Italian province of Syracuse, about 18 miles by road east-southeast from Terranova, stands in the midst of a rich vine and olive district, which also produces silk, rice, and honey. The population in 1881 was 21,755. It is quite a modern town,—founded towards the beginning of the 17th century. The principal church (San Giovanni) dates from 1854.

VITUS, St., according to the Roman Breviary, while still a very young boy, had been baptized without the knowledge of his father, who, on learning this, spared no effort to bring about his return to paganism. After other severe measures had been tried in vain he was delivered to Valerian to be scourged, but even this had no effect, and he was handed back to his father. Admonished by an angel, Vitus, accompanied by Modestus and Crescentia, by whom he had been brought up, now took refuge abroad, where his fame for sanctity became so great that he was summoned by Diocletian to heal his child, who was grievously vexed with a devil. Successful in this he was urged by the ungrateful emperor to worship the pagan deities, and on his refusal was cast into prison. Along with Modestus and Crescentia he was sentenced to be plunged into a cauldron of molten lead, resin, and pitch, but here their experience was that of the three Hebrew children. Next they were cast before the lion, but the wild beast fawned upon them and licked their feet. Finally they were torn limb from limb. The three are commemorated on June 15. The more extended legend of St. Vitus relates that, on one occasion when he had been shut up in a dungeon, his father looking through a chink in the door beheld him dancing with seven beautiful angels; so dazzled was he by the sight that he became blind, and recovered only through the intercession of his son. St. Vitus is accordingly the patron saint of dancers and actors, and is invoked against the disease known as St. Vitus's Dance (*q.v.*). He is the patron of Saxony, Bohemia, and Sicily, and throughout Germany ranks as one of the fourteen "Nothhelfer" of the church.

VIVARINI, the surname of a family of painters of Murano (Venice), who produced a great quantity of work in Venice and its neighborhood in the 15th century, leading on to that phase of the school which is represented by Carpaccio and the Bellinis.

Antonio Vivarini was probably the earliest of this family. He came from the school of Andrea da Murano, and his works show the influence of Gentile da Fabriano. The earliest known date of a picture of his, an altar-piece in the Venetian academy, is 1440; the latest, in the Lateran museum, 1464. He worked in company with a certain "Joannes de Alemania." By some writers Joannes has been regarded as himself a Vivarini, but this appears improbable: no trace of him exists of a date later than 1447. After 1447 Antonio painted either alone or in combination with his younger brother Bartolommeo. The works of Antonio are well drawn for their epoch, with a certain noticeable degree of softness, and with good flesh and other tints. Three of his principal paintings are the Virgin Enthroned with the Four Doctors of the Church, the Coronation of the Virgin, and Sts. Peter and Jerome. The first two (in which Joannes co-operated) are in the Venetian academy, the third in the London National Gallery.

Bartolommeo Vivarini is known to have worked from 1450 to 1499. He learned oil-painting from Antonello da Messina, and is said to have produced, in 1473, the first oil picture done in Venice. This is in the church of Sts. John and Paul,—a large altar-piece in nine divisions, representing Augustine and other saints. Most of his works, however, including one in the National Gallery, are in tempera. His outline is always hard, and his color good; the figures have much dignified and devout expression. As "vivarino" means in Italian a goldfinch, he sometimes drew a goldfinch as the signature of his pictures.

Luigi or Alvise Vivarini painted in 1490 and on to 1505. It has sometimes been supposed that, besides the Luigi who was the latest of this pictorial family, there had also been another Luigi who was the earliest, this supposition being founded on the fact that one picture is signed with the name, along with the date 1414. There is good ground, however, for considering this date to be a forgery of a later time. The works of Luigi show an advance on those of his predecessors, his best work being one which he executed for the Scuola di S. Girolamo in Venice, representing the saint caressing his lion, and some monks decamping in terror. The architecture and perspective in this work are superior. Other works by Luigi are in Treviso and in Milan.

VIVES, Juan Luis (or **Ludovicus**) (1492–1540), a well-known scholar of the third and fourth decades of the 16th century, was born at Valencia, in Spain, in March, 1492. He studied at Paris and Louvain, ultimately becoming professor of humanity at the latter university. At the instance of his friend Erasmus he prepared an edition of Augustine's *De Civitate Dei*, which was published in 1522 with a dedication to Henry VIII. of England. Soon afterwards he was invited to England and appointed tutor to the Princess Mary, for whose benefit he wrote *De Ratione Studii Puerilis Epistolæ Duæ.* While in England he resided a good deal at Oxford, where he was made doctor of laws and lectured on philosophy. Having openly declared himself against the king's divorce, he lost the royal favor and was thrown into prison, where he remained for six months. On his release he went to Spain and afterwards to the Low Countries, finally settling in Bruges, where he married and devoted himself to the composition of his numerous works, which were chiefly directed against the scholastic philosophy and the preponderant authority of Aristotle. He died on May 6, 1540.

---

[1] One of the earliest commentators on Vitruvius was the monk-architect Fra Giocondo, a man of extraordinary talent (see Verona).

A complete edition of his works was published at Basel in 1555 (2 vols. fol.), and another at Valencia in 1782.

VIZAGAPATAM, a British district of India, in Madras presidency, lying between 17° 14′ 30″ and 18° 58′ N. lat. and 82° 19′ and 83° 59′ E. long., with an area of 3477 square miles. Including the Jáipur and Vizianagram zamindaries, which are under British administration, the area is 17,380 square miles. Vizagapatam is bounded on the N. by Ganjam district, on the E. by Ganjam and the sea, on the S. by the sea and Godávari district, and on the W. by the Central Provinces. It is a beautiful, picturesque, and hilly country, forming part of the large extent of shore known as the Orissa coast, but for the most part it is unhealthy. The surface of the country is generally undulating, rising towards the interior, and crossed by streams, which are dry except during the rainy season. The main portion is occupied by the Eastern Gháts. The slopes of these mountains are clothed with luxuriant vegetation, amid which rise many tall forest trees, while the bamboo grows profusely in the valleys. The drainage on the east is carried by numerous streams direct to the sea, and that to the west flows into the Godávari through the Indravati or through the Sabari and Sillar rivers. To the west of the range is situated the greater portion of the extensive zamindari of Jáipur, which is for the most part very hilly and jungly. The north and northwest of the district is also mountainous. In the extreme north a remarkable mass of hills, called the Nimgiris, rise to a height of 4972 feet, and these are separated by valleys of not more than 1200 feet from the neighboring ranges of Gháts. The plain along the Bay of Bengal is exceedingly rich and fertile. It is described as a vast sheet of cultivation, green with rice fields and gardens of sugar-cane and tobacco. There are great varieties of climate in the district. Along the coast the air is soft and relaxing, the prevailing winds being southeasterly. The average annual rainfall at Vizagapatam exceeds 40 inches.

The census of 1881 returned the population of the district, exclusive of the agency tracts, at 1,790,468 (males 897,116, females 893,352). Including the Jaipur and Vizianagram dependencies, the total population of the district was 2,485,141 (males 1,254,850, females 1,230,291), of whom 2,460,474 were Hindus, 20,403 Mohammedans, and 3410 Christians. There are five towns with populations of more than 10,000 viz: VIZAGAPATAM and VIZIANAGRAM (*q.v.*); Anakapalle, 13,341; Bobbili, 14,943; and Salur, 11,856. The chief crops are rice, which is the staple product of the country, and sugar. The cultivation of indigo is also successfully carried on. The actual area under cultivation in 1885-86 amounted to 168,559 acres, besides 10,833 acres of forests. The gross revenue of the district in 1885-86 was £201,699 [$980,257.14], of which the land yielded £139,200 [$676,512]. There are few industries, the principal being cotton cloths and the beautiful fancy wares of Vizagapatam towns. On the dissolution of the Mughal empire Vizagapatam occupied a portion of the territory known as the Northern Circars, which were ceded to the East India Company by treaty in 1768. On the introduction of the permanent settlement in 1802 it was formed into a separate collectorate, and since then several changes have been made in its administration.

VIZAGAPATAM, a municipal and seaport town, the administrative headquarters of the above district, with a population in 1881 of 30.291. It lies on a small bay, the south extremity of which is bounded by a promontory known as the Dolphin's Nose, and its northern extremity by the suburb of Waltair. The town or fort, as it is called, is separated from the Dolphin's Nose by a small river, which forms a bar where it enters the sea, but is passable for vessels of 300 tons during spring tides. Vizagapatam is the residence of a Roman Catholic vicar apostolic. It contains some good streets, has a handsome hall, library, and reading-room, an excellent hospital and dispensary, and maintains a great many schools. The principal exports are grain and sugar, and the principal industries of the town are elk horn and ivory knick-knacks and gold and silver filigree work.

VIZIADRUG, or GHERIA, a port in Ratnágiri district, Bombay presidency, India, about 30 miles south of Ratnágiri town and 170 miles south of Bombay city, in 16° 33′ 40″ N. lat and 73° 22′ 10″ E. long. It is one of the best harbors on the western coast of India, being without any bar, and may be entered in all weathers; even to large ships it affords safe shelter during the southwest monsoon. The chief interest of the place centres in its fort, which is one of the strongest Mohammedan fortresses in the Concan, and rises grandly about 100 feet above the river.

About 1698 the pirate chief Angria made Viziadrug the capital of a territory stretching for about 150 miles along the coast, and from 30 to 60 miles inland. The fort surrendered to the English fleet in 1756, and was given over to the peshwá. In May, 1818, an unsuccessful attempt was made to take Viziadrug, but the whole of the district of Ratnágiri having now passed into the hands of the British, the fortress surrendered in June.

VIZIANAGRAM, one of the most ancient and extensive estates of zamindaries in India, included in the Vizagapatam district of the Madras presidency, with an area of about 3000 square miles, and a population (1881) of 844,168. The chief town, Vizianagram, had in 1881 a population of 22,577.

The zamindari first came under the charge of the English authorities in 1817, with a very heavy debt, but it was restored to the rájá five years afterwards clear of all incumbrances. It again came under their charge in 1827, during a minority, but on the rájá's coming of age it was again restored with a surplus.

VIZIER (Arabic *Wazîr*), literally the "burden bearer" of the sovereign. The office of vizier, which spread from the Arabs to the Persians, Turks, Mongols, and other Oriental peoples, arose under the first Abbasid caliphs, and took shape under their great ministers the Barmecides (see vol. xvi. pp. 602, 604–605). The vizier stood between sovereign and subjects, representing the former in all matters touching the latter. This withdrawal of the head of the state from direct contact with his people was unknown to the Omayyads, and was certainly an imitation of Persian usage; it has even been plausibly conjectured that the name is but the Arabic adaptation of a Persian title.[1] It appears, however, in the Koran (xx. 30, xxv. 37), where Aaron is called the *wazîr* of Moses, and these passages are appealed to by Arabic writers as giving divine sanction to the institution. The title of *wazîr* was often given to ministers of a special department, such as the treasury or the police, but *the wazîr* (the grand vizier, as Europeans say) bore the whole burden of the state, and, although his position was absolutely uncertain, depending on the mere will of the sovereign, his power was unlimited. His place was one of dizzy grandeur but of extreme difficulty. He was expected to be able to answer all questions, realize every wish of the caliph, keep the coffers of the state full, and yet find time to cultivate the personal favor of the sovereign by the display of social gifts. Such were the Barmecide viziers, the brilliant type of which all subsequent Oriental ministers are more or less imperfect copies. Ultimately under the caliph Râḍî the grand vizier gave way to a mayor of the palace called the *amîr al-omarâ*, but the old office and title were continued at the courts of the princes who rose on the decline of the caliphate. In Spain, where the chamberlain (*ḥâjib*) was the greatest officer of state, the title of *wazîr* was given to governors of towns, and in this sense the word was the parent of the Spanish *alguazil*.

[1] See Lagarde, *Armenische Studien*, p. 147, and Nöldeke's translation of Tabari, pp. 53 n, 444 n.

VIZZINI, an inland town of Sicily, in the Italian province of Catania, 39 miles E.N.E. of Terranova and 34 miles W.N.W. of Syracuse, is a prosperous country place of 13,966 inhabitants (1881). It has several churches (S. Gregorio, Minori Osservanti, S. Maria de' Greci), with pictures of some artistic or antiquarian interest.

VLACHS. Vlach, otherwise written Wallack, is a general name for all the members of the Latin-speaking race inhabiting eastern Europe. The name is in its origin identical with our "Welsh," "Welshman" and represents a Slavonic adaptation of a generic term applied by the Teutonic races at the time of the migration of peoples to all Roman provincials. It thus finds its analogies in the German name for Italy—Welschland (Wälischland), in the Walloons of the Low Countries, the "Wallgau" of Tyrol, etc. An early instance of its application to the Roman population of the Eastern empire is found in the *Traveller's Song*, where in a passage which in all probability connects itself with the early trade-route between the Baltic staple of Wollin and Byzantium, the gleeman speaks of Cæsar's realm as *Walaric*="Welshry." In verse 140 he speaks of the "Rum-walas," and it is to be observed that "Rum" is one of the words by which the Vlachs of Eastern Europe still know themselves.

The Slavs, at least in their principal extent, first knew the Roman empire through a Teutonic medium, and adopted their terms Vlach, Voloch, from the Ostro-Gothic equivalent of the Anglo-Saxon "Wealh." The name is thus of foreign origin, the native Vlachs continuing to this day to call themselves "*Rumeni*," *Romeni*, or even *Romani;* and it is from the native pronunciation of the Roman name that we have the equivalent expression *Rouman*, a word which must by no means be confined to that part of the Vlach race inhabiting the present kingdom of Roumania. This Vlach or Rouman race constitutes a distinct division of the Latin family of peoples, widely disseminated throughout eastern Europe, both north and south of the Danube. North of the Danube the Roumans inhabit, besides Walachia and Moldavia, Bessarabia and the adjoining South-Russian districts, a large part of Transylvania and the Hungarian Banat, and extend sporadically from the Bug to the Adriatic. South of the Danube the central glens of Pindus form the principal nucleus of Rouman habitation, but there is besides a considerable colony in the Epirote district of Musakja, in Ætolia and Acarnania, in various districts of Albania, Thessaly, Macedonia, and the Bulgarian principality. In Servia this element is preponderant in the Timok valley, while in Istria it is represented by the Cici, at present largely Slavonized, as are now entirely the kindred Morlachs of Dalmatia.

The centre of gravity of the Vlach or Rouman race is at present unquestionably north of the Danube, and corresponds roughly to the limits of Trajan's Dacian province. From this circumstance the popular idea has arisen that the race itself represents the descendants of the Romanized population of Trajan's Dacia, which was assumed to have maintained an unbroken existence in Walachia, Transylvania, etc., beneath the dominion of a succession of invaders. The Vlachs of Pindus, etc., on this hypothesis, were to be regarded as later immigrants from the lands north of the Danube. In 1871 Roesler published, in a collective form, a series of essays, in which he absolutely denied the claim of the Roumanian and Transylvanian Vlachs to be regarded as Dacian autochthones. He laid stress on the statements of Vopiscus and others as implying the total withdrawal of the Roman provincials from Trajan's Dacia by Aurelian, and on the non-mention by historians of a Latin population in the lands on the left bank of the lower Danube, during their successive occupation by Goths, Huns, Gepidæ, Avars, Slavs, Bulgars, and other barbarian races. He found the first trace of a Rouman settlement north of the Danube in a Transylvanian diploma of 1222. Roesler's thesis has been generally regarded as an entirely new departure in critical ethnography. As a matter of fact, his conclusions had to a great extent been already anticipated by Sultzer in his *Geschichte des Transalpinischen Daciens*, published at Vienna in 1781, and at a still earlier date by the Dalmatian historian Lucius of Traü in his work *De Regno Dalmatiæ et Croatiæ*, 1666.

The theory of the later immigration of the Roumans into their present abodes north of the Danube, as stated in its most extreme form by Roesler, commanded wide acceptance, and in Hungary it was politically utilized as a plea for refusing parity of treatment to a race of comparatively recent intruders. In Roumania itself Roesler's views were resented as an attack on Rouman nationality. Outside Roumania they found a determined opponent in Dr. Jung, of Innsbruck, who in his *Anfänge der Romänen* upheld the continuity of the Roman provincial stock in Trajan's Dacia, disputing from historic analogies the total withdrawal of the provincials by Aurelian; and the reaction against Roesler was carried still further by T. Lad. Pič (*Ueber die Abstammung der Rumänen*, 1880) and Prof. A. D. Xenopol of Jassy (*Les Roumains au Moyen Âge*, 1885).

On the whole,—as often in controversies,—it may be said that the truth lies between the two extremes. Roesler is no doubt so far right that at the time of the migration of peoples, and indeed throughout the early Middle Ages, the bulk of the Rouman people lay south of the Danube. Pič's view that the population of the Roman provinces of Mœsia, etc., were Hellenized rather than Romanized, and that it is to Trajan's Dacia alone that we must look for the Roman source of the Vlach race, conflicts with what we know of the Latinizing of the Balkan lands from inscriptions, martyrologies, Procopius's list of Justinian's Illyrian fortresses, and other sources. This Roman element south of the Danube had further received a great increase at the expense of Trajan's colonial foundation to the north when Aurelian established his New Dacia on the Mœsian side of the river. On the other hand, the analogy supplied by the withdrawal of the Roman provincials from Riparian Noricum tells against the assumption that the official withdrawal of the Roman colonists of Trajan's Dacia by Aurelian entailed the entire evacuation of the Carpathian regions by their Latin-speaking inhabitants. As on the upper Danube the continuity of the Roman population is attested by the *Vici Romanisci* of early mediæval diplomas and by other traces of a Romanic race still represented by the Ladines of Tyrol, so it is reasonable to suppose a Latin-speaking population continued to exist in the formerly thickly colonized area embracing the present Transylvania and Little Walachia, with adjoining Carpathian regions. Even as late as Justinian's time, the official connection with the old Dacian province was not wholly lost, as is shown by the erection or restoration of certain *têtes-de-pont* and *castella* on the left bank of the lower Danube.

We may therefore assume that the Latin race of eastern Europe never wholly lost touch of its former trans-Danubian strongholds. It was, however, on any showing greatly diminished there. The open country, the broad plains of what is now the Roumanian kingdom, and the Banat of Hungary were in barbarian occupation. The centre of gravity of the Roman or Romance element of Illyricum had now shifted south of the Danube. By the 6th century a large part of Thrace, Macedonia, and even of Epirus, had become Latin-speaking.

What had occurred in Trajan's Dacia in the 3d century was consummated in the 6th and 7th throughout the greater part of the South-Illyrian provinces, and the Slavonic and Avar conquests severed the official connection with eastern Rome. The overthrow of civic life and break-down of provincial organization was complete. The Roman element was uprooted from its fixed seats, and swept hither and thither by the barbarian flood. Nomadism became an essential of independent existence. On the other hand, large masses of homeless provincials were dragged off as captives in the train of their barbarian conquerors, to be distributed in servile colonies. They were thus in many cases transported by barbarian chiefs—Slav, Avar, and Bulgarian—to trans-Danubian and Pannonian regions. In the *Acts* of St. Demetrius of Thessalonica we actually find an account of such a Roman colony, which, having been carried away from South-Illyrian cities by the Avar khagan, and settled by him in the Sirmian district beyond the Save, revolted after seventy years of captivity, made their way once more across the Balkan passes, and finally settled as an independent community in the country inland from Salonica. Others, no doubt, thus transported northwards never returned. It is certain that the earliest Hungarian historians who describe the Magyar invasion of the 9th century speak of the old inhabitants of the country as Romans, and of the country they occupied as *Pascua Romanorum*; and the Russian Nestor, writing about 1100, makes the same invaders fight against Slavs and Vlachs (Volochi) in the Carpathian Mountains. So far from the first mention of the Vlachs north of the Danube occurring only in 1222, as Roesler asserts, it appears from a passage of Nicetas of Chonæ that they were to be found already in 1164 as far afield as the borders of Galicia.

It is nevertheless true that throughout the early Middle Ages the bulk of the Rouman population lay south of the Danube. It was in the Balkan lands that the Rouman race and language took their characteristic mould. It is here that this new Illyrian Romance first rises into historic prominence. Already in the 6th century, as we learn from the place names, such as Sceptecasas, Burgualtu, Clisura, etc, given by Procopius, the Rouman language was assuming, so far as its Latin elements were concerned, its typical form. In the somewhat later campaigns of Commentiolus (587) and Priscus, against the Avars and Slovenes, we find the Latin-speaking soldiery of the Eastern emperor making use of such Romance expressions as "torna, frate!" (turn, brother!), or "sculca" (out of bed) applied to a watch (*cf.* Rouman "a se culca" = Italian "coricarsi" + ex-(s-) privative). Next we find this warlike Rouman population largely incorporated in the Bulgarian kingdom, and, if we are to judge from the names Paganus and Sabinus, already supplying it with rulers in the 8th century. The blending and close contact during this period of the surviving Latin population with the Slovene settlers of the peninsula impregnated the language with its large Slavonic ingredient; and the considerable Albanian element in Rouman, as well as the still greater element of Rouman in Albanian, is alone sufficient to show that the two languages took their characteristic shapes in a contiguous area. The fact that these peculiarities are common to the Roumans north of the Danube, whose language differs dialectically from that of their southern brothers, shows that it was this southern branch that throughout the early periods of Rouman history was exercising a dominating influence. Migrations, violent transplantation, the intercourse which was kept up between the most outlying members of the race, in its very origin nomadic, at a later period actual colonization *en masse* and the political influence of the Bulgaro-Vlachian empire, no doubt contributed to propagate these southern linguistic acquisitions throughout the northern area to which the Rouman race was destined almost imperceptibly to shift its centre of gravity.

Byzantium, which had ceased to be Roman, and become Romaic, renewed its acquaintance with the descendants of the Latin provincials of Illyricum through a Slavonic medium, and applied to them the name of "Vlach," which the Slav himself had borrowed from the Goth. The first mention of Vlachs in a Byzantine source is about the year 976, when Cedrenus (ii. 439) relates the murder of the Bulgarian czar Samuel's brother "by certain Vlach wayfarers," at a spot called the Fair Oaks, between Castoria and Prespa. From this period onwards the Rouman inhabitants of the Balkan peninsula are constantly mentioned by this name, and we find a series of political organizations and territorial divisions connected with the name of "Vlachia." Within the limits of the present article it is impossible to give more than a short synopsis of the most important of these, while for a history of the later Rouman principalities of Walachia and Moldavia the reader is referred to the article ROUMANIA.

1. *The Bulgaro-Vlach Empire.*—After the overthrow of the older Bulgarian czardom by Basil Bulgaroktonos, the Vlach population of Thrace, Hæmus, and the Mœsian lands passed once more under Byzantine dominion; and in 1185 a heavy tax, levied in kind on the cattle of these warlike mountain shepherds, stirred the Vlachs to revolt against the emperor Isaac Angelus, and under the leadership of two brothers, Peter and Asen, to found a new Bulgaro-Vlachian empire, which ended with Kaliman II. in 1257. The dominions of these half-Slavonic half-Rouman emperors extended north of the Danube over a great deal of what is now Roumania, and it was during this period that the Vlach population north of the river seems to have been most largely reinforced. The French traveller Rubruquis speaks of all the country between Don and Danube as "Asen's land" or "Blakia."

2. *Great Walachia* (Μεγάλη Βλαχία).—It is from Anna Comnena, in the second half of the 11th century, that we first hear of a Vlach settlement, the nucleus of which was the mountainous region of Thessaly. Benjamin of Tudela, in the succeeding century, gives an interesting account of this Great Walachia, which was then completely independent. It embraced the southern and central ranges of Pindus, and extended over part of Macedonia, thus including the region in which the Roman settlers mentioned in the *Acts* of St. Demetrius had fixed their abode. After the Latin conquest of Constantinople Great Walachia was included in the enlarged despotate of Epirus, but it soon reappears as an independent principality under its old name, which, after passing under the yoke of the Serb emperor Dushan, was finally conquered by the Turks in 1393. Many of their old privileges were still accorded to the inhabitants, and their taxes were limited to an annual tribute to the sultana Valide. Since this period the Megalovlachites have been largely Hellenized, but they are still represented by the flourishing Tzintzar settlements of Pindus, and traces are at present perceptible among them of a national Rouman reaction.

3. *Little Walachia* (Μικρά Βλαχία) was a name applied by Byzantine writers to the Rouman settlements of Ætolia and Acarnania, and with it may be included "Upper Walachia" or Ανώβλαχα. Its inhabitants are still represented by the Tzintzars of the Aspropotamo and the Karaguni (Black Capes) of Acarnania.

4. *The Morlachs* (*Mavrovlachi*) *of the West.*—These are already mentioned as *Nigri Latini* by the Presbyter of Dioclea (*circ.* 1150) in the old Dalmatian littoral and the mountains of what is now Montenegro, Herzegovina, and North Albania. Other colonies extended through a great part of the old Servian interior, where is a region still called Stara Vlaška or "Old Walachia." The great commercial staple of the east Adriatic shores, the republic of Ragusa, seems in its origin to have been a Rouman settlement, and many Vlach traces survived in its later dialect. Philippus de Diversis, who described the city as it existed in 1440, says that "the various officers of the republic do not make use either of Slav or Italian, with which they converse with strangers, but a certain other dialect only partially intelligible to us Latins," and cites words with strong Rouman affinities. In the mountains above Ragusa a number of Vlach tribes are mentioned in the archives of that city, and the original relationship of the Ragusans and the nomadic Alpine representatives of the Roman provincials, who preserved a traditional knowledge of the old lines of communication throughout the peninsula, explains the extraordinary development of the Ragusan commerce. In the 14th century the Mavrovlachi or Morlachs extended themselves towards the Croatian borders, and a large part of maritime Croatia and northern Dalmatia began to be known as "Morlacchia." A "Major Vlachia" was formed about the triple frontier of Bosnia, Croatia, and Dalmatia, and a "Little Walachia" as far north as Posega. The Morlachs have now become Slavonized.

5. *Cici of Istria.*—The extreme Rouman offshoot to the northwest is still represented by the Cici of the Val d'Arsa and adjoining Istrian districts. They represent a 15th-century Morlach colony from the Isle of Veglia, and had formerly a wider extension to Trieste and the counties of Gradisca and Gorizia. The Cici are at present rapidly losing their native tongue, which is the last remaining representative of the old Morlach, and forms a connecting link between the Daco-Roman (or Roumanian) and the Macedo-Roman (or Tzintzar) dialects.

6. *Roumans of Transylvania and Hungary.*—As already stated, a large part of the Hungarian plains were, at the coming of the Magyars in the 9th century, known as *Pascua Romanorum.* At a later period privileged Rouman communities existed at Fogaras, where was a *Silva Vlachorum*, at Marmaros, Deva, Hatzeg, Hunyad, and Lugos, and in the Banat were seven Rouman districts. Two of the greatest figures in Hungarian history—John Corvinus of Hunyad, and his son King Matthias—were due to this element. Oppressed by the dominant race, which had deprived them of their ancient privileges, the Roumans of Transylvania and the Banat rose in 1785, under Horia, Closca, and Crischanu. This Rouman "Jacquerie" was suppressed but Joseph II. declared the peasants free. Since that date the Rouman element in this part of the old Dacian region has largely increased in numbers, though it has hitherto failed to secure its political rights. The contiguous district of the Bukovina, a part of Moldavia annexed to the Hapsburg dominions in 1775, remains under the Austrian Government.

The present numerical strength of the Roumanians may approximately be given as follows:

Southern or Tzintzar branch in Pindus, etc.	225,000
Roumans of Tirnok district	150,000
Roumanians	4,500,000
In Austria-Hungary	3,500,000
In Bessarabia and South Russia	600,000
Total	8,975,000

In features the Vlachs especially of the Carpathian valleys present decidedly Roman characteristics, and it is not unfrequent to find types which occur in North Italy and amongst Spaniards and Provençals. They are usually short and dark. Those of Pindus have sharper-cut features and some Slovene traits in their physiognomy. The race has a great natural capacity for trade and manufacture. The Vlachs excel as builders and artisans, but notably as workers in metal; their financial enterprise is also remarkable, and some of the principal banking establishments in Vienna are due to members of this race. An extraordinary example of their successful enterprise in the Balkan peninsula is supplied by the history of Moschopolis on the Epirote side of Pindus, which was founded by a Vlach colony in the 16th century, and which not only became a populous commercial staple but a centre of literary culture. Moschopolis possessed a large public library, flourishing schools, and a printing press, from which issued both Greek and Rouman books of a religious and scholastic nature. Joannina, since completely Hellenized, was also of Rouman origin. Metzovo (Minciu) is another flourishing Rouman colony in the same region, and, though Moschopolis has fallen a victim to the ravages of the wild Arnauts, a local successor has sprung up in the rising town of Gjurtza. The Roumans make good soldiers, as was seen at Plevna. In their customs and folklore both Latin and Slavonic traditions assert themselves as in their language. Of their Roman traditions the Trajan saga, the celebration of the Rosalia and Kalendæ, the belief in the "striga" (witch), the names of the months and days of the week, may be taken as typical examples. Some Roman words connected with the Christian religion, like biserica (basilica) = a church, botez = baptizo, duminica = Sunday, preot (presbyter) = priest, point to a continuous tradition of the Illyrian church, though most of their ecclesiastical terms, like their liturgy and alphabet, were derived from the old Slovene. In most that concerns political organization the Slavonic element is also preponderant, though there are words like impărat = imperator, and domn = dominus, which point to the old stock. Many words relating to kinship are also Latin, some like vitrig (vitricus) = father-in-law being alone preserved by this branch of the Romance family. Although of the actual vocabulary only about one-fifth is Latin, and two-fifths, or about double the amount, Slavonic (see Cihac, *Dictionnaire d'Étymologie Daco-Romaine*), the greater proportion of the words in common use is still Latin. Many words, however, of common and indispensable use, those even connected with ideas nearest to the heart, as for instance the Rouman iubesc = to love, and máică = a mother, are themselves of Slavonic origin. Alike in the dwellings, customs, and costumes of the Vlach race we encounter at every turn the dominating influence of the Slav peoples by whom they were surrounded. This external influence, however, has not by any means affected the strong pride of Roman origin which is the heirloom of all members of the Rouman race. Hellenization itself, hitherto successful among the southern Roumans, has received a check in the Pindus region, while north of the Danube the Rouman race is continually gaining at the expense of its neighbors. A glance at the ethnographic map of eastern Europe shows that the reconquest of Trajan's Dacia by the Latin race is already practically completed, and with the triumphant progress of the principle of nationality in the Danubian lands the reunion of *Dacia Romana* under a single sceptre cannot long be deferred. (A. J. E.)

VŁADIKAVKAZ, a fortified town of Russia, in the province of Terek, is advantageously and picturesquely situated at the northern base of the Great Caucasus chain, on a raised plain, 2230 feet above the sea-level, where the gorge of the Terek emerges from the mountain tracts. It is the present terminus of the railway from ROSTOFF (*q.v.*), which is intended ultimately to cross the main ridge. The fortress, formerly but a small redoubt, erected in 1784 at the northern entrance of the pass by which the Caucasus used to be crossed, now stands higher up, and is connected by a bridge with the town proper. Vładikavkaz is now the capital of the province. It is tidily built, and its population since it became an entrepôt for trade between Russia and Caucasus has rapidly grown (32,340 in 1883). The transport of merchandise is the principal occupation of the place, 400,000 cwts. of goods annually arriving by rail to be forwarded to Tiflis, while 160,000 cwts. are sent from Vładikavkaz northwards.

VLADIMIR, a government of middle Russia, bounded by Moscow and Tver on the W., Yarosłav and Kostroma on the N., Nijniy Novgorod on the E., Tamboff and Ryazañ on the S., has an area of 18,864 square miles. It extends over the eastern parts of the central plateau of middle Russia, which has an average elevation of from 800 to 950 feet above the sea, and is grooved by river valleys to a depth ranging from 300 to 450 feet below the general level, so that the country has a hilly appearance on the banks of the chief rivers. The lacustrine depression of the middle Volga and Oka extends into the eastern parts of the government. The Upper Carboniferous limestones, of which it is mostly built up, are covered with Permian sandstones towards the east, and patches of Jurassic clays—denuded remnants of formerly extensive deposits—are scattered over its surface. Cretaceous deposits are supposed to make their appearance in the south. The whole is covered with a thick sheet of boulder clay, considered as the bottom-moraine of the North-European ice-sheet, and overlaid, in its turn, in the depressions, by extensive Lacustrine clays and sands. The soil is thus for the most part unfertile, save in the district of Yurieff, where are found patches of black earth, which of late have occasioned a good deal of discussion among Russian geologists. Iron-ore is widely diffused, and china clay and gypsum are met with in several places. Peat is of common occurrence. As for coal, it is certain that the coal-bearing Lower Carboniferous strata of the Moscow basin would be encountered by boring to a certain depth; no such explorations, however, have yet been made, as forests still cover extensive tracts in the southeast, and the numerous manufactures of Vladimir suffer from no lack of fuel. The climate resembles that of Moscow, but is a little colder, and still more continental; the average yearly temperature at Vladimir is 38° F. (January, 16°; July, 66.5°).

The Oka flows through the government for 85 miles, and is navigable throughout. Of its tributaries, the Klyasma is navigable to Kovroff, and even to Vladimir in summer; and timber is floated on the Teza. Small lakes are numerous; that of Plescheyevo or Pereyasłavl (5 miles in length) has historical associations, Peter I. having here acquired in his boyhood his first experiences in navigation. Marshes cover more than half a million acres.

The population (1,359,330 in 1883) is thoroughly Great Russian; the Finnish tribes, Muroma and Merya, which formerly inhabited the region, have been absorbed by the Slavonians, as also have the Karelians who are supposed to have formerly inhabited the territory; the descendants of the few hundred Karelian families, which were settled by Peter I. on the shores of Lake Pereyasłavl, still, however, maintain their language. Agriculture is carried on everywhere, but is in a prosperous state only on the left bank of the Klyasma, and corn is imported. The culture of flax, both for local manufactures and for export—especially about Melenki—is important; so also are that of hemp and gardening. Natural pastures being by no means deficient, the number of cattle is greater than might be expected in a province so backward in agriculture. The average crops of the years 1883–85, were—rye, 1,400,300 quarters; oats, 1,097,000; wheat, 36,400; barley, 63,000; other grains, 250,800; and potatoes, 52,300. In 1883 there were 323,000 cattle, 210,050 horses, and 330,050 sheep.

A distinctive feature of Vladimir is the great variety of petty trades carried on in its villages by peasants who still continue to cultivate their allotments and thus combine manufacture with agriculture. Nearly every village has its own specialty, and, while in some of them almost all the male population leave their homes and go in numerous *artels* (see vol. xxi. p. 92) all over Russia as carpenters, masons, iron-roof makers, or as *ofeni* (peddlers or travelling merchants), other villages have their specialties in some branch of manufactured produce. Nearly 30,000 carpenters leave Vladimir every year. Whole villages are engaged in painting sacred pictures or ikons, and there are weekly fairs, where no fewer than 130 cart-loads of planks for such works are bought every week during winter. Although the ikons are sold at a shilling [24 cents] the hundred, the aggregate trade is valued at £150,000 [$729,000] a year; and the Vladimir (or rather Suzdal) pictures spread all over Russia and the Balkan peninsula. In other villages some 1200 men are employed in making sickles, knives, or locks. Wooden vessels, boxes, and baskets, *lapti* (shoes made of lime-tree bark which are worn in Great Russia, and are produced by the million), wheels and sledges, sieves, combs, woollen stockings and gloves, sheepskins and sheepskin gloves for peasants, felt, all kinds of toys, earthenware, and finally all kinds of woven fabrics, are so many specialties of separate villages. In 1884, 102,500 persons were directly engaged in petty trades, in which indeed Vladimir occupies the first rank in Russia, the annual production (63,000,000 roubles) [$48,510,000], being one-third of the total for the whole country, Moscow coming next with 37,300,000 roubles [$28,721,000].

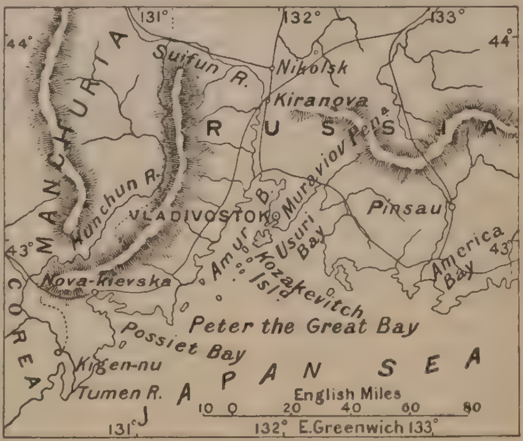
The manufactures of Vladimir are equally important: out of the aggregate production of the fifty governments of European Russia (1,329,602,000 roubles [$1,023,793,540] in 1884), Vladimir was returned for 88,827,000 roubles, [$68,396,790] exclusive of numerous minor manufactures not included in the census. In the number of workmen employed in manufacture (102,900) Vladimir is second only to Moscow and in its production it is second only to Moscow and St. Petersburg. The chief industrial establishments are cotton and linen factories, glass, chemical, and iron works, distilleries, and tanneries.

Vladimir is divided into fourteen districts, the chief towns of which (with populations in 1884) are VLADIMIR (*q.v.*), 18,420; Alexandroff, 6915; Ivanovo-Voznesensk, 14,060; Kovroff, 8050; Melenki, 6470; MUROM (*q.v.*), 13,680; Pereyasłavl Zalyesskiy, 7470; Pokroff, 2700; SHUYA (*q.v.*), 21,430; Sudogda, 1880; Suzdal, 6770; Vyazniki, 6015; and Yurieff Polskiy, 5400. Kirzhatch (3285), Voznesensk (6000), and Gavriłovsk (1780) have also municipal institutions. Ivanovo, Gusevsk, Khołui, and several others, though mere villages, are more important than some district towns.

VLADIMIR, capital of the above government, is known in history as Vladimir-on-the-Klyasma, to distinguish it from Vladimir in Volhynia. It is picturesquely situated on the Klyasma and Lybed, 114 miles by rail to the east of Moscow. The Lybed divides it into two parts. Extensive cherry gardens occupy the surrounding slopes, each with its small watch-tower, having cords drawn in all directions to be shaken by the watcher when birds alight. The kreml stands on a hill and contains two very old cathedrals—the Uspenskiy (1150), where all princes of Vladimir have been buried, and the Dmitrievskiy, restored in 1834 in its old style. Several churches date from the 12th century. The "Golden Gate"—a triumphal gate surmounted by a church—was built by Andrei Bogolubskiy in 1158. On the whole Vladimir is a decaying place; its population has only risen to 18,420 in 1884 from 13,865 in 1859. The manufactures are for the most part insignificant, and trade has not the importance it has in some of the district towns.

Vladimir was founded in the 12th century. It first comes into notice in 1151, when Andrei Bogolubskiy secretly left Vyshgorod—the domain of his father in the principality of Kieff—and migrated to the newly settled land of Suzdal, where he became (1157) grand-prince of the principalities of Vladimir, Suzdal, and Rostoff. During the next century Vladimir became the chief town of the Russian settlements in the basin of the Oka, and till 1328 it disputed the superiority with the new principality of Moscow (*q.v.*). In the 14th century it began to fall to decay; and, like Pskoff, it is now one of the less important provincial cities of Russia.

VŁADIVOSTOK, the chief naval station of Russia on the Pacific, is situated in 43° 7′ N. lat. and 131° 55′ E. long., on the Gulf of Peter the Great in the sea of Japan. This gulf, which has a length of nearly 50 miles, and a width at its entrance of 112 miles, is divided into two large bays—Amur and Usuri—by the hilly peninsula of Muravioff-Amurskiy, continued in a group of islands, of which the Kozakevitch or Russkiy (Johanga-tun) is the largest. A narrow strait, which has received the high-sounding name of the Eastern Bosphorus, separates this from the peninsula, and Vładivostok occupies the northern shore of one of its horn-like expansions, which the Russians have called the Golden Horn (*Zolotoi Rog*). The depth of the Eastern Bosphorus ranges from 13 to 20 fathoms, and that of the Golden Horn from 5 to 13, the latter thus affording a spacious harbor,—one of the finest, indeed, in the world. The hills are covered with forests of oak, lime, birch, maple, cork, walnut, acacia, ash, aspen, poplar, elm, apple, pear, and wild cherry, with a rich undergrowth of the most varied shrubs. Excellent timber is supplied by oak and cedar forests not far off. The climate, however, is severe, if compared with that of corresponding latitudes in Europe. Though standing in almost the same parallel as Marseilles, Vładivostok has an average annual temperature of only 38·5° F., and, although the gulf itself never freezes, a thin ice-crust forms along the shores in December, keeping ships ice-bound for from thirty to forty-five days.



Environs of Vładivostok.

The settlement of Vładivostok, though founded only in 1861, had in 1886 12,500 inhabitants, chiefly military; and for hundreds of miles inland the sole population consists of the small military posts by which communication is maintained up the Suifun to Lake Khangka and the Cossack settlements on the Usuri. Vładivostok is connected with headquarters by telegraph.

Since the transference of the navy workshops from Nikolaievsk the place has gained in importance. It has a pro-gymnasium for boys (60 pupils), a club and a newspaper. The imports of both Russian and foreign goods during the last five years have reached an average of from 2½ [$1,925,000] to 3 millions of roubles [$2,310,000]; but the exports are insignificant. Some 3000 or 4000 Coreans find employment in the Gulf of Peter the Great in gathering the edible seaweed *Laminaria saccharina*, of which about 70,000 cwts. (£45,000) [$218,700]) are sent to China annually. The discovery of gold in the neighboring alluvial deposits brought together some hundreds of Chinese, but the Russian Government compelled them to withdraw. The amount of gold is, however, not believed to be remunerative.

The Gulf of Peter the Great was discovered in 1852 by the French corvette "Capricieuse," and named the Golfe d'Anville. Two years later Count Putyatin, on board the frigate "Pallada," described the southwestern part of the gulf and the Bay of Possiet. In 1855 an English squadron mapped its middle portion as far as Lefu (Askold) Island, and gave it the name of Victoria Bay. The whole gulf was mapped in 1859 by the Russian ships "America" and "Stryelok," and two years later a Russian post, which afterwards received the name of Vladivostok, was established.

VOGELWEIDE See WALTER VON DER VOGELWEIDE.

VOGHERA (*Vicus Iriæ*), a town of Italy, in the province of Pavia, and 19 miles by rail to the south-southwest of that city, on the Staffora, formerly the Iria (a tributary of the Po), here crossed by a fine bridge. The fortifications erected by the Visconti in the Middle Ages have given place to a series of shady promenades. The large church of San Lorenzo dates its foundation from the 11th century, but was remodelled in the baroco style about the beginning of the 17th. The neighborhood is fertile and produces much silk, in which, as well as in corn and wine, an active trade is carried on. The population in 1881 was 10,785.

VOGLER, GEORGE JOSEPH (1749–1814), usually known as Abbé Vogler, organist and composer, was born at Würzburg, June 15, 1749. His father, a violin maker, while educating him for the church, took every opportunity of encouraging his musical talent, which was so marked that at ten years old he could not only play the organ well, but had also acquired a fair command of the violin and some other instruments without instruction. In 1769 he prosecuted his higher studies at Bamberg, removing thence in 1771 to Mannheim. Here he composed a ballet for the elector Karl Theodor, who charmed with his talent, sent him to Bologna, to study under the Padre Martini. Unsatisfied with the method of that learned theorist, he studied for five months under Valotti, at Padua, and afterwards proceeded to Rome, where he was ordained priest in 1773, admitted to the famous academy of Arcadia, made a knight of the Golden Spur, and appointed protonotary and chamberlain to the pope.

On his return to Mannheim in 1775 Vogler was appointed court chaplain and second "maestro di cappella." He now established his first great music school, to which Winter, Ritter, Kraus, Danzi, and Knecht came for instruction. His pupils were devoted to him, but he made innumerable enemies, for the principles upon which he taught were confessedly opposed to those of all other teachers whatsoever. He had invented a new system of fingering for the harpsichord, a new form of construction for the organ, and a new system of musical theory founded upon that of Valotti. Mozart condemned the fingering as "miserable." The proposed change in the construction of the organ consisted in simplifying the mechanism, introducing free-reeds in place of ordinary reed-stops, and substituting unisonous stops for the great "mixtures" then in vogue.[1] The theoretical system, though professedly based upon Valotti's principles, was to a great extent empirical, and, like the scheme for revolutionizing the organ, has long been forgotten. Nevertheless, a certain substratum of truth seems to have underlain all his new heresies; and, by virtue of this, in spite of a rage for reform amounting almost to madness, Vogler undoubtedly exercised a powerful influence over the progress of musical science, and numbered among his disciples some of the greatest geniuses of the period.

In 1778 the elector removed his court to Munich. Vogler followed him thither in 1780, but, dissatisfied with the reception accorded to his dramatic compositions, soon quitted his post, and travelled for some years in Spain, Greece, Armenia, remote districts of Asia and Africa, and even Greenland, in search of uncorrupted forms of national melody. In 1786 he was appointed "kapellmeister" to the king of Sweden, founded his second music school at Stockholm, and attained extraordinary celebrity by his performances on an instrument called the "orchestrion,"—a species of organ invented by himself. In 1790 he brought this instrument to London, and performed upon it with great effect at the Pantheon, for the concert-room of which he also constructed an organ upon his own principles. Gerber alleges that organ pedals were unknown in England until Vogler introduced them, during his residence in London. This assertion is disapproved by a MS. Concerto, by Handel, now in the Royal Library at Buckingham Palace, dated February 17, 1740, and containing an *obbligato* pedal part; nevertheless, it is certain that the abbé's pedal-playing excited great attention. His most popular pieces were a fugue on themes from the "Hallelujah Chorus," composed after a visit to the Handel festival at Westminster Abbey, and *A Musical Picture for the Organ*, by Knecht, containing the imitation of a storm.

From London Vogler proceeded to Rotterdam and the chief towns on the Rhine. At Esslingen he was presented with the "wine of honor" reserved for the use of sovereigns. At Frankfort he attended the coronation of the emperor Leopold II. He then visited Stockholm, and after a long residence there, interrupted by endless wanderings, once more established himself in Germany, where his compositions, both sacred and dramatic, received at last the full credit that was due to them. To trace his journeys from end to end of Europe would be impossible. We hear of him at Berlin in 1800, at Vienna in 1804, and at Munich in 1806. But while at Frankfort in 1807 he received an invitation from Louis I., grand-duke of Hesse-Darmstadt, offering him the appointment of "kapellmeister," with the order of merit, the title of privy councillor, a salary of 3000 florins [$1500], a house, a table supplied from the duke's own kitchen, and other privileges, which determined him to bring his wanderings at last to a close.

At Darmstadt he opened his third and most famous music school, the chief ornaments of which were Gänsbacher, Weber and Meyerbeer. Gänsbacher had been his pupil at Vienna. Weber had studied under him in 1803, and once more sought his old master's help in 1810, though rather in the way of advice than instruction. Meyerbeer had been first introduced to him by means of a fugue which he criticised very severely, though he saw in it so much talent that he invited the composer to become his pupil. The three young students were inseparable, and their affection for their old master was unbounded. One of Vogler's latest exploits was a journey to Frankfort in 1810, to witness the production of Weber's *Sylvana*. He continued hard at work, genial and pleasant to the last, and died suddenly of apoplexy at Darmstadt, May 6, 1814.

Opinions are strangely divided as to the reality of Vogler's vocation. Some have pronounced him a genius, others a charlatan. Mozart was strongly prejudiced against him. That he was a brilliant and accomplished performer no one denies. It is certain that he was an excellent, if an eccentric, teacher. But his theories were visionary, and of his numberless compositions not one has survived to the present day.

---

[1] An organ built on the "unisonous system" stood for many years in Wornum's Music Hall, Store Street, London.

VOICE is produced by the vibrations of the vocal cords, two ligaments or bands of fibrous elastic tissue situated in the larynx. It is to be distinguished from *speech*, which is the production of sounds intended to express ideas. Many of the lower animals have voice, but none have the power of speech in the sense in which man possesses that faculty. There may be speech without voice, as in whispering, whilst in singing a scale of musical tones we have voice without speech. Regarding speech, see PHONETICS and SPEECH-SOUNDS; also the articles on the various letters of the alphabet.

1. *Physiological Anatomy.*—The organ of voice, the *larynx*, is situated in man in the upper and fore part of the neck, where it forms a well-known prominence in the middle line. It opens below into the trachea or windpipe, and above into the cavity of the pharynx, and it consists of a framework of cartilages, connected by elastic membranes or ligaments, two of which constitute the true vocal cords. These cartilages are movable on each other by the action of various muscles, which thus regulate the position and the tension of the vocal cords. The trachea conveys the blast of air from the lungs during expiration, and the whole apparatus may be compared to an acoustical contrivance in which the lungs represent the wind chest and the trachea the tube passing from the wind chest to the sounding body contained in the larynx. Suppose two tight bands of any elastic membrane, such as thin sheet india-rubber, stretched over the end of a wide glass tube so as to leave a narrow chink between the free borders of the membrane, and that a powerful blast of air is driven through the tube by a bellows. The pressure would so distend the margins of the membrane as to open the aperture and allow the air to escape; this would cause a fall of pressure, and the edges of the membrane would spring back by their elasticity to their former position; again the pressure would increase, and again the edges of the membrane would be distended; and those actions would be so quickly repeated as to cause the edges of the membrane to vibrate with sufficient rapidity to produce a musical tone, the pitch of which would depend on the number of vibrations executed in a second of time. The condensation and rarefaction of the air thus produced are the chief cause of the tone, as Von Helmholtz has pointed out, and in this way the larynx resembles the syren in its mode of producing tone (see ACOUSTICS). It is evident also that the intensity or loudness of the tone would be determined by the amplitude of the vibrations of the margins of the membrane, and that its pitch would be affected by any arrangements effecting an increase or decrease of the tension of the margins of the membrane. The pitch might also be raised by the strength of the current of air, because the great amplitude of the vibrations would increase the mean tension of the elastic membrane. With tones of medium pitch, the pressure of the air in the trachea is equal to that of a column of mercury of 160 mm.; with high pitch, 920 mm.; and with notes of very high pitch, 945 mm.; whilst in whispering it may fall as low as that represented by 30 mm. of water. Such is a general conception of the mechanism of voice.

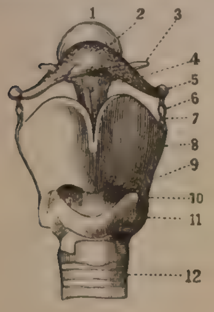


FIG 1.

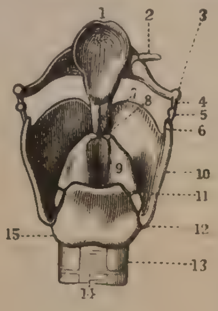

FIG 2.

FIG. 1.—Cartilages and ligaments of the larynx seen from the front; half natural size. 1, epiglottis; 2. hyoid bone; 3, small cornu of hyoid bone; 4, middle thyro-hyoid ligament; 5, great cornu of hyoid bone; 6, small nodules of cartilage (*cartilago triticea*); 7, the lateral thyro-hyoid ligament; 8, left lamina or wing of thyroid cartilage; 9, cricoid cartilage; 10, lower cornu of thyroid cartilage; 11, part of cricoid united to the thyroid by the middle crico-thyroid ligament; 12, second ring of trachea. (From Krause.)

FIG. 2.—Cartilages and ligament of larynx seen from behind; half natural size. 1, epiglottis; 2, lesser cornu of hyoid bone; 3, greater cornu of hyoid; 4, lateral thyro-hyoid ligament; 5, cartilago triticea; 6, upper cornu of thyroid; 7, thyro-epiglottic ligament; 8, cartilages of Santorini; 9, arytenoid cartilages; 10, left lamina of thyroid; 11, muscular process of arytenoid cartilage; 12, inferior cornu of thyroid; 13, first ring of trachea; 14, posterior membranous wall of trachea; 15, lamina of cricoid cartilage. (From Krause.)

The *cartilages* form the framework of the larynx. They consist of three single pieces (the thyroid, the cricoid, and the cartilage of the epiglottis) and of three pairs (two arytenoids, two cornicula laryngis or cartilages of Santorini, and two cuneiform cartilages or cartilages of Wrisberg), see Figs. 1 and 2. The epiglottis, the cornicula laryngis, the cuneiform cartilages, and the apices of the arytenoids are composed of yellow or elastic fibro-cartilage, while the cartilage of all the others is of the hyaline variety, resembling that of the costal or rib cartilages. These cartilages are bound together by ligaments, some of which are seen in Figs. 1 and 2, whilst the remainder are represented in Fig. 3. The ligaments specially concerned in the production of voice are the *inferior thyro-arytenoid ligaments*, or true vocal cords. These are composed of fine elastic fibres attached behind to the anterior projection of the base of the arytenoid cartilages, *processus vocalis*, 3 in Fig. 3, and in front to the middle of the angle between the wings or laminæ of the thyroid cartilage. They are practically continuous with the lateral crico-thyroid ligaments, 6 in Fig. 3.

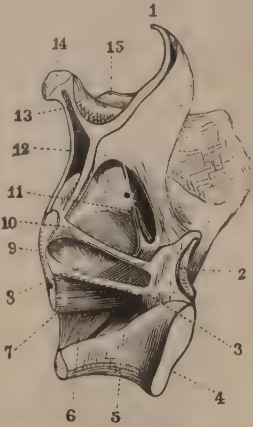

FIG. 3.—Right half of the larynx, from a vertical and slightly oblique section; two-thirds natural size. 1, epiglottis; 2, arytenoid cartilage; 3, processus vocalis of arytenoid; 4, cricoid cartilage; 5, capsular thyro-hyoid ligament; 6, lateral crico-thyroid ligament; 7, postertor crico-thyroid ligament; 8, inferior thyro-arytenoid ligament, or true vocal cord; 9, thyroid cartilage; 10, superior thyro-arytenoid ligament, or false vocal cord; 11, thyro-ary-epiglottideus muscle; 12, middle thyro-hyoid ligament; 13, hyo-epiglottic ligament; 14, body of hyoid bone; 15, smaller cornu of hyoid bone. (From Krause.)

The *cavity* of the larynx is divided into an upper and lower portion by the narrow aperture of the *glottis* or chink between the edges of the true vocal cords, the *rima glottidis*. Immediately above the true vocal cords, between these and the false vocal cords, there is on each side a recess or pouch termed the *ventricle* of Morgagni, and opening from each ventricle there is a still smaller recess, the *laryngeal pouch*, which passes for the space of half an inch between the superior vocal cords inside and the thyroid cartilage outside, reaching as high as the upper border of that cartilage at the side of the epiglottis. The ventricles no doubt permit a free vibration of the true vocal cords (Quain). The upper aperture of the glottis is triangular, wide in front and narrow behind; and, when seen from above by means of the laryngoscope, it presents the view represented in Fig. 4. The aperture is bounded in front by the epiglottis *e*, behind by the summits of the arytenoid cartilages *ar*, and on the sides by two folds of mucous membrane, the aryteno-epiglottic folds, *ae*. The rounded elevations corresponding to the cornicula laryngis and cuneiform cartilages, *c*, and also the cushion of the epiglottis, *e*, are readily seen in the laryngoscopic picture. The glottis, *o*, is seen in the form of a long narrow fissure, bounded by the true vocal cords, *ti*, whilst above them we have the false vocal cords, *ts*, and between the true and false cords the opening of the ventricle, *v*. The *rima glottidis*, between the true vocal cords, in the adult male measures about 23 millimetres, or nearly an inch, from before backwards, and from 6 to 12 millimetres across its widest part, according to the degree of dilatation. In females and in males before puberty the antero-posterior diameter is about

17 millimetres, and its transverse diameter about 4 millimetres. The vocal cords of the adult male are in length about 15 millimetres, and of the adult female about 11 millimetres. The larynx is lined with a layer of epithelium, which is closely adherent to underlying structures, more especially over the true vocal cords. The cells of the epithelium, in the greater portion of the larynx, are of the columnar ciliated variety, and by the vibratory action of the cilia mucus is driven upwards, but over the true vocal cords the epithelium is squamous. Patches of squamous epithelium are also found in the ciliated tract above the glottis, on the under surface of the epiglottis, on the inner surface of the arytenoid cartilages, and on the free border of the upper or false cords. Numerous mucous glands exist in the lining membrane of the larynx, more especially in the epiglottis. In each laryngeal pouch there are sixty to seventy such glands, surrounded by fat.

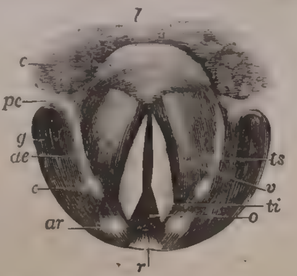

FIG. 4. — Laryngoscopic view of the glottis. *l*, tongue; *e*, epiglottis; *pe*, pharyngo-epiglottic fold; *g*, pharyngo-laryngeal groove; *ae*, aryteno-epiglottic fold; *c*, cuneiform cartilage, or cartilage of Wrisberg; *ar*, arytenoid cartilage; *r*, inter-arytenoid fold; *o*, glottis; *v*, ventricle; *ti*, inferior or true vocal cord; *ts*, superior or false vocal cord. (From Mandl.)

We are now in a position to understand the action of the *muscles* of the larynx by which the vocal cords, forming the *rima glottidis*, can be tightened or relaxed, and by which they can be approximated or separated. Besides certain extrinsic muscles—sterno-hyoid, omo-hyoid, sterno-thyroid, and thyro-hyoid—which move the larynx as a whole, there are *intrinsic* muscles which move the cartilages on each other. Some of these are seen in Fig. 5. These muscles are (*a*) the crico-thyroid, (*b*) the posterior crico-arytenoid, (*c*) the lateral crico-arytenoid, (*d*) the thyro-arytenoid, (*e*) the arytenoid, and (*f*) the aryteno-epiglottidean. Their action will be readily understood with the aid of the diagrams in Fig. 6. (1) The *crico-thyroid* is a short-thick triangular muscle, its fibres passing from the cricoid cartilage obliquely upwards and outwards to be inserted into the lower border of the thyroid cartilage and to the outer border of its lower horn. When the muscle contracts, the cricoid and thyroid cartilages are approximated. In this action, however, it is not the thyroid that is depressed on the cricoid, as is generally stated, but the thyroid being fixed in position by the action of the extrinsic muscles, the anterior border of the cricoid is drawn upwards, whilst its posterior border, in consequence of a revolution around the axis uniting the articulations between the lower cornua of the cricoid and the thyroid, is depressed, carrying the arytenoid cartilages along with it. Thus the vocal cords are stretched. (2) The *thyro-arytenoid* has been divided by anatomists into two parts—one, the internal, lying close to the true vocal cord, and the other, external, immediately within the ala of the thyroid cartilage. Many of the fibres of the anterior portion pass from the thyroid cartilage with a slight curve (concavity inwards) to the processus vocalis at the base of the arytenoid cartilage. They are thus parallel with the true vocal cord, and when they contract the arytenoids are drawn forwards, carrying with them the posterior part of the cricoid and relaxing the vocal cords. Thus the thyro-arytenoids are the antagonists of the crico-thyroids. Ludwig has pointed out that certain fibres (*portio-ary-vocalis*) arise from the side of the cord itself and pass obliquely back to the processus vocalis. These will tighten the parts of the cord in front and relax the parts behind their points of attachment. Some of the fibres of the outer portion run obliquely upwards from the side of the crico-thyroid membrane, pass through the antero-posterior fibres of the inner portion of the muscle, and finally end in the tissue of the false cord. These fibres have been supposed to render the edge of the cord more prominent. Other fibres inserted into the processus vocalis will rotate slightly the arytenoid outwards, whilst a few passing up into the aryteno-epiglottidean folds may assist in depressing the epiglottis (Quain). (3) The *posterior* and *lateral crico-arytenoid* muscles have antagonistic actions, and may be considered together. The *posterior* arise from the posterior surface of the cricoid cartilage, and passing upwards and outwards are attached to the outer angle of the base of the arytenoid. On the other hand, the *lateral* arise from the upper border of the cricoid as far back as the articular surface for the arytenoid, pass backwards and upwards, and are also inserted into the outer angle of the base of the arytenoid before the attachment of the posterior crico-arytenoid. Imagine the pyramidal form of the arytenoid cartilages. To the inner angle of the triangular base are attached, as already described, the true vocal cords; and to the outer angle the two muscles in question. The posterior crico-arytenoids draw the outer angles backwards and inwards, thus rotating the inner angles, or processus vocalis, outwards, and, when the two muscles act, widening the rima glottidis. This action is opposed by the lateral crico-thyroids, which draw the outer angle forwards and outwards, rotate the inner angles inwards, and thus approximate the cords. (4) The *arytenoids* pass from the one arytenoid cartilage to the other, and in action these cartilages will be approximated and slightly depressed. (5) The *aryteno-epiglottidean* muscles arise near the outer angles of the arytenoid; their fibres pass obliquely upwards, decussate, and are inserted partly into the outer and upper border of the opposite cartilage, partly into the aryteno-epiglottic fold, and partly join the fibres of the thyro-arytenoids. In action they assist in bringing the arytenoids together, whilst they also draw down the epiglottis, and constrict the upper aperture of the larynx. The vocal cords will be also relaxed by the elasticity of the parts.

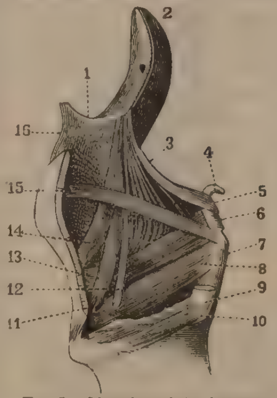

FIG. 5.—Muscles of the left side of the larynx, seen from within; two-thirds natural size. 1, hyo-epiglottic ligament, seen in profile; 2, epiglottis; 3, aryteno-epiglottic muscle; 4, Santorini's cartilage; 5, oblique arytenoid muscle; 6, transverse arytenoid muscle, seen in profile; 7, posterior crico-arytenoid; 8, lateral crico-arytenoid; 9, lower cornu of thyroid cartilage cut through; 10, insertion of posterior portion of crico-thyroid muscle; 11, left lamina of thyroid cartilage cut through; 12, long thyro-epiglottic muscle (a variety); 13, inferior thyro-arytenoid; 14, thyro-epiglottic; 15, superior thyro-arytenoid; 16, median thyro-hyoid ligament. (From Krause.)

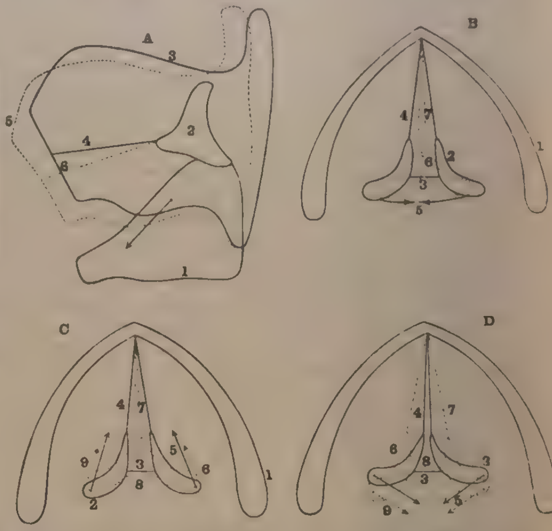

FIG. 6.—Diagrams explaining the action of the muscles of the larynx. The dotted lines show the positions taken by the cartilages and the true vocal cords by the action of the muscle, and the arrows show the general direction in which the muscular fibres act. A, Action of crico-thyroid: 1, cricoid cartilage; 2, arytenoid cartilage; 3, thyroid cartilage; 4, true vocal cord; 5, thyroid cartilage, new position; 6, true vocal cord, new position. B, Action of arytenoid: 1, section of thyroid; 2, arytenoid; 3, posterior border of epiglottis; 4, true vocal cord; 5, direction of muscular fibres; 6, arytenoid, new position; 7, true vocal cord, new position. C, Action of lateral crico-arytenoid; same description as for A and B; 8, posterior border of epiglottis, new position; 9, arytenoid in new position. D, Action of posterior crico-arytenoid; same description. (From Beaunis and Bouchard.)

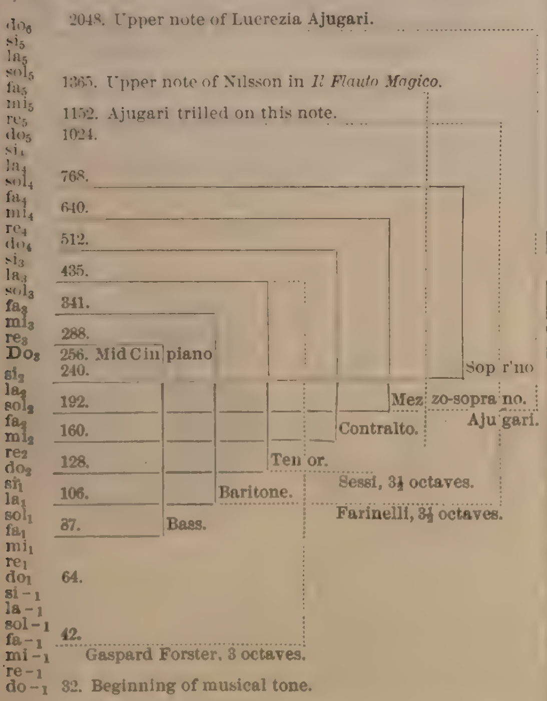
2. *General Physiological Characters.*—As already stated, the *intensity* or *loudness* of voice depends on the amplitude of the movement of the vocal cords.

Pitch depends on the number of vibrations per second; and the length, size, and degree of tension of the cords will determine the number of vibrations. The more tense the cords the higher the pitch, and the greater the length of the cords the lower will be the pitch. The *range* of the human voice is about three octaves, that is from fa$_1$ (87 vibrations per second) to sol$_4$ (768 vibrations). In men, by the development of the larynx, the cords become more elongated than in women, in the ratio of 3 to 2, so that the male voice is of lower pitch and is usually stronger. At the age of puberty, the larynx grows rapidly, and the voice of a boy "breaks" in consequence of the lengthening of the cords, generally falling an octave in pitch. A similar change, but very much less in amount, occurs at the same period in the female. At puberty in the female there is an increase of about one-third in the size of the glottis, but it is nearly doubled in the male, and the adult male larynx is about one-third greater than that of the female. In advanced life the upper notes of the register are gradually weakened and ultimately disappear, whilst the character of the voice also changes, owing to loss of elasticity caused by ossification, which first begins about middle life in the thyroid cartilage, then appears in the cricoid, and much later in the arytenoid. Eunuchs retain the voices of childhood; and by careful training it is possible in normal persons to arrest the development of the larynx so that an adult male can still sing the soprano parts sometimes used in cathedral choirs. The ranges of the different varieties of voice are shown in the following diagram, where the dotted lines give the range of certain remarkable voices, and the figures represent vibrations per second.



There is thus a range for ordinary voices of nearly two octaves, and certain rare voices may have a range of three and a half octaves. A basso named Gaspard Forster passed from fa$_{-1}$ to la$_3$; the younger of the sisters Sessi had a contralto voice from do$_2$ to fa$_5$; the voice of Catalani ranged three and a half octaves; a eunuch singer, Farinelli, passed from la$_1$ to re$_5$; Nilsson, in *Il Flauto Magico*, can take fa$_5$; and Mozart states that he heard in Parma in 1770 a singer, Lucrezia Ajugari, range from sol$_2$ to do$_6$, which she gave purely, whilst she could execute trills on re$_5$. The latter is the most highly pitched voice referred to in musical literature, an octave and a half above the highest ordinary soprano. The range of these voices is shown in dotted lines in the accompanying diagram, and the number of vibrations per second is also noted, taking the middle C of the piano as 256 vibrations per second. It will be observed that the lowest note of Gaspard Forster's voice is not much above the pitch at which the perception of musical tone begins, and that from this note to the upper note of Lucrezia Ajugari there is a range of nearly six octaves, whilst the extreme range of ordinary voices, from the lowest bass to the highest soprano, is a little over three octaves. It is also interesting to observe in connection with this that the range of the human ear for the perception of musical tone is from do$_{-1}$ to do$_{10}$, or from about 32 to 33,768 vibrations per second,—eleven octaves.

The *quality* of the human voice depends on the same laws that determine the quality, clang-tint, or timbre of the tones produced by any musical instrument. Musical tones are formed by the vibrations of the true vocal cords. These tones may be either pure or mixed, and in both cases they are strengthened by the resonance of the air in the air-passages and in the pharyngeal and oral cavities. If mixed—that is, if the tone is compounded of a number of partials—one or more of these will be strengthened by the cavities above the cords acting as a resonator; and so strongly may these partials be thus reinforced that the fundamental one may be obscured, and a certain quality or timbre will be communicated to the ear. Further, Von Helmholtz has shown that special forms of the oral cavity reinforce in particular certain partials, and thus give a character to vowel tones,—indeed to such an extent that each vowel tone may be said to have a fixed pitch. This may be proved by putting the mouth in a certain form, keeping the lips open, and bringing various tuning forks sounding feebly in front of the opening. When a fork is found to which the resonant cavity of the mouth corresponds, then the tone of the fork is intensified, and by thus altering the form and capacity of the oral cavity its pitch in various conditions may be determined. Thus, according to Von Helmholtz, the pitch corresponding to the vowels may be expressed:

Vowels..........	OU	O	A	AI	E	I	EU	U
Tone.............	fa$_2$	si$\flat_3$	si$\flat_4$	sol$_5$ or re$_4$	si$\flat_5$ or fa$_3$	re$_6$ or fa$_2$	do$_5$ or fa$_3$	sol$_5$ or fa$_2$
No. of vibrations	170	470	940	1536 or 576	1920 or 341	2304 or 170	1024 or 341	1536 or 170

Koenig has fixed the pitch of the vowels differently, thus:

Vowels....................	OU	O	A	E	I
Tone........................	si$\flat_2$	si$\flat_3$	si$\flat_4$	si$\flat_5$	si$\flat_6$
No. of vibrations.....	235	470	940	1880	3760

Donders has given a third result, differing from each of the above; and there is little doubt that much will depend on the quality of tone peculiar to different nationalities. By means of Koenig's manometric flames with revolving mirror the varying quality of tone may be illustrated: with a pure tone, the teeth in the flame-picture are equal, like the serrations of a saw, whilst usually the tone is mixed with partials, which show themselves by the unequal serrations. It is thus certain that quality of voice depends, not merely on the size, degree of elasticity, and general mobility of the vocal cords, but also on the form of the resonating cavities above, and there can be no doubt that very slight differences in these may produce striking results.

3. *Condition of the Larynx in the Various Registers.*—In singing, one can readily observe that the tone may appear to come chiefly from the chest, from the throat, or from the head, or it may show the peculiar quality of tone termed falsetto. Authorities differ much in the nomenclature applied to these varieties of the voice. Thus the old Italian music masters

spoke of the voce di petto, voce di gola, and voce di testa. Madam Seiler describes five conditions, namely, the first series of tones of the chest register, the second series of tones of the chest register, the first series of tones of the falsetto register, the second series of tones of the falsetto register, and the head register. French writers usually refer to two registers only, the chest and the head; whilst Behnke gives three registers for male voices (lower thick, upper thick, and upper thin), and five for the voices of women and children (lower thick, upper thick, lower thin, upper thin, and small).[1] These distinctions are of more importance practically than as implying any marked physiological differences in the mechanism of the larynx during the production of the tones in the different registers. By means of the laryngoscope it is possible to see the condition of the rima glottidis and the cords in passing through all the range of the voice.

In 1807 Bozzini first showed that it was possible to see into the dark cavities of the body by illumining them with a mirror, and in 1829 Babington first saw the glottis in this way. In 1854 Garcia investigated his own larynx and that of other singers, and three years later Türck and especially Czermak perfected the construction of the laryngoscope. In 1883 Lennox Browne and Emil Behnke obtained photographs of the glottis in the living man. The laryngoscope is a small mirror, about the diameter of a shilling, fixed to the end of a long handle at an angle of 125° to 130°. This mirror is gently pushed towards the back of the throat, and if sufficient light be thrown into the mouth from a lamp, and if the eye of the observer be in the proper position, by angling the small mirror it is not difficult to get a view of the glottis. The light from the lamp is reflected by the mirror down on the glottis, from this it is reflected back to the mirror, and then by the mirror it is finally reflected to the eye of the observer. Usually the observer has in front of his eye a mirror by which a powerful beam of light can be thrown from a lamp into the mouth and throat. In the centre of the mirror there is a small hole through which the eye of the observer sees the image in the small mirror at the back of the throat. By placing a second plane mirror in front of the face, an observer can easily study the mechanism of his own larynx.[2]

Suppose the picture of the larynx to be examined in the small mirror at the back of the throat, an image will be seen as in Fig. 4. During calm breathing, the glottis is lance-shaped, between the yellowish white cords. A deep inspiration causes the glottis to open widely and in favorable circumstances one may look into the trachea. When a sound is to be made, the vocal cords are brought close together, either along their whole length, as in Fig. 7, or only along the ligamentous portion, the space between the arytenoids being still open, as in Fig. 8. Then when the sound begins the glottis opens (Fig. 4), the form of the opening influencing the kind of voice, whilst the degree of tension of the cords will determine the pitch.

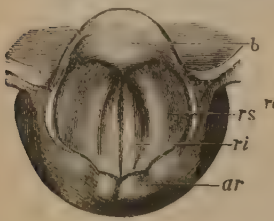


FIG. 7.

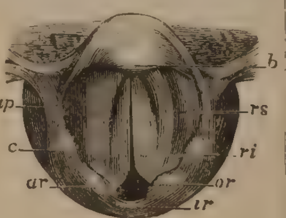

FIG. 8.

FIG. 7.—Arrangement of glottis previous to emission of a sound. *b*, epiglottis; *rs*, false cord; *ri*, true vocal cord; *ar*, arytenoid cartilages. (From Mandl.)

FIG. 8.—Closure of the ligamentous portion of glottis. *b*, epiglottis; *rs*, false cord; *ri*, true vocal cord; *or*, space between arytenoids; *ar*, arytenoid cartilages; *c*, cuneiform cartilages; *rap*, ary-epiglottic fold; *ir*, inter-arytenoid fold. (From Mandl.)

During inspiration the edges of the true vocal cords may occasionally be close together, as in sobbing, and it has been pointed out by various observers that during inspiration the false cords are easily separated, even when they touch, and during expiration, owing to dilatation of the ventricles, they come together and may readily close. Thus, from the plane of the cords, the true cords are most easily closed during inspiration and the false cords during expiration. Wyllie clearly showed in 1865 that the false vocal cords play the chief part in closure of the glottis during expiration (*Edin. Med. Jour.*, 1866). Lauder, Brunton, and Cash have confirmed Wyllie's results, and have shown further that the function of the false cords is to close the glottis and thus fix the thorax for muscular effort; and they adduce many facts from comparative anatomy in favor of this view, these cords being strongly developed in those animals whose habits render fixation serviceable, whilst, on the other hand, they are absent or weakly developed in animals where fixation is of little or no service (*Jour. Anat. and Physiol.*, vol. xvii.).

During the production of the *chest* voice, the space between the arytenoid cartilages is open, and between the vocal cords there is an ellipsoidal opening which gradually closes as the pitch of the sound rises (see Figs. 9, 10, 11). During *head* voice, the opening between the arytenoids is completely closed; the portion between the vocal cords is open, but in place of being almost a narrow straight slit as in chest voice, it is wide open so as to allow an escape of more air (see Fig. 12). The condition of the cords during *falsetto* is, according to Müller, one in which the cords can only vibrate at their margins, and especially in the middle, in consequence of the false cords pressing downwards upon them. Oertel, on the other hand, states that in falsetto the cords vibrate throughout their length, "but that they form nodal lines parallel to the free borders of the loops or bellies of vibration" (Beaunis). Probably in these circumstances

---

[1] See *Voice, Song, and Speech*, by Lennox Browne and Emil Behnke, 1883, p. 171.

[2] A cheap and efficient form of auto-laryngoscope was constructed by the late Dr. David Foulis, and may be had from Messrs. W. B. Hilliard & Son, 65 Renfield Street, Glasgow.

the membranes become much thinner. Oertel also found that during the falsetto voice the epiglottis became erect, the apices of the arytenoids were directed backwards, and the whole larynx became narrower but longer from before backwards. Behnke says that, in the production of the "small register," the mechanism "consists in the formation of an oval orifice in the front part of the glottis which contracts the more the higher the voice ascends, the vocal ligaments being, in the hinder part, pressed together so tightly that scarcely any trace of a slit remains" (Lennox Brown and Behnke, *op. cit.*). Illingworth is of opinion that falsetto (and even the ordinary voice) is produced in the "same way as the mouth is used in whistling" (see *Edin. Med. Jour.*, 1876). This view may be true to some extent as regards falsetto, but it will not hold good for the ordinary voice.

The crico-thyroid muscle is supplied by the superior laryngeal branch of the pneumogastric nerve, and all the other muscles by the inferior or recurrent laryngeal branch of the same nerve. The superior laryngeal is also the sensory nerve of the larynx. Stirling has found ganglionic cells in the course of this nerve. Paralysis of the motor fibres causes aphonia, or loss of voice. If one cord is paralyzed the voice may be lost or become falsetto in tone. Sometimes the cords may move in breathing or during coughing, but be motionless during an attempt at the production of voice. Rarely, incomplete unilateral paralysis of the recurrent nerve, or the existence of a tumor on each cord, thus making them unequal in length, may cause a double tone, or *diphthongia* (Türck). Hoarseness is caused by roughness or swelling of the cords.

On the history of the theories of voice production, see Longet's *Traité de Physiologie*, 1869, vol ii. p. 733, and Gavarret's *Phonation et Audition*, 1877, p. 541. An excellent bibliography is given in Beaunis's *Physiologie Humaine*, 1881, vol. ii. p. 946; also in Quain's *Anatomy*, 1882, vol. ii. p. 538. (J. G. M.)

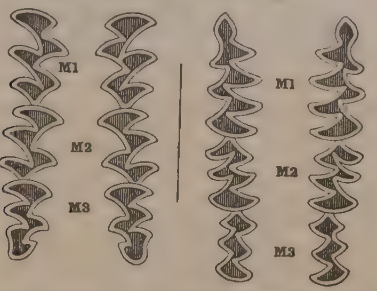
VOIRON, a manufacturing town of France, in the department of Isère, stands on the banks of the Morge (a tributary of the Isère) and on the lower slopes of a mountain nearly 2500 feet high, 15 miles north-north-west of Grenoble on the Lyons railway. Some 30 or 35 factories, employing from 4000 to 5000 persons, are engaged in the production of a kind of cloth that takes its name from the town (toiles de Voiron), and the industry is carried on in the neighborhood also, every inhabitant having his loom. Table linen, silk stuffs (2000 looms), and liqueurs are also made, and there are paper-mills, bleachworks, foundries, edge-tool factories, and building sheds. The monks of La Grande Chartreuse have stores at Voiron in connection with the railway. A fine modern church was built from 1864 to 1873 in the style of the 13th century. The chief attraction of the town lies in the fine views it possesses of the mountains of Grenoble and the valley of the Isère. The population in 1886 was 8575.

VOITURE, Vincent (1598–1648), the best writer of *vers de société* that France has yet produced, and one of the most influential preceptors of classical French prose, was born at Amiens in 1598. His father was a well-to-do wine merchant, who had connections with the court, and it is one of the charges brought against Voiture that he was unnecessarily ashamed of his origin. At any rate he soon obtained a position in society, being appointed by Gaston d'Orléans to various offices in his household. Voiture had been well educated, and had profited both by his education and by the school friendships which it enabled him to make. He was early introduced to the Hôtel de Rambouillet, and travelled in the suite of Monsieur, or on missions, a good deal both in and out of France, on one occasion extending his journeyings as far as Ceuta, whence he wrote a letter of elaborate gallantry to Mademoiselle Paulet. Although a follower of Gaston, he made friends with Richelieu, and was one of the earliest Academicians. He also received appointments and pensions from Louis XIII. and Anne of Austria, and became altogether a very prosperous person. During his lifetime he, like most of the literary men of his time who were not either dramatists or serious scholars, published nothing in book form, but his verses and his prose letters were the delight of the coteries, and were copied, handed about, and admired more perhaps than the work of any contemporary. This coterie success has, it would seem, done them more harm than good in the eyes of posterity. When the long and rather wearisome history of the quarrel between the Uranistes and the Jobelins (partisans of the respective merits of a sonnet of Voiture addressed to a certain Uranie and of another composed by his younger rival Benserade on the subject of Job) is mentioned, the modern reader is apt to suppose that the interest of the affair is merely one of antiquarian gossip. Yet it is difficult to think of any living writer who could surpass, or of any writer living during the last two centuries who could have surpassed, the mixture of gallantry and sincerity in the Uranie sonnet. Another famous piece of his of the same kind, "La Belle Matineuse," is less exquisite, but still very admirable, and, generally speaking, Voiture deserves the praise given to him at the head of this article. His prose letters, if less interesting to the present generation, are full of lively wit, and are historically even more important. He ranks with Jean de Balzac as the chief director of the reform in French prose which accompanied that of Malherbe, and preceded that of Corneille, in French verse. Nor is there any one to whom more than to Voiture (who was for many years almost an *arbiter elegantiarum* in literary matters) the escape of French prose from the over-legislation which had such injurious effect on French verse can be ascribed. The fault of the century—a tendency to elaborate and "metaphysical" turns of phrase—affected him to a certain extent, but in a mild form; and, on the whole, he was the Frenchman of letters of the old school who has been least favorably treated by the resurrection of taste for that old school which the present century has seen. It may seem absurd, but is probably just, to ascribe this absence of enthusiasm in part to the fact that the most unjust censures of the extreme classical school passed harmless by him. Boileau had no abuse for him, and the 18th century read him with pleasure. The militant spirit of Romanticism had therefore nothing to avenge. Voiture lived a careless and Epicurean life for just fifty years, and died at the outbreak of the Fronde, which killed the society to which he was accustomed, on the 26th of May, 1648. His works were first published two years later, and a characteristic and rather absurd literary quarrel, which made a great noise at the time, broke out, on the subject of his literary merits, between his friend Costar and a certain Sieur de Griac. The standard modern edition of Voiture is that of Ubicini, 2 vols., Paris, 1855.

VOLCANOES. See Geology, vol. x. pp. 199, 217–226.

VOLE (Germ. *Wühlmaus*, Fr. *Campagnol*). This word, little known as it is to the majority of English people, is the proper name for a genus containing three of the commonest of our English mammals, namely, the water, bank, and field voles,—animals generally called "water-rat," "red field-mouse," and "short-tailed field-mouse" respectively. The scientific name for the group is *Arvicola*, a genus which, with the lemmings and two or three other genera, forms the sub-family *Arvicolinæ* of the great Rodent family *Muridæ*, whose proper place in the general system is shown under Mammalia (vol. xv. p. 424).

The voles, as a whole, are distinguished by their squat and heavy shape, their slower and less graceful movements, very small eyes, blunt snout, inconspicuous ears, and shortened limbs and tail, in all of which points they are markedly contrasted with the true rats and mice of the genus *Mus*, the only animals with which they can be confounded. But by far the most important characteristic of the voles lies in their molar teeth, which have been said to form "the perfection of Rodent dentition" from their wonderful specialization and adaptation to the purpose of grinding vegetable substances. These teeth, three in number on each side of each jaw, are rootless, that is to say, they go on growing during the whole life of the animal at the same rate that they are worn down by use, just as is the case with the incisors, whose rootless condition is a characteristic of the whole Rodent order. Each tooth consists of a variable number of prismatic pillars formed externally of enamel and internally of the softer dentine, their section, as produced naturally by wear, being as is shown in the woodcut, a figure which may be compared with that given of the true murine dentition under MOUSE (vol. xvii. p. 11). The general prismatic appearance of the teeth, however, is only due to the bending in at regular distances of the external enamel walls of the tooth, to such an extent that the enamel touches that at the opposite side of the tooth and thus shuts off a greater or less number of dentinal spaces, triangular in section. Owing to the manner of growth of the teeth their general pattern of spaces and angles is but little affected by age and wear, remaining practically the same throughout the life of the animal. On this account the variations in the pattern have been very generally used as a means of characterizing the different genera, subgenera, and species of the group, although their value for this purpose has of late been questioned, and a new classification proposed, entirely ignoring the tooth-characters, and based more upon external peculiarities.



Molars of Water-Vole (*Arvicola amphibius*) ; top view.

Without entering into the characters of the different sub-groups of the voles, it may suffice to say that each of the three species found in Great Britain belongs to a distinct subgenus of *Arvicola*, and therefore the three together give a fair idea of the extent to which the subgenera differ from one another. These three species are the following:

1. The common Water-Vole (*Arvicola amphibius*) is as large as the house-rat, with which it is so often confused, but possesses of course the bluff-headed appearance and short tail characteristic of the voles. Its fur is long, soft, and thick, of a uniform grizzled brown all over, except when, as is not uncommon, it is wholly black. Its tail is about half the length of its head and body, and its hind feet are usually long and powerful, although not webbed, and have five rounded pads on their lower surfaces. Its molar teeth (see woodcut) present the following number of prismatic spaces: in the upper jaw the first, or anterior, has 5, the second 4, and the third 4, of which the last is very irregular in shape, and is sometimes itself divided into two making 5 in all; in the lower jaw the first has 7 spaces, of which the 3 anterior are generally not fully separated from one another, the second has 5, and the third 3. These numbers for the different teeth are taken as the characters of the subgenus *Paludicola* of Dr. Blasius, by whom this method of subdividing the group was first introduced. The water-vole is one of the commonest English mammals, and is perhaps the most often actually seen of all, owing to its diurnal instead of nocturnal habits. It frequents rivers and streams, burrowing deeply into their banks, and in this way often causing considerable damage. Its food consists almost wholly of water-weeds, rushes and other vegetable substances, but, like so many other rodents, it will also eat animal food on occasion, in the shape of insects, mice or young birds. The female has during the warm season of the year three or four litters, each of from two to seven young. The range of the water-rat extends over the whole of Europe and North Asia, from England to China, but is not found in Ireland, where curiously, no species of *Arvicola* is indigenous.

2. The next British species, representing the subgenus *Agricola* of Dr. Blasius, is the common Field-Vole, or short-tailed field-mouse (*Arvicola agrestis*), about the size of a house-mouse, but with a short stumpy body, and a tail only about one-third the length of the head and body combined. Its hind feet have six pads on their inferior surfaces. Its color is dull grizzled brown above, and grayish-white below. Its molar teeth have respectively 5, 5, and 6 prismatic spaces above, and 9, 5 and 3 below. The field-vole is one of the commonest of our smaller mammals, and frequents fields, woods and gardens in enormous numbers, often doing very considerable damage in the latter owing to its fondness for garden produce of all kinds. It is spread over the whole of Great Britian from the Hebrides southwards. Abroad its range extends from Finland to North Italy and from France and Spain to Russia.

3. The Bank-Vole (*Arvicola glareolus*) is of much the size and general appearance of the common field-vole, but may be distinguished by its more or less rusty or rufous-colored back, its larger ears, and its comparatively longer tail, which attains to about half the length of the head and body. Its molar teeth present characters so different from those of all other voles as to have caused it to be often looked upon as belonging to an entirely distinct genus, for which the name of *Evotomys* is used. Their chief distinction lies in the fact that, unlike those of all other voles, their pulp-cavities close up in adult life, and they form distinct roots, more resembling those of the ordinary rats and mice. The enamel spaces of these teeth number respectively 5, 4 and 5 above, and 7, 3 and 3 below. The habits of this species are in every way similar to those of the field-vole. Its range in Great Britain extends northwards to Morayshire, beyond which it has not yet been observed. Abroad it is found all along the north temperate zone from France to China, and is replaced in North America by a closely allied animal known as *Arvicola gapperi*. It is probable, however, that both these forms, *A. gapperi* and *A. glareolus*, are only southern climatic offshoots of a still more northern species, the *Arvicola rutilus* of northern Europe, Siberia and Arctic America.

The foreign species of vole number about 40, of which about 10 are European, 20 Asiatic, and 10 North American, none being found either in Africa, India (except in the extreme north), Australia or South America. The group is therefore one peculiarly characteristic of the temperate parts of the northern hemisphere. (O. T.)

VOLGA, THE, the chief river of European Russia, rises in the Valdai plateau of Tver in northwestern Russia, and after a winding course of 2325 miles (1040 in a straight line) falls into the Caspian at Astrakhan. It is by far the largest river of Europe, those next in length, the Danube and the Ural, being only 1735 and 1478 miles respectively, while the Rhine (825 miles) is shorter even than two of the chief tributaries of the Volga,—the Oka and the Kama. Its drainage area, which includes the whole of middle and eastern as well as part of southeastern Russia, amounts to 563,300 square miles, thus exceeding the aggregate superficies of Germany, France and the United Kingdom. A hundred tributaries of the Volga are navigable for an aggregate length of 14,600 miles, a distance greater than the aggregate length of all the railways of England and Wales. The drainage area embraces twenty-one provinces of the Russian empire, or, in other words, nearly the whole of Great Russia proper, and has a population of nearly 40,000,000. The most populous regions of Great Russia are situated within the Volga basin, and cities like Moscow, Nijni-Novgorod, Saratoff, Simbirsk and Kazañ, as well as many others, are indebted for their growth and present importance to their situation on the Volga or its tributaries. But the real "basin" of the Volga is not limited to its drainage area. By a system of canals which connects the Upper Volga with the Neva, the commercial

See vol. xxi. Plate II.

mouth of the Volga has been transferred, so to speak, from the Caspian to the Baltic, thus making St. Petersburg, the capital and chief seaport of Russia, the chief port of the Volga basin as well. Other less important canals connect it with the Düna and the White Sea (Riga and Archangel); while a railway only 40 miles in length joins the Volga with the Don and the Sea of Azoff, and three great trunk lines bring its lower parts into connection with the Baltic and western Europe. Traffic on the river and its tributaries is carried on by more than 760 steamers, 20,000 barges and boats, and 50,000 rafts; upwards of 4,000,000 tons of various goods, valued at 500,000,000 roubles [$385,000,000] (in weight one-half and in value three-fourths of the total merchandise on Russian rivers) are carried. If in addition some 50,000 rafts of timber not included in the preceding statistics are reckoned, the timber floated in the basin of the Volga exceeds by nearly a million tons the total weight of merchandise carried on the 13,000 miles of Russian railways.[1]

The Volga rises in the extensive marshes covering the western parts of the Valdai plateau, where the Düna also has its origin. Small streamlets languidly circulate from marsh to marsh, so that it is very difficult to say which of these ought to be regarded as the real source. Lake Seliger was formerly so considered; but at present that distinction is given to a small spring trickling into a wooden trough from beneath a small chapel in the midst of an extensive marsh to the south of Seliger (57° 10′ N. lat.). The honor has also been claimed of late, not without plausibility, for the Runa rivulet.[2] Recent exact surveys have shown those marshes to be no more than 665 feet above sea-level. The stream first traverses several small lakes, all having the same level, and, after its junction with the Runa, enters Lake Volgo. A dam recently erected a few miles below that lake, with a storage of 350 million cubic yards of water, makes it possible to raise the level of the Volga as far as the Sheksna, thus rendering it navigable, even at low water, from its 65th mile onwards. Unlike most other great rivers, the Volga has thus no "upper course" among the mountains. From the Valdai plateau, however, its descent is rapid, until at Tver its level is only 420 feet. Before reaching this point it has received numerous small tributaries, so as to be already 300 yards in breadth, with a volume of more than 4000 cubic feet per second, and a minimum depth at low water of 19 inches. The Tvertsa is connected by the Vyshniy-Vołotchok Canal with the Tsna, a tributary to the Msta and Volkhoff, which flows to Lake Ladoga,—the first of the three systems of canals which, as already remarked, have removed the commercial mouth of the Volga to the Baltic. From Tver the Volga is regularly navigated, although not without some difficulties on account of the shallows and sandbanks. It flows northeast along a broad valley to join the Mołoga and the Sheksna, two important tributaries connected by the Tikhvinsk and Mariinsk Canals with the tributaries of Lake Ladoga. Of these two systems the latter is much the more important, and the town of Rybinsk, at the mouth of the Sheksna, has therefore become the chief port of the upper Volga.

From its junction with the Sheksna the Volga flows with a very gentle descent towards the southeast, past Yarosłavl and Kostroma, along a broad valley hollowed to a depth of some 150 and 200 feet in the Permian and Jurassic deposits. In fact, its course is through a succession of depressions formerly filled with wide lakes, and connected by links. When the Volga assumes a due southeast direction it is already a large river (8250 cubic feet per second, rising occasionally in high flood to as much as 178,360 cubic feet); of its numerous tributaries, the Unzha (365 miles, 330 navigable), from the north, is the most important.

The next great tributary is the Oka, which comes from the southwest after having traversed, on its course of 920 miles, all the Great Russian provinces of central Russia. It rises in Orel among hills which also send tributaries to the Dnieper and the Don, and receives on the left the Upa, the Jizdra, the Ugra (300 miles), navigable up to Kozelsk, the Moskva, on which steamers ply up to Moscow, the Klyazma (395 miles), on whose banks arose the Middle Russian principality of Suzdal, and on the right the navigable Tsna (255 miles) and Moksha. Every one of these tributaries is connected with some important event in the history of Great Russia, and the drainage area of the Oka is a territory of 97,800 square miles. It has been maintained of late that, of the two rivers which unite at Nijni-Novgorod, the Oka, not the Volga, is the chief; and the fact is that both in length (818 miles) and in drainage area above the junction (89,500 square miles), as well as in the aggregate length of its tributaries, the Volga is the inferior. But on the other hand, the Volga contributes on the whole the largest volume of water, although in flood the Oka here also has the advantage.

At its junction with the Oka the Volga enters the broad lacustrine depression (see RUSSIA) which must have communicated with the Caspian during the Post-Pliocene period by means of at least a broad strait. Its level at low water is only 190 feet above that of the ocean. Immediately below the junction its breadth ranges from 350 to 1750 yards, and even at the lowest water (in 1873) it had a minimum depth of 5½ feet. The valley, which is nearly 7 miles wide, but at several places is narrowed to less than 2 miles, shows evident traces of having originated from a succession of elongated lakes, the shores of which bear numerous traces of the dwellings of prehistoric man from the Stone Age. There are many islands which change their appearance and position after each inundation. On the right it is joined by the Sura, which drains a large area and brings a volume of from 2700 to 22,000 cubic feet of water per second, the Vetluga (465 miles long, of which 365 are navigable), from the forest-tracts of Yarosłavl, and many smaller tributaries; then it turns southeast and descends to another lacustrine depression, where it receives the Kama below Kazañ, 300 miles below its junction with the Oka, and only 110 feet above the sea. Remains of molluscs still extant in the Caspian occur extensively throughout this depression and up the lower Kama.

The Kama which brings to the Volga a contribution ranging from 52,500 to 144,400 cubic feet and occasionally reaching even 515,000 cubic feet per second, might again be considered as the more important of the two rivers. It rises in Vyatka, takes a wide sweep towards the north and east, and then flows south and southwest to join the Volga after a course of no less than 1120 miles. A great number of important rivers join it: the Wishera, coming from the depth of the forest region; the Kosva, so important for the export of metallic wares from the Ural works; the Tchusovaya (430 miles), which receives the Sylva and connects the Ekaterinburg mining district with central Russia; and finally the Byełaya (800 miles), which, together with the Ufa, its tributary, waters the fertile lands of the Bashkirs, rapidly being settled now by the Russians. A territory larger than France is thus brought into connection with the great artery of Russian industrial life.

Along the next 738 miles of its course the Volga—now from 580 to 2600 yards wide, flows south-southwest with but one great bend at Samara. At this point, where it pierces a range of limestone hills, the course of the river is very picturesque, fringed as it is by high cliffs which rise about 1000 feet above the level of the water (which is only 54 feet above the sea at Samara). Along the whole of the Samara bend the Volga is accompanied on its right bank by high cliffs, which it is constantly undermining, while wide lowland areas extend on the left or eastern bank, and are intersected by several old beds of the Volga. At SARATOFF (*q.v.*) the cliffs are being undermined so rapidly that a broad beach now separates the chief channel of the river from the city. Very few streams of any importance join the Volga in this part of its course. Still, at Ekaterinenstadt, a few miles above Saratoff, the volume per second for the two years 1884 and 1885 appears to have been as much as 384,000 cubic feet. In flood 1,427,000 cubic feet per second has been recorded (Boguslavskiy). In the lower portion of this section the Volga has already passed below sea-level (58 feet below at Tsaritsyn).

At Tsaritsyn the Volga reaches its extreme southwestern limit, where it is separated from the Don by an isthmus of only 40 miles in width. The isthmus is too high to be crossed by means of a canal, but a railway at Duboffka brings the Volga into some sort of connection with the Don and the Sea of Azoff. At Tsaritsyn the river takes a sharp turn in a southeasterly direction towards the Caspian; it enters the Caspian steppes, and some 50 miles below Tsaritsyn sends off a branch—the Akhtuba—which accompanies it for 330 miles before falling into the Caspian. Here the Volga receives no tributaries; its right bank is skirted by low hills, but on the left it spreads freely, joining the Akhtuba by many branches when its waters are high, and

[1] See "The Volga as a Means of Communication," by Prof. Boguslavskiy, St. Petersburg, 1887 (Russian), being vol. ix. of the *Sbornik* of the Institute of Roads and Communications. The above length of the Volga is taken from this work, based on recent surveys, and is therefore more accurate than the length given by M. Strelbitzky (1978 miles) and Gen. Tillo (2108 miles).

[2] Ragozin, *The Volga*, St. Petersburg, 1881, 3 vols. (Russian), summarized in Roskoschny's *Die Wolga und ihre Zuflüsse*, Leipsic, 1887.

flooding the country for from 15 to 35 miles. The width of the main branch ranges from 520 to 3500 yards, and the depth exceeds 80 feet. The delta proper begins 40 miles above Astrakhan, and the branches subdivide so as to reach the sea by as many as 200 separate mouths. Below Astrakhan navigation is difficult, and on the sand-bars at the mouth the maximum depth is only 12 feet in calm weather, —a depth increased or diminished by a few feet according to the force and direction of the wind.

The figures given above, showing as they do how immensely different in volume is the river at different periods, help to indicate the greatness of the changes which are constantly going on in the channel and on its banks. Not only does its level occasionally rise in flood as much as 50 feet and cover its low-lying banks for a distance ranging from 5 to 15 miles; even the level of the Caspian is considerably affected by the sudden influx of water brought by the Volga. The amount of suspended matter brought down is of course correspondingly great; and, were it not for the action of the wind in driving back masses of water at the mouth of the Volga and thus filling up lakes where the mud is deposited, the bar at Astrakhan would soon become so silted up as completely to prevent navigation. All along its course the Volga wastes its banks with great rapidity; towns and loading ports have constantly to be shifted farther back. The shoals and shallows are continually changing, and maps of the river made for a series of consecutive years are of the greatest interest to the physical geographer.

The question as to the gradual desiccation of the Volga, and its causes, has often been discussed, and in 1838 a committee which included Karl Baer among its members was appointed by the academy of sciences to investigate the subject; no positive result has, however, been arrived at, principally on account of the want of regular measurements of the volume of the Volga and its tributaries,—measurements which began to be made on scientific principles only in 1880. Still, it may be regarded as established that during the last thirty years new shallows have appeared in the upper Volga, and the old ones have increased in size; while if we go back two or three centuries it is indisputable that rivers of the Volga basin which were easily navigable then are now hardly accessible to the smallest craft. The desiccation of the rivers of Russia has been often attributed to the steady destruction of its forests. But it is obvious that there are other general causes at work much more important,—causes to which the larger phenomena of the general desiccation of all rivers of the northern hemisphere in the deserts of Siberia and Turkestan, as well as in Russia, must be attributed. The gradual elevation of the whole of northern Russia and Siberia, and the consequent draining of the marshes (see NOVGOROD), is one of them; the drying-up of lakes all over the northern hemisphere, a process which is going on so rapidly (see TOMSK), in consequence of the deepening of the outflows of lakes and the cessation of supply to the lakes which remained after the glaciation of the northern hemisphere, is another; and both causes are amply sufficient to explain the known phenomena throughout the historical period. The desiccation of the Russian rivers is only one instance of the general desiccation of the northern parts of the Old World, of which so many instances have been given under RUSSIA, TURKESTAN, TRANSCASPIAN REGION, and SIBERIA.

Fisheries.—The network of shallow and still *limans* or "cut-offs" in the delta of the Volga and the shallow waters of the northern Caspian, sweetened as these are by the water of the Volga, the Ural, the Kura, and the Terek, is exceedingly favorable to the breeding of fish, and as a whole constitutes one of the richest fishing grounds of the world. As soon as the ice breaks up in the delta innumerable shoals of roach (*Leuciscus rutilus*) and trout (*Luciotrutta leucichthys*) rush up the river. They are followed by the great sturgeon (*Acipenser huso*), the pike, the bream, and the pike perch (*Leucioperca sandra*). Later on appears the Caspian herring (*Clupea caspia*), which formerly was neglected, but has now become more important than the various species of sturgeon; the sturgeon (*A. stellatus*) and "wels" (*Silurus glanis*, see vol. xxii. p. 74) follow, and finally the sturgeon *Acipenser güldenstädtii*, so much valued for its caviare. In search of a gravelly spawning-ground the sturgeons go up the river as far as Sarepta (250 miles). The lamprey, now extensively pickled, the sterlet (*A. ruthenus*), the tench, the gudgeon, and other river species also appear in immense numbers. No less than 15,000 men, partly from central Russia, are engaged in the fisheries of the lower Volga and its delta, while on the waters of the northern Caspian there are as many as 3000 fishing-boats, giving employment to something like 50,000 persons. From the end of June onwards immense trawl-nets, sometimes a mile in length, and occasionally taking at one haul as many as 40,000 bream, 150,000 roach, and 200,000 herrings, are continually at work, and it is estimated that 3,600,000 cwts. of various fish, of the value of 15,000,000 roubles, [$11,550,000] are taken annually in the four fishing districts of the Volga, Ural, Terek, and Kura. Seal-hunting is also carried on off the Volga, and every year about 40,000 of the *Phoca vitulina* are killed to the north of the Manghishlak peninsula. Fishing is extensively carried on along the entire course of the Volga and its tributaries, as also in the lakes of its upper basin.

Ice-Covering.—In winter the numberless tributaries and sub-tributaries of the Volga become so many highways for sledges. The ice lasts from 90 to 160 days according to the climatic conditions, and breaks up earlier in its upper course than in some parts lower down. The average date of the break-up is April 11th at Tver, and 14 days later about Kostroma, from which point a regular acceleration is observed (April 16th at Kazañ, April 7th at Tsaritsyn, and March 17th at Astrakhan). Similarly, the average dates of freezing are November 23d at Tver, November 20th about Kostroma, December 7th at Kazañ, 20th at Tsaritsyn, and 17th at Astrakhan. Thus the river is open for an average of 226 days at Ostashkoff and Tver, 215 days at Kostroma, and 209 at Kineshma; from Nijni-Novgorod, where the average is 224 days, there is a regular increase (235 days at Kazañ, 241 at Samara, 257 at Tsaritsyn, and 275 at Astrakhan). There are, however, great fluctuations, the navigation in some years having lasted only 182 days in the upper course, 169 at Kostroma, and 243 at Tsaritsyn; while within the last eighty years maxima of 260 days in the upper course and 288 in the lower course have been observed. The tributaries are navigable for periods ranging from 180 to 246 days.

Traffic.[1]— The chief Volga traffic is up river, the amount of merchandise which reaches Astrakhan being nearly fifteen times less than that reaching St. Petersburg by the Volga canals. The details of this traffic are highly characteristic of the present economic life of Russia. Ten million cwts. of fish, salt and naphtha are despatched from Astrakhan; this contingent is soon swelled to 12 millions at Tsaritsyn by the salt brought by rail from the Baskuntchak salt-lakes. From Tsaritsyn 7 million cwts. of fish, salt, and naphtha are despatched by the first of the three railways which traverse Russia from southeast to northwest and connect the lower Volga with the Baltic. Considerable amounts of corn are added to this total on its way towards the northwest; and, while salt, fish, and naphtha are discharged for use at various points in middle Russia, the flow of corn continues to swell; portions of it are sent to Moscow from Gryazi and Orel, but the remainder goes northwest, so as to reach Riga to the amount of 9,300,000 cwts., chiefly of corn and flax.

By the Volga itself only 5,100,000 cwts., chiefly of fish, salt, and naphtha, leave Tsaritsyn, but before this ascending traffic reaches Saratoff it has increased to 6,300,000 cwts., chiefly by the addition of corn from the Saratoff steppes. There the current of merchandise divides again; 3 million cwts. of corn, fish, etc., leave the Volga to be carried northwestwards towards Tamboff, while the remainder is carried on farther north, up the Volga, receiving on the way considerable additions of corn from the fertile tracts of Samara and the steppes of Orenburg, which are connected with Samara by rail. At Samara the flow again divides, and part of it is sent again northwest *via* Penza, to Ryazhsk; there the three northwestern currents which leave the Volga respectively at Tsaritsyn, Saratoff, and Samara reunite after having taken in corn from the fertile regions of Tamboff and Ryazañ, so that nearly 20 million cwts. of corn and other produce leave Ryazhsk to be carried on to Moscow. But the flow of corn ascending the Volga does not diminish, and Samara sends farther north no less than 14 million cwts., chiefly corn. At Kazañ the volume of traffic is 16,200,000 cwts., (13 million cwts. of corn). Here a new mass consisting of 11 million cwts. of corn, 3½ of various metals, 4 of salt, and 6½ of miscellaneous merchandise, all shipped down the Kama, joins the former, so that the total amount of merchandise forwarded from Kazañ up the Volga reaches 35 million cwts. The Sura, the Oka, and the Vetluga add their corn, timber, and manufactured goods, and the volume reaching Nijni-Novgorod amounts to 38 million cwts. Here the stream divides once more: while manufactured goods brought in to the Nijni-Novgorod fair are dispersed from it all over Russia, nearly 10 million cwts. of various merchandise (4 million of corn) are sent by rail to Moscow, but the great bulk (28 million cwts.) continues to move up the river, receiving on the way more timber from the Unzha, and sending some corn northwards to Vologda and Archangel.

[1] See *Sbornik* of the Ministry of Roads and Communications, vols. xi. and xii., 1885 and 1887: Graphical Maps of the Movement of Goods in 1882 and 1883.

When the traffic reaches Rybinsk, we find that it consists of 20 million cwts. of corn and flax, and 5½ million of metals, metallic and manufactured goods, hides, leather, and so on. At Rybinsk it again subdivides into three branches; one (6,300,000 cwts., chiefly of corn) is discharged and sent by rail to St. Petersburg; another (2,800,000 cwts.) continues up the Volga to enter the Vyshniy Vołotchok and Tikhvinsk canal-systems; and the third and largest (16 million cwts., almost entirely corn and flax) moves along the Mariinsk system towards Lake Ladoga and St. Petersburg. Masses of timber and wood for fuel are added to it from the forest tracts of the lake district,—the Syas and the Volkhoff bringing together nearly 17 million cwt., chiefly wood, so that finally 14,000,000 cwts. of corn and flax, 31,300,000 of timber and wood, 16,000,000 of building materials, and 4,000,000 of miscellaneous goods reach St. Petersburg, which thus is the real seaport of the Volga basin.

The goods traffic down the river is much less important in weight, but relatively greater in value. Its prominent feature is the amount of wood sent to supply the provinces of Samara, Saratoff, and Astrakhan, as well as the lower Don, which now have very few or no forests. But the 8½ million cwts. of wood and timber which reach Samara on boats are but a trifle in comparison with what is floated in the shape of rafts. The down traffic in manufactured goods is still more important. The great bulk of those exported from St. Petersburg is sent to Moscow by rail, and thence distributed by rail over central Russia; but part of it is sent by rail to Rybinsk, and thence shipped down the Volga. Moscow sends its goods for the same purpose, partly to Yarosłavl, and partly to Nijni-Novgorod (by rail), as also does Vladimir. Nijni-Novgorod distributes the merchandise all over eastern Russia, sends it up the Kama to Siberia, and ships nearly 2 million cwts. down the Volga. This quantity is increased by the additions brought by rail to Samara, Saratoff, and Tsaritsyn.

According to official returns the aggregate amount of goods loaded in the basin of the Volga amounts to nearly 4 million tons, valued at 150 million roubles [$115,500,000.00] (2 million tons, 100 millions [$77,000,000.00] worth, on the Volga proper); trustworthy authorities, however, consider the real value of goods loaded in the basin of the Volga to be not less than 500 million roubles [$385,000,000.00], exclusive of nearly 34 million tons of timber and fuel.

Formerly tens of thousands of "burłaki" were employed in dragging boats up the Volga and its tributaries, but this method of traction has disappeared unless from a few of the tributaries. Horse-power is still extensively resorted to along the three canal systems. The first large steamers of the American type were built in 1872. Steamers are now very common; in 1885 as many as 766 were already in use on the Volga and its tributaries, and of these only one-eighth were not built within the Volga basin itself. One-third of them use naphtha as fuel. Of barges and other light vessels an immense variety of types are now in use; during 1885 no fewer than 20,610 vessels were afloat, and during the last thirteen years the annual average of vessels built on the Volga and its tributaries has been 5030 (4,130,000 roubles [$3,180,000.00]). Large numbers of them are broken up after a single voyage.

History.—The Volga was not improbably known to the early Greeks, though it is not mentioned by any of the writers previous to Ptolemy, who all confounded the Caspian with a gulf of the Arctic Ocean. According to Ptolemy, the Rha is a tributary of an interior sea, formed from the confluence of two great rivers, the sources of which are separated by twenty degrees of longitude; but it is scarcely possible to judge from his statements how far the Slavonians had by that time succeeded in penetrating into the basin of the Volga. The Arabian geographers also throw but little light on the condition of the Volga (which they knew, under the names of Itil, Etil, or Atel) during the great migrations of the 3d century, or subsequently under the invasion of the Huns, the growth of the great Khazar empire in the southern steppes, and of that of Bulgaria on the middle Volga. But we know that in the 9th century the Volga basin was occupied by Finnish stems in the north, and by Khazars and various Turkish stems in the south. The Slavonians, driven perhaps to the west, had only the Volkhoff and the Dnieper, while the Mohammedan Bulgarian empire, at the confluence of the Volga with the Kama, was so strong that for some time it was an open question whether Islam or Christianity was to gain the upper hand among the Slavonian idolaters. But, while the Russians were driven from the Black Sea by the Khazars, and later on by a tide of Ugrian migration from the northeast to the southwest (see p. 9 *supra*), a stream of Slavonians slowly moved towards the northeast, down the Oka, into the borderland between the Finnish and Turkish stems. After two centuries of struggle the Russians succeeded in colonizing the fertile valleys of the Oka basin; in the 12th century they built a series of fortified towns on the Oka and Klyazma, and finally they reached the mouth of the Oka, there founding (in 1222) a new Novgorod—the Novgorod of the Lowlands, now Nijni-Novgorod. The great lacustrine depression of the middle Volga was thus reached. Under the protection of the forts in the northeast, of the forests of Ryazañ in the south, and of the marshes of Novgorod and Tver in the north, the Great-Russian nationality freely developed in the fertile valleys of the Oka, absorbing the feeble Finnish tribes which formerly peopled them; and when the Tartar-Mongolian invasion came it encountered in the Oka basin a dense agricultural population with many fortified and wealthy towns,—a population which the Mongols found they could conquer, indeed, but were unable to drive before them as they had done with so many of the Turkish stems. This invasion only checked but did not stop the further advance of the Russians down the Volga; nay, it partly facilitated it, because it weakened the Bulgarian empire, and, by keeping up on the lower Volga a continual flow and ebb of nomads, prevented the development there of any settled population which might ultimately have opposed the further advance of the Russians towards the Caspian. Two centuries elapsed before the Russians covered the 300 miles which separate the mouths of the Oka and the Kama, and took possession of Kazañ. But in the meantime a flow of Novgorodian colonization had moved eastward, in the upper portions of the left bank tributaries of the Volga, and had reached the Urals, thus opening the way to Siberia.

With the capture of Kazañ the Russians found the lower Volga open to their boats, and eight years afterwards they were already masters of the mouth of the river at Astrakhan. The Tartars and Turks of the steppes between the Dnieper and the Volga were thus encircled; the Little Russians endeavored to take possession of the lower Dnieper, and the Great Russians already had a firm footing on the lower Volga. The possession of the latter opened a free passage to the Don, up the little river Kamyshinka (now dried up but then navigable), which gave easy means of crossing the narrow isthmus between the Don and the Volga. Thus the lower Don was colonized. But two centuries more elapsed before the Russians opened for themselves a free passage to the Black Sea and became masters of the Sea of Azoff and the Crimea; the Volga, however, was their route. During these two centuries they fortified the lower river, settled it, and penetrated also farther eastward into the steppes, towards the upper Ural and thence to the upper parts of the Tobol and the other great Siberian rivers. They penetrated also into the northern parts of the Caucasus isthmus, while another stream of armed colonization moved up the Kama and its numerous tributaries; finding the sources of these close to those of the Ob and Tobol, they crossed the low watersheds of the Urals and spread over northern Siberia, always following the river courses and taking advantage of the portages for penetrating from one basin into the next. The entire growth of Russia towards the east went on from the Volga and its tributaries, and the long line of water communication (nearly 1000 miles) which flows from the upper Kama (60° N. lat.) to Astrakhan (46° 4′), between Europe and Asia, and extends as far south as Astrabad on the Caspian (36° 51′ N. lat.), became the basis for all further advance of Russia into Asia.

Bibliography.—Semenoff's *Geographical and Statistical Dictionary*, 5 vols., 1863-1885, contains a full bibliography of the Volga and tributaries up to date. See also Baer's *Kaspische Studien*, 1837 *sq.*, Haxthausen's *Studien über Russland*; Baer and Helmersen's *Beiträge*; *Spiski naselennykh myest* of Volga provinces; V. For geology, see the publications of the Geological Committee and Mineral Society (maps of Yarosłavl and lower Volga), and *Memoirs* of Astrakhan Statistical Committee for fishing. (P. A. K.)

VOLHYNIA, a government of southwestern Russia, bounded by the Polish provinces of Lublin and Siedlce on the W., Grodno and Minsk on the N., Kieff on the E., and Podolia and Galicia (Austria) on the S., has an area of 27,731 square miles. A broad and flat spur of the Carpathians—the Avratynsk plateau—

which enters from the west and spreads eastward towards the Dnieper, occupies its southern portion, reaching a maximum elevation of 1200 feet; another branch of the Carpathians in the west of the government ranges between 700 and 900 feet at its highest points. Both are deeply grooved in some places, and the crags give a hilly aspect to the districts where they occur. The remainder of the government, which is quite flat, with an imperceptible slope towards the marshes of Pinsk, is known as the Polyesie (see MINSK). It is covered by impassable marshes (sometimes as much as 400 square miles in extent), sparsely interspersed with forests and traversed by languid streams, with low, almost inaccessible banks, here and there diversified by sandy dunes. The drainage of the Polyesie is, however, being vigorously carried on, and large tracts of meadow land have already been reclaimed by extensive operations recently undertaken by Government. Among the marshes are many small lakes. Volhynia is copiously watered by a number of comparatively unimportant rivers which rise in the Avratynsk Hills and flow northwards towards the Dnieper; the Pripet with the Turia, the Styr, the Goryñ, the Slutch, and other smaller tributaries of the Dnieper are navigable by small boats, and considerable quantities of timber and firewood are floated. By the western Bug, which separates Volhynia from Poland, timber is floated and corn and various goods shipped to Prussia.

The geological formation of Volhynia is very simple. The Avratynsk Hills, consisting of granite and various crystalline rocks, are covered with the Chalk, above which in turn are Tertiary sandstones, sands, and clays containing lignite. The whole is covered by Glacial deposits and Lacustrine clays, reaching a great thickness in the north. Kaolin, pottery clay, and iron ore are the chief mineral products; amber also is occasionally found in the Tertiary sands. The climate of Volhynia, notwithstanding the influence of its marshes, is much milder than that of central Russia within the same latitudes. The vegetation on the southern slopes of the Avratynsk Hills begins to show something of a West-European character; oaks, maples, and limes prevail, while on the northern slope there are immense forests of Scotch fir. The forests cover more than one-third of the entire area, and it is reckoned that 2,500,000 acres yield timber for building purposes.

The population of Volhynia in 1884 was 2,096,475, of whom nearly four-fifths were Little Russians (from 70 to 91 per cent. in various districts); there were 30,000 White Russians and some 10,000 Great Russians. Next in importance to the Russians come the Jews, who numbered about 12 per cent. of the population. The Poles are variously estimated at from 120,000 to 170,000 but are certainly under 7 per cent. of the total population. The Germans number about 30,000. Agriculture cannot be said to flourish except on the Avratynsk plateau and its slopes, but is still the chief occupation, and more than one-third of the area is under crops. The fertile soil of the south produces a surplusage of corn, which is either used in distilleries or exported; the average crops from 1883 to 1885 were 1,606,000 quarters of rye, 550,000 of wheat, 1,145,060 of oats, 394,000 of barley, and 1,032,000 of potatoes. Hay is exported, but cattle-breeding has been almost stationary since 1850. In 1883 there were 506,500 horses, 655,050 cattle, and 571,500 sheep. Wool is exported. Beet is largely grown for sugar (38,000 acres, producing 4,800,000 cwts., having been under this crop in 1885). The culture of tobacco is rapidly extending (7000 tobacco plantations yielding about 8000 cwts. of tobacco in 1885). In the Polyesie the principal occupations are connected with the export of timber and firewood, the preparation of pitch, tar, potash, and various wooden wares, and boat-building. The wild boar, bear, fox, and hare are hunted.

The manufacturers in 1884 yielded 18,884,000 roubles [$14,540,680] as against only 2,856,000 [$2,199,120] in 1860. The goods principally produced are sugar, spirits, woollen cloth, paper, china, and metal wares. Wool, corn, hides, and tallow are partly manufactured within the government, and partly exported to Riga and Poland. Volhynia is traversed by a railway from Kieff *via* Berditcheff to Brest Litovsk, with branches to Lublin and to Lemberg. The traffic by this line is considerable, and the Radziviloff custom house, on the Austrian frontier, is one of the most important in Russia.

Volhynia is divided into twelve districts, the chief towns of which are ZHITOMIR (*q v.*), which had 54,830 inhabitants in 1884, Dubno (7255), Kovel (13,980), Kremenets (10,560), Lutsk (13,770), Novgrad Volhynskiy (13,590), Ostrog (16,520), Ovrutch (6480), Radziviloff (7350), Rovno (7300), Staro-Konstantinoff (17,980), and Zasłavl (10,120).

Volhynia has been inhabited by Slavonians from a remote antiquity. In Nestor's *Annals* its people are mentioned under the name of Dulebs, and later in the 12th century they were known as Velhynians and Buzhans (dwellers on the Bug). From the 9th century the towns of Volhynia—Vladimir, Ovrutch, Lutsk, and Dubno—were ruled by descendants of Rurik, and the land of Volhynia remained independent until the 14th century, when it fell under Lithuania. In 1659 it was annexed to Poland, and so remained until 1795, when it was taken possession of by Russia.

VOLNEY, CONSTANTIN FRANÇOIS CHASSEBŒUF, COMTE DE (1757–1820), was born at Craon, on February 3, 1757, of a good but not noble family, and educated first at the neighboring provincial towns of Ancenis and Angers, then at Paris. According to the common and curious habit of the time and country he was at first surnamed Boisgirais, but afterwards assumed the name of Volney. When he was about four and twenty he acquired some reputation by an essay on the chronology of Herodotus, and was introduced into literary and philosophical society. He then did what was at the time not common, common as it has become since. Having inherited a sum of money, he visited the East and spent some four years in Egypt and Syria, writing the history of his travels when he returned, and publishing it in 1787. He had not merely travelled but had learnt Arabic and had studied the politics as well as the topography of the countries he visited. Of the former study he gave evidence the year before the Revolution by some *Considerations* on the war between Russia and Turkey. He was a member both of the States-General and of the Constituante, and distinguished himself as an ardent reformer. In 1791 appeared the book *Les Ruines*, by which he is known to a great many people who have never read it. It is a kind of essay on the philosophy of history written from the *philosophe* point of view, and of course containing some direct and much oblique manifestation of *philosophe* antipathy to religion. It is probable, however, that those who, after the lapse of a century, read it under the impression of the strong denunciations of it by some orthodox writers of its own and immediately succeeding times will be not a little surprised. The book, of which the full title is *Les Ruines, ou Méditation sur les Révolutions des Empires*, purports to contain the discourses of a traveller among the ruins of Palmyra with a very 18th-century genius. Volney was a good deal more than a mere author. He tried to put his politico-economic theories into practice in Corsica, where in 1792 he bought an estate and made an attempt to cultivate colonial produce. He was thrown into prison during the Jacobin triumph, but escaped the guillotine. He was some time professor of history at the newly-founded École Normale,[1] lectured there, and published his lectures. Then he undertook a journey to the United States, the result of which took form in a book (chiefly geographical) published in 1803. Next year he republished and much enlarged his early essay on Herodotus. He was not a partisan of Napoleon, but, being a moderate man, a savant, and a Liberal, was impressed into service by the emperor, who made him a count and put him into the senate, of which he was one of the least servile members. The restoration in the same way recruited him against his will, and he became a peer of France. He was a member of the Institute and latterly of the Academy proper, and besides his historical, political, and (as the 18th century understood philosophy) philosophical studies, was a philologist of some power. He died at Paris on April 25, 1820, and his complete works appeared soon afterwards in eight volumes.

---

[1] [The École Normale was suppressed in 1795, which led to the American visit. The year before Volney dissuaded Napoleon from taking military service under a foreign government.—AM. ED.]

Volney has been called the last of the *philosophes*, and so, if date and eminence together be considered, he was. It may, as in many such cases, be doubted whether his identification with a powerful but one-sided movement was more of service than of disservice to him. No doubt it stimulated his work, but it also cramped and distorted it,—the curious and not wholly intelligible attitude of the whole school towards Christianity showing itself distinctly in him as a prejudicing and narrowing force. He was, however, an accurate observer, a thinker of acuteness and originality if not of great width or depth, and master of his pen in no ordinary degree. His style suffers from the general defects of 18th century French prose, in being thin, colorless, and devoid of flavor despite its clearness and brilliancy. But it serves him as a most excellent vehicle both of description and of argument.

VOLO, a town and seaport of Greece, on the east coast of Thessaly, at the head of the gulf to which it gives its name. Volo lies just below the mouth of the little river Orchestus, near the west foot of Mount Pelion, on the southern verge of an undulating and extremely fertile plain, which stretches thence northwards beyond Larissa, and which is skirted on the east by the chain above which tower Pelion, Ossa, and Olympus. The town which has a mixed population (1884) of 4000, comprises three distinct quarters: the kastro, enclosed by walls and inhabited chiefly by Turks; the scala, or port, centre of the trade and shipping; and the squalid Græco-Jewish suburb, which stretches from near the kastro to the coast. Volo, which is regularly visited by the Austrian, French and Greek steamers plying weekly between the Piræus and Constantinople, is the only outlet for the produce of northern Greece. The exports (tobacco, hides and skins, fruits, olive oil, raw silk and cocoons, etc.) were valued in 1886 at £31,000 [$150,660], while the imports (cereals, cotton goods, petroleum, sugar, hardware, etc.) amounted to £259,000 [$1,258,740].

The castle of Volo stands on or close to the site of Pagasæ, whence the gulf took the name of Sinus Pagasæus or Pagasicus, and which was one of the oldest places of which mention occurs in the legendary history of Greece. From this port the Argonautic expedition was said to have sailed, and it was already a flourishing place under the tyrant Jason, who from the neighboring Pheræ ruled over all Thessaly. Two miles farther south stand the ruins of Demetrias, founded (290 B.C.) by Demetrius Poliorcetes, and for some time a favorite residence of the Macedonian kings. On the opposite side of the little inlet, at the head of the gulf rises the hill of Episcopi, on which stood the ancient city of Iolcus. Here Dr. Lolling discovered in 1883 some underground sepulchral chambers resembling those of Mycenæ and Orchomenus.

VOLOGDA, a government of northeastern Russia, having Archangel on the N., Tobolsk on the E., Perm, Vyatka, Kostroma and Yarosłavl on the S., Novgorod and Olonetz on the W. This immense government, which comprises an area of 155,500 square miles, stretches in a northeasterly direction for 800 miles, from Novgorod to the Urals, including the broad depression drained by the Sukhona from the S. W. and the Vytchegda from the N. E., headwaters of the Dwina. From the basin of the Volga it is separated by a flat, swampy and wooded swelling, where the heads of tributaries belonging to both Arctic and Caspian drainage-areas are closely intermingled. The eastern boundary of Vologda follows the main waterparting of the Urals, which has but few points over 3000 feet; wide *parmas*, or woody plateaus, fill up the space between the main Urals and the southern spurs of the Timansk Mountains, in the upper basin of the Petchora, and it is above the parmas—especially over those which are nearest to the Urals proper—that the highest summits of the Urals rise in the form of dome-shaped mountains (Tellpöss, 5540 feet above sea-level; Hoste-piär, 4955 feet; Idjed-kashem, 4225 feet). The Timansk Mountains are a swampy plateau, where the rivers flowing either to the Dwina or to the Petchora take their rise in common marshes; so that on the Myłva portage boats have to be dragged only a distance of three miles through marshy forests to be transported from one system to the other.

Permian sandstones and cupriferous slates cover most of the territory; only a few patches of Jurassic clays overlie them: while in the east, in the Ural *parmas*, coal-bearing Carboniferous, Devonian, and Silurian slates and limestones appear, covering the crystalline slates of the main ridge. Vast layers of boulder clay and Lacustrine deposits cover the whole. Rock-salt and salt springs, iron ore, millstones, and grindstones are the chief mineral products; but mining is in its infancy.

Vologda is profusely watered; as many as 4800 rivers and streams have been counted on its maps. The Sukhona, which rises in the southwest and flows northeast past Vologda, Totma, and Velikiy Ustyug, is navigable for 375 miles. After its junction with the Yug (390 miles long), which comes from the south, it becomes the Dwina, which flows northwest, and receives the Vytchegda, another great river, 740 miles long and navigable for 570 miles, which, however, waters a nearly uninhabited region. The Luza, a tributary of the Yug, is also navigated for more than 250 miles. The Petchora, which flows through eastern Vologda, is an artery for the export of corn and the import of fish in the Petchora region, otherwise difficult of access. The Pinega, the Mezeñ, and the Vaga, all belonging to the Arctic basin, rise in northern Vologda. In the southwest the Sukhona is connected by means of Lake Kubenskoye and the canal of Alexander of Würtemberg with the upper Volga. Numberless smaller lakes occur, and marshes cover a considerable part of the surface.

The climate is severe, the average yearly temperature being 36° F. at Vologda (Jan., 10.7°; July, 63.5°) and 32.5° at Ust-Sysolsk (Jan., 4.8°; July, 61.7°).

The flora and the physical aspects present a great variety of characters as the traveller moves northeast down the Sukhona and up the Vytchegda, towards the *parmas* of the Petchora. In the southwest the forests are cleared, and the dry slopes of the hills are covered with fields and meadows; the population is relatively dense, and nearly one-quarter of the area is under crops. There is a surplus of grain, which is used for distilleries; and apples are extensively cultivated. The flora is middle-Russian. Farther to the northeast the climate grows more severe; but still, until the Dwina is reached, corn succeeds well, and there is no lack of excellent meadows on the river-terraces. Flax is cultivated for export; but only 4 per cent. of the area is tilled, the remainder being covered with thick fir forests, with occasional woods of deciduous trees (birch, aspen, elder). At about the 46th degree of east longitude the larch appears and soon supersedes the fir. Several plants unknown in western Russia make their appearance (*Silene tartarica, Anthyllus vulneraria, Euphorbia palustris, Filago arvensis, Lycopodium complanatum, Sanguisorba officinalis*). The *Veratrum* is especially characteristic: it sometimes encroaches on the meadows to such an extent as to compel their abandonment. The region of the upper Mezeñ (the Udora) again has a distinctive character. The winter is so protracted, and the snowfall so copious, that the Zyrians are sometimes compelled to clear away the snow from their barley-fields. But the summer is so hot (a mean of 54° for the three summer months) that barley ripens within forty days after being sown. The Timansk plateaus are a marked boundary for the middle-Russian flora. Those to the east of them are uninhabitable; even on the banks of the rivers the climate is so severe, especially on account of the icy northern winds, that rye and barley are mostly grown only in orchards. The whole is covered with quite impenetrable forests, growing on a soil permeated with water. Mosquitoes swarm in the forests; birds are rare. The Siberian cedar begins, and the lime-tree disappears. Fir, cedar, pine, and larch chiefly compose the forests, with birch and aspen on their outskirts. Hunting is the chief occupation of the Zyrian inhabitants.

The population (1,172,250 in 1883 as against 960,850 in 1861), consists chiefly of Great Russians (88 per cent.), and Zyrians (12 per cent.; only 7 per cent. according to Rittich). The Zyrians—a Finnish stem akin to the Permians—constitute the bulk of the population on the Ural slopes. They formerly inhabited the Kama and Vyatka basins, and call themselves Komi-yurt, or Komi-yas, and in the 14th century the Russians hardly distinguished them from the Permians; but they were compelled to migrate northwards into the basins of the Dwina and Petchora, and even across the Urals, by the religious fanaticism of the earlier Christian missionaries. A portion of them now live in Archangel (about 15,000), and their aggregate numbers are estimated at from 100,000 to 120,000, but the figures are very uncertain, as they are often hardly distinguishable from the Russians, whose religion and habits they have assumed. They differ widely from the western Finns in having dark eyes and hair; their honesty is proverbial, as also is their industry. They grow corn amidst the forests, after having patiently cleared them, and rear cattle, but are pre-eminently hunters. Their "artels," guided by a primitive compass, penetrate hundreds of miles into the virgin forests, and bring in vast quantities of squirrel furs and feathered game; they fell timber for export, and gather cedar-nuts, but in doing so are rapidly destroying the cedar-tree.

The chief occupation of the Russians is agriculture, and the average crops of 1883 to 1885 were rye, 785,000 quarters; barley, 926,000; oats, 925,000; other grains, 197,000; and potatoes, 107,000 quarters. In 1883 they had 229,500 horses, 520,200 cattle, and 392,900 sheep. They also fell timber, prepare tar, pitch, and potash, and manufacture wooden utensils. In the southwest they pursue a variety of domestic trades (spinning, weaving, sewing of plain cloth, etc.). The manufacturing industry is represented by a few iron-works, distilleries, paper-mills, and a variety of small manufactures; their aggregate production was only £274,500 [$1,334,070.00] in 1884. Salt was raised in 1881–84 to the average amount of 65,000 cwts. Flax, linen cloth, linseed, butter, tar, pitch, timber, and furs are the main items of export, the chief centres for trade being Vologda, Verkhovajsk, and Ustyug.

Vologda is divided into ten districts, the chief towns (with populations in 1881) being VOLOGDA (17,025), Gryazovets (2225), Kadnikoff (1520), Nikolsk (1880), Solvytchegodsk (1320), Totma (3380), Ustyug Velikiy (7980), Ust-Sysolsk (4100), Velsk (1410), and Yarensk (1250). (P. A. K.)

VOLOGDA, capital of the above government, is situated in its southwestern corner, 302 miles to the northeast of Moscow, with which it is connected by rail *via* Yaroslavl. It is an old town, having many relics of the past in its churches, including one which dates from the 12th century, and the cathedral founded in 1565. The educational institutions are in a better state than in many other provincial towns. Vologda, though a place of only 17,025 inhabitants in 1881, is a considerable commercial centre—flax, linseed, oats, hemp, butter, and eggs being bought to a large amount in the neighboring districts and in Vyatka, and exported both to St. Petersburg and Archangel.

Vologda existed as a place of commerce as early as the 12th century. It was a colony of Novgorod, and, owing to its advantageous position and the enterprise of the Novgorod merchants, it grew to be a populous city. It carried on a brisk trade in flax, tallow, and furs, which were sent in from Ustyug Velikiy,—another important colony of Novgorod; while the Byelo-ozero merchants brought to Vologda and Ustyug corn, leather, and various manufactured goods to be bartered against furs, or to be shipped to Klołmogory, at the mouth of the Dwina. In 1273 it was plundered by the prince of Tver in alliance with the Tartars, but soon recovered. Moscow disputed its possession with Novgorod until the 15th century; the Moscow princes intrigued to find support amidst the poorer inhabitants against the richer Novgorod merchants, and four successive times Vologda had to fight against its metropolis. It was definitely annexed to Moscow in 1447. When Archangel was founded, and opened for foreign trade in 1553, Vologda became the chief depôt for goods exported through that channel. They were brought on sledges from Moscow, Yarołsavl, and Kostroma; and special *yams*, or post stations, were maintained to connect Vologda with Moscow. Many foreigners lived at Vologda; Fletcher, the British envoy, stayed there, and the first Russian envoy to Britain came originally from Vologda. Polish bands plundered it in 1613, and the plague of 1648 devastated it; but it maintained its commercial importance until the foundation of St. Petersburg, when Russian foreign trade took another channel.

VOLSCI. See ITALY, vol. xiii. p. 454, and ROME, vol. xx. p. 753, 758–9.

VOLSK, or VOLJSK, a district town of Russia, in the government of Saratoff, and 90 miles to the northeast of that town, on the right bank of the Volga, was a century ago but a small village (Małykovo); recently, however, it has grown to be one of the important towns on the lower Volga, and its population has rapidly increased from 23,500 in 1860 to 36,315 in 1885. It is built in a narrow valley between chalk cliffs, and has a large cathedral and a market; it is surrounded by gardens, the produce of which is exported to Nijni-Novgorod—gardening being also a distinctive feature of the wealthy and populous neighboring villages.

VOLTA, ALESSANDRO (1745–1827), was born at Como on February 18th, 1745. In 1774 he was appointed professor of physics in the gymnasium of Como, and in 1777 he left his native town for the first time to travel through Switzerland, where he formed an intimate friendship with De Saussure. In 1779 a chair of physics was founded in Pavia, and Volta was chosen to occupy it. In 1782 he undertook a journey through France, Germany, Holland, and England, and became acquainted with nearly all the scientific celebrities of that day. In 1791 he received the Copley medal of the Royal Society. In 1801 Napoleon called him to Paris, to show his experiments on contact electricity, and a medal was struck in his honor. He was made a senator of the kingdom of Lombardy. In 1815 the emperor of Austria made him director of the philosophical faculty of Padua. In 1819 he retired, and settled down again in his native town. He died on March 5, 1827.

The first published paper of Volta (*De Vi Attractiva Ignis Electrici*) dates from 1769; it contains no new facts, but deserves our attention as showing us the knowledge with which Volta set out on his journey of discoveries, and the theoretical speculations which seem to have given him the first impulse to experimental work. Franklin, who was then justly considered the great authority on these matters, had endeavored to explain electrical phenomena by the mutual repulsion of the particles of an electrical substance and the attraction between that electrical substance and ordinary matter. Volta tried to simplify the theory by assuming an action only between the electrical substance and matter, and he tells us that he explained his views in a letter to the Abbé Nollet when he was nineteen years old. The way in which he endeavored to account for the phenomena of attraction and repulsion and the phenomena of the Leyden jar have no interest for us to-day, but that part of his paper in which he showed the application of his theory to the generation of electricity is of historical importance, for in it we can trace the germ of many future discoveries. He imagines all bodies in the natural state to contain electricity in such proportion that they are in electrical equilibrium. He believes that his experimental results obtained by rubbing metals with each other show this. But when bodies are brought into close contact, as, for instance, in friction, adopting the views of Boscovich, according to which attraction and repulsion alternate at small distances, he considers that the attractions of electricity and matter may alter and a new electrical equilibrium will establish itself. He asks the question whether during the progress of chemical action, such as solution, mixture of fluids, combustion, in which the particles of matter change their position, there is no disturbance of electrical equilibrium. He expresses his conviction that this is the case, and explains the experimental difficulties which prevent a proof, but expresses a hope that he will succeed in obtaining signs of electrical action during chemical operations. He shows how atmospheric electricity might be accounted for in accordance with these views.

The principal point of interest in his second paper (*Novus ac Simplicissimus Electricorum Tentaminum Apparatus*) is the attempt to explain electrical insulation by a repulsion between the insulating matter and electricity. The influence of Boscovich in this attempt to explain everything by forces and centres of force is here apparent. Theory thus seems to have given Volta the first impulse to his electrical inquiries; but as he went on with his experimental work the firm establishment of facts took the first place in his mind, and after the first two papers we find hardly anything speculative in his writings.

On June 10, 1775, Volta announced the construction of the electrophorus in a letter to Priestley, asking him, as the historian of electricity, how far the discovery was new. The remainder of the year seems to have been taken up with improvements in the mechanical construction of the apparatus. A letter to De Saussure in 1778 treats of the electrostatic capacity of conductors. Although we now know that Cavendish had treated the same subject in a much more complete way, the researches of Cavendish have only recently been published, and Volta's experiments are a great advance on anything that had been published at the time. The construction of the condenser, and its applications to the study of electrical phenomena, were first published in the *Philosophical Transactions* (1782). By means of the delicate apparatus at his disposal he returned to the ideas announced in his first paper, and tried to discover signs of electricity during the processes of evaporation and ebullition, and during changes of temperature; after repeated failure he at last believed himself to have succeeded in obtaining electrical effects during the evaporation of water. The first successful experiments were made in Paris, in the presence of Lavoisier and Laplace. We know now that evaporation by itself does not cause a difference in electric potential, and that Volta's effect was due to friction of the vapor generated against the sides of the vessel; but this has only been established quite recently.

The results on electrical effects due to evaporation led Volta to the closer investigation of the phenomena of atmospheric electricity, a subject which seems always to have had a special attraction for him. Between 1788 and 1790 he wrote nine letters on *Meteorologia Elettrica* addressed to Lichtenberg. The first two letters treat of electrical measurements. For the pith ball electroscope he substitutes the straw electrometer, in which the angle of divergence of two electrified straws is measured. Different electrometers of various sensitiveness are carefully graduated and compared with each other. Nor is this all: Volta has never as yet received the credit of having constructed the first absolute electrometer, and for having compared his other instruments with it, so that it would be possible now to refer all his measurements to absolute units. His electrometer consisted of a balance, one pane of which was a flat round disk. Below this disk was placed a larger parallel plate, conducted away to earth, and stops were arranged so that the disk could not approach the plate nearer than 2 inches. In the unelectrified state the balance was in a state of equilibrium. When the disk is electrified it is attracted towards the plate but kept at its proper distance by the stops; weights are then added in the other plate of the balance until the disk is torn away from the stops.

The remaining letters addresssd to Lichtenberg contain observations on atmospheric electricity and on the action of points and flames in discharging electricity. The reader cannot help feeling how very little more we now know about these matters than Volta did.

It was probably in 1790 that Galvani first made the observations which have rendered him celebrated. He was struck by the muscular contractions of a frog which had recently been killed and skinned, and was lying on a table near an electrical machine, which was accidentally set to work. In order to see whether he could obtain similar contraction from atmospheric electricity, he suspended the thigh of a frog by means of a hook from an iron railing, and found the contraction whenever the muscle touched the railing. He tried to account for the observation by assuming that the nerves and muscles of the animal body formed a kind of Leyden jar, which was discharged whenever an external circuit brought them into electrical contact. Volta at first agreed to this explanation, but his own experiments soon led him to change his opinion. It is very instructive to read the various letters and essays in which Volta describes his observations and his reasoning which gradually led him up to the construction of the electrical pile. His whole experimental training as well as the speculations of his early youth seemed to force him on in the right path, and in this work, as indeed in his whole career, none of the discoveries seems due to chance. The muscle of the frog soon appeared to him to be nothing but a very delicate electrometer, and he made use of it as such. The conductors he divided into two classes. Conductors of the first kind, to which carbon and the metals belong, he showed to become electrified by contact, but in such a way that equilibrium is established in each circuit, so that no current of electricity can be produced by any arrangement containing conductors of this class only. Conductors of the second kind are what we should now call electrolytes. An electric current is produced whenever a circuit is arranged between two conductors of the first kind and one of the second kind. It is impossible here to enter into the history of this now celebrated contact theory, but, although opinions may differ on the interpretation of some of the experiments, there is not much in Volta's writings on this subject which could be called incorrect even at the present day. Volta's electric pile was first described in a letter to Sir J. Banks, then president of the Royal Society. The letter is dated March 20, 1800, and it was read before the Society on June 26 of the same year. The pile consisted of a number of disks of tin and an equal number of disks of silver or copper. The zinc and tin plates are in contact, and each pair is separated by some porous matter which is kept moist. He describes a number of experimental results obtained with this pile, and finally shows that all the effects produced are the same as those which can be obtained from electrical machines, and that therefore "galvanism" and "electricity" are identical. Volta lived to see the remarkable development of his science at the hands of Sir Humphry Davy, Oersted, and Ampère, but he was no mathematician, and the subject grew beyond his powers. He recognized this with that frank honesty which is apparent in all his writings, and during the last twenty-five years of his life he published nothing on electrical subjects.

A complete history of Volta's writings ought to take in much which must be omitted here. His investigations on gas analysis, and his very interesting paper on the expansion of gases by heat, deserve, however, to be mentioned. He showed the causes which had led different experimenters to such inconsistent results, and established independently what is now known as the law of Charles. (A. S.*)

VOLTAIRE, FRANÇOIS MARIE AROUET DE (1694–1778), whose real name was FRANÇOIS MARIE AROUET simply, was born on the 21st of November, 1694, at Paris, and was baptized the next day. His father was François Arouet, a notary; his mother was Marie Marguerite Daumart (sometimes, but less correctly, spelt D'Aumard, apparently because her family was noble). Both father and mother were of Poitevin extraction, but the Arouets had been for two generations established in Paris, the grandfather being a prosperous tradesman, and the father, as has been said, a still more prosperous notary. The Arouet family are heard of in Poitou as far back as the early 16th century, and appear to have always belonged to the yeoman-tradesman class. Their special home was the town of St. Loup. Voltaire was the fifth child of his parents—twin boys (of whom one survived), a girl, Marguerite Catherine, and another boy who died young, having preceded him. Not very much is known of the mother, who died when Voltaire himself was but seven years old. She seems, however, to have had delicate health, and she pretty certainly was the chief cause of Voltaire's early introduction to good society, the Abbé de Châteauneuf (his sponsor in more ways than one) having been her friend. The father appears to have been somewhat peremptory in temper, but neither inhospitable nor tyrannical. Marguerite Arouet, of whom her younger brother was very fond, married early; the elder brother Armand was a strong Jansenist, and there never was any kind of sympathy between him and François.

Voltaire appears to have received no very regular education till he was ten years old; but the Abbé de Châteauneuf instructed him pretty early in belles lettres and deism, and he showed when quite a child the unsurpassed faculty for facile verse-making which always distinguished him, and to which the literary tastes and models of the time lent themselves with especial readiness. But at the age just mentioned he was sent to the Collége Louis-le-Grand, which was under the management of the Jesuits. This was in 1704. He remained there till 1711. It was his whim, as part of his general liberalism, to depreciate the education he received; but it seems to have been a very sound and good education, which beyond all doubt formed the basis of his extraordinarily wide, though never extraordinarily accurate, collection of knowledge subsequently, and (a more important thing still) disciplined and exercised his literary faculty and judgment. Nor can there be much doubt that the great attention bestowed on acting—the Jesuits kept up the Renaissance practice of turning schools into theatres for the performance of plays both in Latin and in the vernacular—had much to do with Voltaire's lifelong devotion to the stage. It must have been in his very earliest school years that the celebrated presentation of him by his godfather to Ninon de Lenclos took place, for Ninon died in 1705. She left him two thousand livres "to buy books with." Voltaire's school experience appears to have been much more like that of English schoolboys than like the dreary imprisonment of which in later days Frenchmen have generally complained. He worked fairly, played fairly, lived comfortably, made good and lasting friends. Some curious traits are recorded of this life—one being that in the terrible famine year of Malplaquet a hundred francs [$19.30] a year were added to the usual boarding expenses, and yet the boys had to eat *pain bis*.

His troubles began when, in August, 1711, at the age of 17, he came home, and the usual battle began between a son who desired no profession but literature and a father who, in those days not quite unreasonably, refused to consider literature a profession at all. For a time Voltaire submitted, and read law at least nominally, doing quite other things besides or instead of that study. The Abbé de Châteauneuf died before his godson left school, but he had already introduced him to the famous coterie of the Temple, of which the grand prior Vendôme was the head, and the poets Chaulieu and La Fare the chief literary stars, and which chiefly existed for purposes of sometimes elegant and sometimes by no means elegant dissipation. It does not appear that Voltaire got into any great scrapes, and the anecdotes recorded of this wild oats time of his are harmless enough. But his father naturally prognosticated little good to him from such society, and tried to break him off from it, by sending him first to Caen and then in the suite of the Marquis de Châteauneuf, the Abbé's brother, to the Hague. Here, however, he got into what, in the paternal eyes at least, was a far worse scrape than staying out at night or wasting his substance on the purchase of coaches and horses. He met a certain Olympe Dunoyer ("Pimpette"), a girl apparently of respectable character and not bad connections, but a Protestant, penniless, and daughter of a literary lady whose literary reputation was not spotless. The mother discouraged the affair, and, though Voltaire, with an early display of his afterwards famous cunning, tried to avail himself of the mania for proselytizing which then distinguished France, his father would not hear of the match, and stopped the whole affair by procuring a *lettre de cachet*, which, however, he did not use. Voltaire, who had been sent home, submitted, and for a time pretended to work in a Parisian lawyer's office. But he again manifested a faculty for getting into trouble,—this time in the still more dangerous way of writing libellous poems,—so that his father was glad to send him to stay for nearly a year (1714–1715) with Louis de Caumartin, Marquis de St. Ange, in the country. Here he was still supposed to study law, but as usual really devoted himself in part to literary essays, in part to storing up that immense treasure of gossiping history which was afterwards one of his most unique possessions. Almost exactly at the time of the death of Louis XIV. he returned to Paris, to fall once more into literary and Templar society, and to make the tragedy of *Œdipe*, which he had already written, privately known. He was now introduced to a less questionable and even more distinguished coterie than Vendôme's, to the famous "court of Sceaux," the circle of the beautiful and ambitious Duchesse du Maine. It seems, though it is not certainly known, that Voltaire lent himself to the duchess's frantic hatred of the regent Orleans, and helped to compose lampoons on that prince. At any rate, in May, 1716, he was exiled, first to Tulle, then to Sully. He was allowed to return, but again fell under suspicion of having been concerned in the composition of two violent libels,—one in Latin and one in French,—called from their first words the *Puero Regnante*, and the *J'ai vu*, was inveigled by a spy named Beauregard into a real or burlesque confession, and on May 16, 1717, was arrested and sent to the Bastille. He remained there for eleven months, recast *Œdipe*, began the *Henriade*, and determined to alter his name. Ever after his exit from the Bastille in April, 1718, he was known as Arouet de Voltaire, or simply Voltaire, though legally he never abandoned his patronymic. The origin of the famous name has been much debated, and attempts have been made to show that it actually existed in the Daumart pedigree or in some territorial designation. The balance of opinion has, however, always inclined to the hypothesis of an anagram on the name "Arouet le jeune," or "Arouet l. j.," *u* being changed to *v* and *j* to *i* according to the ordinary rules of the game. If it be so, the much despised art of the anagrammatist has the triumph of producing one of the dozen or score most famous names in literary history.

A further "exile" at Châtenay and elsewhere succeeded the imprisonment, and though Voltaire was admitted to an audience by the regent and treated graciously it is clear that he was not trusted, and the inconveniences he had suffered for a time induced even his incorrigibly mischievous nature to keep quiet. *Œdipe* was acted at the Théâtre Français on 18th November of the year of release, and was very well received, a not dissimilar rivalry between parties to that which not long before had helped Addison's *Cato* assisting its success. It had a run of forty-five nights, was acted at court, and brought the author not a little money in profits and presents, besides a gold medal from the regent. Voltaire seems to have begun with these gains his long and (among authors) almost unique series of successful financial speculations. But adversity had by no means done with him. In the spring of next year the production of Lagrange-Chancel's libels, entitled the *Philippiques*, again brought suspicion on him. He was informally exiled, and spent much time with Marshal Villars, again increasing his store of "reminiscences." He returned to Paris in the winter, and his second play, *Artémire*, was produced in February, 1720. It was a failure, and though it was recast with some success Voltaire never published it as a whole, and used parts of it up in other work. He again spent much of his time with Villars, listening to the marshal's stories and making harmless love to the duchess. In December, 1721, his father died, leaving him property (rather more than four thousand livres a year), which was soon increased by a pension of half the amount from the regent. In return for this, or in hopes of more, he offered himself as a spy—or at any rate as a secret diplomatist—to Dubois. He had, however, an awkward brush with a fellow-servant in this honorable kind of work, for, meeting his old enemy Beauregard in one of the minister's rooms and making an offensive remark, he was waylaid by Beauregard some time after in a less privileged place and soundly beaten. This unpleasant proceeding was only a preliminary to Voltaire's second and most important experience of "Black Will with a cudgel," to use Rochester's phrase as to the proper mode of dealing with troublesome men of letters. His visiting espionage, as unkind critics put it—his secret diplomatic mission, as he would have liked to have it put himself—began in the summer of 1722, and he set out for it *en bonne fortune*,—in company, that is to say, with a certain Madame de Rupelmonde, to whom he as usual made love, though it may perhaps be platonic love only (for Voltaire was not fortunate in this way), taught deism, and served as an amusing travelling companion. He stayed at Cambray for some time, where European diplomatists were still in full session, journeyed to Brussels, where he met and quarrelled with Jean Baptiste Rousseau, went on to the Hague, and then returned. It does not seem that he did anything diplomatically important, but from that day to this French Governments have had an amiable weakness for paying the travelling expenses of men of letters who feel inclined to see the world. The *Henriade* had got on considerably during the journey, and according to his life-long habit, the poet, with the help of his friend Thiériot and others, had been "working the oracle" of puffery after a fashion not particularly creditable, but perhaps recommended by a knowledge of mankind. During the late autumn and winter of 1722–23, he abode chiefly in Paris, taking a kind of lodging in the town house of M. de Bernières, a nobleman of Rouen, and endeavoring to procure a "privilege" for his poem. In this he was disappointed, but he had the work printed at Rouen, nevertheless, and spent the summer of 1723 revising it. In November he caught smallpox and was very seriously ill, so that the book was not given to the world till the spring of 1724 (and then of course, as it had no privilege, appeared privately). Almost at the same time, March 4, his third tragedy, *Mariamne*, appeared, at first with great success, but before the curtain fell complete damnation fell on it. The regent had died shortly before, not to Voltaire's advantage; for though that rather hardly treated person had little reason to love the poet he had been a generous patron to him. Voltaire had made, however, a useful friend in another *grand seigneur*, as profligate and nearly as intelligent, the duke of Richelieu, and with him he passed 1724, and the next year chiefly, recasting *Mariamne* (which was now successful), writing the comedy of *L'Indiscret*, and courting the queen, the ministers, the favorites, and everybody who seemed worth courting. The end of 1725 brought a disastrous close to this period of his life. He was insulted in one way or another by the Chevalier de Rohan, replied with his usual sharpness of tongue, and shortly afterwards, when dining at the Hôtel Sully, was called out and bastinadoed by the chevalier's hirelings, Rohan himself looking on. Nobody would take his part, and at last he challenged Rohan, who accepted the challenge, but on the morning appointed for the duel Voltaire was arrested and sent for the second time to the Bastille. This was nearly three months after the outrage. Voltaire had been ostentatiously taking lessons in fencing meanwhile, and it requires some effort to sympathize with him in all the circumstances. He was only kept in confinement a fortnight, and was then packed off to England in accordance with his own request. In the then state of social matters in France this was probably the best end of the matter, and nobody comes out of it so badly as the duke of Sully, who, by the code of gentlemen of all ages, was clearly bound to take the part of the guest who had been trepanned from his own table, and did not take it. But here also Voltaire took the best means of putting himself in the wrong and his enemies in the right by cutting Maximilien de Béthune's name out of the *Henriade*.

No competent judges have ever mistaken the importance of Voltaire's visit to England, and the influence it exercised on his future career. In the first place, the ridiculous and discreditable incident of the beating had time to blow over; in the second (as a previous experience of J. B. Rousseau's, which a good man of business like Voltaire was not likely to forget, had shown), England was a very favorable place for Frenchmen of note to pick up guineas; in the third, and most important of all, his contact with a people then far more different in every conceivable way from their neighbors than any two peoples of Europe are different now, acted as a sovereign tonic and stimulant on his intellect and literary faculty. Before the English visit Voltaire had been an elegant trifler, an adept in the forms of literature popular in French society, a sort of superior Dorat or Boufflers of earlier growth. He returned from that visit one of the foremost literary men in Europe, with views, if not profound or accurate, yet wide and acute on all *les grands sujets*, and with a solid stock of money to make him independent of those great men of his own country who had taught him how dearly their patronage was to be purchased. The visit lasted about three years, from 1726 to 1729; and, as if to make the visitor's luck certain, George I. died and George II. succeeded soon after his arrival. The new king was not fond of "boetry," but Queen Caroline was, and the international jealousy (which, though there was no actual war, was never stronger than then) was pleased at the thought of welcoming a distinguished exile from French illiberality. The Walpoles, Bubb Dodington, Bolingbroke especially. Sir Everard Falkener, a merchant and a diplomatist, Young, Congreve, Sarah Marlborough, Pope, were among his English friends. He at least tried to appreciate Shakespeare, and at least attained to the length of now copying and now reviling him. He was much struck (and it would appear not unfrequently hoaxed) by English manners, was deeply penetrated by English toleration for personal freethought and eccentricity, and (though the amount is very variously stated) certainly gained some thousands of pounds from an authorized English edition of the *Henriade* dedicated to the queen. But he visited Paris now and then, without permission (at other times he obtained permission to go without visiting it), and his mind, like the mind of every exiled Frenchman, was always set thereon. He at last gained full license to return in the spring of 1729.

He was full of literary projects, and immediately after his return he is said to have increased his fortune immensely by a lucky lottery speculation. The *Henriade* was at last licensed in France; *Brutus*, a play which he had printed in England, was accepted for performance, but kept back for a time by the author; and he began the celebrated poem of the *Pucelle*, the amusement and the torment of great part of his life. But he had great difficulties with two of his chief works which were ready to appear, and did after a fashion appear in 1731,—to wit, *Charles XII.* and the *Lettres sur les Anglais*. With both he took all imaginable pains to avoid offending the censorship; for Voltaire had, more than any other man who ever lived, the ability and willingness to stoop to conquer. At the end of 1730 *Brutus* did actually get acted with not inconsiderable but gradually decreasing success. Then in the spring of the next year he went to Rouen to get *Charles XII.* surreptitiously printed, which he accomplished. In all this nomadic life of his, which had now reached more than "the middle of the way," he had never had a house of his own, nor had he now, though for a rather unusually long time he was half-guest half-boarder with the Comtesse de Fontaine-Martel. In 1732 another tragedy, *Ériphile*, appeared with the same kind of halting success which had distinguished the appearance of its elder sisters since *Œdipe*. But at last, on August 13, 1732, he produced *Zaïre*, the best (with *Mérope*) of all his plays, and one of the ten or twelve best plays of the whole French classical school. Its motive was borrowed to some extent from *Othello*, but that matters little. In the following winter the death of his hostess turned him out of a comfortable abode. He still, however, did not set up housekeeping, but took lodgings with an agent of his, one Demoulin, in an out-of-the-way part of Paris, and was, for some time at least, as much occupied with contracts, speculation, and all sorts of means of gaining money as with literature.

It was in the middle of this period, however, in 1733, that two important books, the *Lettres Philosophiques sur les Anglais* and the *Temple du Goût* appeared. Both were likely to make bad blood, for the latter was, under the mask of easy verse, a satire on contemporary French literature, especially on J. B. Rousseau, and the former was, in the guise of criticism or rather panegyric of English ways, an attack on everything established in the church and state of France. It was published with certain "remarks" on Pascal, more offensive to orthodoxy than itself, and no mercy was shown to it. The book was condemned (June 10, 1734), the copies seized and burnt, a warrant issued against the author, and his dwelling searched. He himself, as usual henceforward, took care to be out of the way of danger, and was safe in the independent duchy of Lorraine with Madame du Châtelet, not having taken, but very shortly about to take, up his abode with that "respectable Emily" at her famous chateau of Cirey.

If the English visit may be regarded as having finished Voltaire's education, the Cirey residence may be justly said to be the first stage of his literary manhood. He had written important and characteristic work before; but he had always been in a kind of literary *Wanderjahre.* He now obtained a settled home for many years, and, taught by his numerous brushes with the authorities, he began and successfully carried out that system of keeping out of personal harm's way, and of at once denying any awkward responsibility, which made him for nearly half a century at once the chief and the most prosperous of European heretics in regard to all established ideas. He was in no great or immediate danger on this particular occasion, especially as he was perfectly ready to deny his authorship, and he travelled about for some time, visiting the camp at Philippsburg, where some not very important fighting, notable only for being the last campaign of Eugene, was going on. It was not till the summer of 1734 that Cirey, a half-dismantled country house on the borders of Champagne and Lorraine, was fitted up with Voltaire's money and became the headquarters of himself, of his hostess, and now and then of her accommodating husband. Many pictures of the life here, some of them not a little malicious, survive. It was not entirely a bed of roses, for the "respectable Emily's" temper was violent, and after a time she sought lovers who were not so much *des cérébraux* as Voltaire. But it provided him with a safe and comfortable retreat and with something of the same kind of convenience for literary work which matrimony provides for more commonplace or more scrupulous men of letters. In March, 1735, the ban was formally taken off him, and he was at liberty to return to Paris, a liberty of which he availed himself but sparingly now and ever afterwards, finding himself better away from the capital. At Cirey he wrote indefatigably and did not neglect business. The principal literary results of his early years here were the play of *Alzire* (1736) and a long treatise on the Newtonian system which he and Madame du Châtelet—an expert mathematician—wrote together. But as usual Voltaire's extraordinary literary industry was rather shown in a vast amount of fugitive writings than in substantive works, though for the whole space of his Cirey residence he was engaged in writing, adding to, and altering the *Pucelle.* In the very first days of his sojourn he had thus written a pamphlet with the imposing title of "Treatise on Metaphysics." Of metaphysics proper Voltaire neither now nor at any other time understood anything, and the subject, like every other, merely served him as a pretext for laughing at religion with the usual reservation of a tolerably affirmative deism. In March, 1736, one of the least creditable events of his life, yet still not wholly discreditable, happened. An avowal of the *English Letters* was got out of him privately and then used publicly as an engine of extortion. In the same year he received his first letter from Frederick of Prussia, then crown prince only. He was soon again in trouble, this time for the poem of the *Mondain*, and he at once crossed the frontier and then made for Brussels. He spent about three months in the Low Countries, and in March, 1737, returned to Cirey, and continued writing, making experiments in physics (he had at this time a large laboratory), and busying himself not a little with iron-founding, the chief industry of the district. The best known accounts of Cirey life, those of Madame de Grafigny, date from the winter of 1738–39; they are, as has been said, somewhat spiteful but very amusing, depicting the constant quarrels between Madame du Châtelet and Voltaire, his intense suffering under criticism, his constant dread of the surreptitious publication of the *Pucelle* (which nevertheless he could not keep his hands from writing or his tongue from reciting to his visitors), and so forth. The chief and most galling of his critics at this time was the Abbé Desfontaines, and the chief of Desfontaines's attacks was entitled *La Voltairomanie*, in reply to a libel of Voltaire's called *Le Préservatif.* Both combatants had, according to the absurd habit of the time, to disown their works, Desfontaines's disavowal being formal and procured by the exertion of all Voltaire's own influence both at home and abroad. For he had as little notion of tolerance towards others as of dignity in himself. In April, 1739, a journey was made to Brussels, to Paris, and then again to Brussels, which was the headquarters for a considerable time owing to some law affairs of the Du Châtelets. Frederick, now king of Prussia, made not a few efforts to get Voltaire away from Madame du Châtelet, but unsuccessfully, and the king earned the lady's cordial hatred by persistently refusing or omitting to invite her. At last, in September, 1740, master and pupil met for the first time at Cleves, an interview followed three months later by a longer visit at Remusberg. Brussels was again the headquarters in 1741, by which time Voltaire had finished the best and the second or third best of his plays, *Mérope* and *Mahomet. Mahomet* was played first in the year and at the place just mentioned; it did not appear in Paris till August next year, and *Mérope* not till 1743. This last was and deserved to be the most successful of its author's whole theatre. It was in this same year that he received the singular diplomatic mission to Frederick which nobody seems to have taken seriously, and after his return the oscillation between Brussels, Cirey, and Paris was resumed, in a manner rather difficult to record in a short biography. During these years Voltaire's production of miscellanies was as constant as usual, but his time allotted to serious work was chiefly given to history and much of the *Essai sur les Mœurs* and the *Siècle de Louis XIV.* was now composed. He also returned, not too well-advisedly, to the business of courtiership, which he had given up since the death of the regent. He was much employed, owing to Richelieu's influence, in the fêtes of the dauphin's marriage, and was rewarded on New Year's day, 1745, by the appointment to the post of historiographer-royal, once jointly held by Racine and Boileau. The situation itself and its accompanying privileges were what Voltaire chiefly aimed at, but there was a salary of two thousand livres attached, and he had the year before come in for three times as much by the death of his brother. In the same year he wrote a poem on Fontenoy, he received medals from the pope, and dedicated *Mahomet* to him, and he wrote court *divertissements* and other things to admiration. But he was not a thoroughly skilful courtier, and one of the best known of Voltairiana is the contempt or at least silence with which Louis XV.—a sensualist but no fool—received the maladroit and almost insolent inquiry *Trajan est il content?* addressed in his hearing to Richelieu at the close of a piece in which the emperor had appeared with a transparent reference to the king. All this assentation had at least one effect. He who had been for years admittedly the first writer in France had been repeatedly passed over in elections to the Academy. He was at last elected in the spring of 1746, and received on May 9. Then the tide began to turn. His favor at court had naturally exasperated his enemies; it had not secured him any real friends, and even a gentlemanship of the chamber was no solid benefit, except from the money point of view. He did not indeed hold it very long, but was permitted to sell it for a large sum, retaining the rank and privileges. He had various proofs of the instability of his hold on the king during 1747 and in 1748. He once lay in hiding for two months at Sceaux, and afterwards for a time lived chiefly at Lunéville, where Madame du Châtelet had established herself at the court of King Stanislaus, where she carried on her flirtations with Saint Lambert, and where, in September, 1749, she died, not in, but about four days after, childbirth.

The death of Madame du Châtelet is another turning point in the history of Voltaire. He was now not a young man—indeed he was fifty-five—but he had nearly thirty years more to live, and he had learnt much during what may be called his Cirey cohabitation. On the one hand, he had discovered that it was undesirable that a man should not have a household; on the other, he had discovered that it was still more undesirable that a man should put himself under illegitimate petticoat government. For some time, however, after Madame du Châtelet's death he was in a state of pitiable unsettlement. At first, after removing his goods from Cirey, he hired the greater part of the Châtelet town house and then the whole. He had some idea of settling down in Paris, and might perhaps have done so if mischief had not been the very breath of his nostrils. He could not bring himself to testify in any open and dangerous manner for what he thought to be the truth; he could not bring himself to refrain from attacking, by every artifice and covert enginery, what he thought to be falsehood. He went on writing tales like *Zadig*. He engaged in a foolish and undignified struggle with Crébillon *père* (not *fils*), a dramatist who, in part of one play, *Rhadamiste et Zénobie*, has struck a note of tragedy in the grand Cornelian strain, which Voltaire could never hope to echo, and who, in most of his other efforts, was and is mainly futile. He used the most extraordinary efforts to make himself more popular than he was, but he could not help being uncomfortable in a city where the court all but threatened, and where the city did more than all but laugh.

All this time Frederick of Prussia had been continuing his invitations, and the "respectable Emily" was no longer in the way. It does not appear that, at any rate at first, Frederick made any real difficulty as to money. Indeed he behaved on the whole very generously. Voltaire left Paris on the 15th June, 1751, and reached Berlin on the 10th July.

This Berlin visit might itself be treated, without undue extension, at the length of the present article; but its circumstances may be presumed to be already more or less familiar to most English readers from the two great essays of Macaulay and Carlyle as well as from the *Frederick* of the latter. It is desirable, if not altogether necessary, to say that these two masters of English were not perhaps the best qualified to relate the story. Both were unjust to Voltaire, and Macaulay was unjust to Frederick as well. It is quite certain that at first the king behaved altogether like a king to his guest. He pressed him to remain; he gave him (the words are Voltaire's own) one of his orders, twenty thousand francs a year, and four thousand additional for his niece, Madame Denis, in case she would come and keep house for her uncle. But Voltaire's conduct was from the first Voltairian. He sent a letter, in which Madame Denis pleaded with him to return, to Frederick—an odd way of ingratiating his niece with that monarch. He insisted on the consent of his own king, which was given without delay and on very liberal terms,—Louis XV., if gossip is to be trusted, pointing out with considerable shrewdness that it was not his fault if Voltaire would put himself constantly in hot water, and still less his fault that there were so few men of letters in Prussia that it suited the king of Prussia to ask them to dinner, and so many in France that it was quite impossible for the king of France to do so. Frenchmen, always touchy on such a point, regarded Voltaire as something of a deserter; and it was not long before he bitterly repented his desertion, though his residence in Prussia actually lasted for nearly three years. It was quite impossible that Voltaire and Frederick should get on together for long. Voltaire was not humble enough to be a mere butt, as many of Frederick's led poets were; he was not enough of a gentleman to hold his own place with dignity and discretion; he was constantly jealous both of his equals in age and reputation, such as Maupertuis, and of his juniors and inferiors, such as Baculard D'Arnaud. He was greedy, restless, and in a way Bohemian. Frederick, though his love of teasing for teasing's sake has been exaggerated by Macaulay, was anything but amiable in disposition, was a martinet of the first water, had a sharp though one-sided idea of justice, and had not the slightest intention of allowing Voltaire to insult or to tyrannize over his other guests and servants. If he is to be blamed in this particular matter, the blame must be chiefly confined to his imprudence in inviting Voltaire at the beginning and to the brutality of his conduct at the end. Within Voltaire there was always a mischievous and ill-behaved child; and he was never more mischievous, more ill-behaved, and more childish than in these years. But, knowing as we do what he was, there is much excuse for him. He tried to get D'Arnaud exiled and succeeded. He got into a quite unnecessary quarrel with Lessing, the most distinguished, or at least the most gifted, German author of the day. He had not been in the country six months before he engaged in a discreditable, and in Prussia directly illegal, piece of financial gambling with Hirsch, the Dresden Jew. He had the extreme unwisdom and meanness to quarrel with this agent of his about money, and was at least accused of something like downright forgery—that is to say, of altering a paper signed by Hirsch after he had signed it. The king's very well justified disgust at this affair (which came to an open scandal before the tribunals) was so great that he was on the point of ordering Voltaire out of Prussia and Darget the secretary had no small trouble in arranging the affair (February, 1751). Then it was Voltaire's turn to be disgusted with an occupation he had undertaken himself—the occupation of "buck-washing" the king's French verses. However, he succeeded in finishing and printing the *Siècle de Louis XIV.*, while the *Dictionnaire Philosophique* is said to have been devised and begun at Potsdam. But Voltaire's restless temper was brewing up for another storm. In the early autumn of 1751 La Mettrie, one of the king's parasites, and a man of much more talent than is generally allowed, horrified Voltaire by telling him that the king had in conversation applied to him, Voltaire, a proverb about "sucking the orange and flinging away its skin;" and about the same time the dispute with Maupertuis, which had more than anything else to do with his exclusion from Prussia, came to a head. No one quite knows how it began, though it is probably enough to say that Maupertuis and Voltaire had been of old quasi-rivals in the favor of the "divine Émilie," that as president of the Berlin Academy Maupertuis was in a manner Voltaire's literary superior, that he was a man of rough and boorish manners, and that he is said at least to have refused his aid in the Hirsch affair. He also seems to have had something at least to do with a tedious and complicated squabble arising from the work of a certain La Beaumelle, a literary hack of the time, not without ability, who chose to visit Berlin and court Voltaire. The final rupture was provoked by Maupertuis himself, though indirectly, by a dispute into which he got with one König. The king took his president's part; Voltaire (unluckily for him, but with sufficient adroitness to make no open breach) took König's. But Maupertuis must needs write his *Letters*, and thereupon (1752) appeared one of Voltaire's most famous, though perhaps not one of his most read works, the *Diatribe du Docteur Akakia*. Even Voltaire did not venture to publish this lampoon on a great official of a prince so touchy as the king of Prussia without some permission, and if all tales are true he obtained this by another piece of something like forgery—getting the king to endorse a totally different pamphlet on its last leaf, and affixing that last leaf to *Akakia*. Of this Frederick was not aware; but he did get some wind of the *Diatribe* itself, sent for the author, heard it read to his own great amusement, and either actually burned the MS. or believed that it was burnt. In a few days printed copies appeared. Now Frederick did not like disobedience, but he still less liked being made a fool of, and he put Voltaire under arrest. But again the affair blew over, which is at least a proof that the king was not wanting in long-suffering. He believed that the edition of *Akakia* confiscated in Prussia was the only one. Alas! Voltaire, according to his usual fashion, had sent copies away; others had been printed abroad; and the thing was irrecoverable. Of course it could not be proved that he had ordered the printing, and all Frederick could do was to have the pamphlet burnt by the hangman. Things were now drawing to a crisis. One day Voltaire sent his orders, etc., back; the next Frederick returned them, but Voltaire had quite made up his mind to fly. A kind of reconciliation occurred in March, and after some days of good-fellowship Voltaire at last obtained the long-sought leave of absence and left Potsdam on the 26th of the month (1753). It was nearly three months afterwards that the famous, ludicrous, and brutal arrest was made at Frankfort, on the persons of himself and his niece, who had met him meanwhile. There was some faint excuse for Frederick's wrath. In the first place, after a plea of business in Paris, of the necessity of the waters of Plombières, and so forth, it was a little incongruous that the poet should linger at Leipsic. In the second place, in direct disregard of a promise given to Frederick, a supplement to *Akakia* appeared, more offensive than the main text, and was followed by a paper war of letters with Maupertuis. But the king cooked his spleen and bided his time. From Leipsic, after a month's stay, Voltaire moved to Gotha, and seemed once more in no hurry to go on, his excuse being the compilation of *Annals of the Empire*, asked of him by the duchess of Saxe-Weimar. Once more, on May 25, he moved on to Frankfort, and here the blow fell. Frankfort, nominally a free city, but with a Prussian resident who did very much what he pleased, was not like Gotha and Leipsic. An excuse was provided in the fact that the poet had a copy of some unpublished poems of Frederick's, and as soon as Voltaire arrived the thing was done, at first with courtesy enough. The resident, Freytag, was not a very wise person (though he probably did not, as Voltaire would have it, spell "poésie" "poéshie"); constant references to Frederick were necessary; and the affair was prolonged so that Madame Denis had time to join her uncle. At last Voltaire did the unwisest thing he could have done by trying to steal away. He was followed, arrested, his niece seized separately, and sent to join him in custody; and the two, with the secretary Collini, were kept close prisoners at an inn called the Goat. This situation lasted some time (a time, indeed, since the "œuvre de poéshie" was at once recovered, rather unintelligible except on the score of Freytag's folly), and was at last put an end to by the city authorities, who probably felt that they were not playing a very creditable part. Voltaire left Frankfort on July 7th, travelled safely to Mainz, and thence to Mannheim, Strasburg, and Colmar. The last-named place he reached (after a leisurely journey and many honors at the little courts just mentioned) at the beginning of October, and here he proposed to stay the winter, finish his *Annals of the Empire*, and look about him.

Voltaire's second stage was now over, and he was about to try what an Englishman would have tried long before—complete independence of hosts and patrons, mistresses and friends. Even now, however, in his sixtieth year, it required some more external pressure to induce him to take this apparently obvious step. He had been, in the first blush of his Frankfort disaster, refused or at least not granted, permission even to enter France proper,—a rebuff probably due in about equal parts to a wish not to displease or disoblige Frederick, and a wish to punish Voltaire himself for selecting Prussia as a home. At Colmar he was not safe, especially when in January, 1754, a pirated edition of the *Essai sur les Mœurs*, written long before, appeared. Permission to establish himself in France was now absolutely refused; and even Madame de Pompadour was powerless, if indeed she cared greatly to exert her power. Nor did an extremely offensive performance of Voltaire's—the solemn partaking of the eucharist at Colmar after due confession—at all mollify his enemies. His exclusion from France, however, was chiefly metaphorical, and really meant exclusion from Paris and its neighborhood. In the summer he went to Plombières, and after returning to Colmar for some time journeyed in the beginning of winter to Lyons, and after a month there went, as it may almost be said, "home"—to a home which he had never yet visited, but which was, with slight changes of actual domicile, but with no change of neighborhood, to shelter him for the rest of his life.

His first resting-place, Geneva, was reached in the middle of December; but Voltaire had no purpose of remaining in the city, and almost immediately bought a country house just outside the gates, to which he gave the name of Les Délices. This, the first house of his own which he can be said to have possessed, is still standing, though now absorbed in the suburbs. It was pretty, with fine views; but it had advantages of a non-æsthetic kind for its owner, of which he made no secret. He was here practically at the meeting-point of four distinct jurisdictions—Geneva, the canton Vaud, Sardinia, and France, while other cantons were within easy reach. Before finally settling in Ferney he bought other houses dotted about these territories, so as never to be without a refuge close at hand in case of sudden storms. At Les Délices he set up a considerable establishment, which his great wealth (obtained chiefly by speculation in the manner already more than once hinted at) made him able easily to afford. He kept open house for visitors; he had printers close at had in Geneva; he fitted up a private theatre in which he could enjoy what was perhaps the greatest pleasure of his whole life—acting in a play of his own, stage-managed by himself. His residence at Geneva brought him into correspondence (at first quite amicable) with the most famous of her citizens, J. J. Rousseau. His *Orphelin de la Chine*, performed at Paris in 1755, was very well received; and the earthquake at Lisbon, which appalled other people, gave Voltaire an excellent opportunity for ridiculing the beliefs of the orthodox, first in verse (1756) and later in the (from a literary point of view) unsurpassable tale of *Candide* (1759). All was, however, not yet quite smooth with him. Geneva had a law expressly forbidding theatrical performances in any circumstances whatever. Voltaire, as has been said, had infringed this law already as far as private performances went, and he had thought of building a regular theatre, not indeed at Geneva but at Lausanne. In July, 1755, a very polite and, as far as Voltaire was concerned, indirect resolution of the consistory declared that in consequence of these proceedings of the Sieur de Voltaire the pastors should notify their flocks to abstain, and that the chief syndic should be informed of the consistory's perfect confidence that the edicts would be carried out. Voltaire obeyed this hint as far as Les Délices was concerned, and consoled himself by having the performances in his Lausanne house. But he never was the man to take opposition to his wishes either quietly or without retaliation. He undoubtedly instigated D'Alembert to include a censure of the prohibition in his *Encyclopédie* article on "Geneva," a proceeding which provoked Rousseau's celebrated *Lettre à D'Alembert sur les Spectacles*. As for himself, even still restless, he looked about for a place where he could combine the social liberty of France with the political liberty of Geneva, and he found one. At the end of 1758 he bought the considerable property of Ferney, on the shore of the lake, about four miles from Geneva and on French soil. At Les Délices (which he sold in

1765) he had become a householder on no small scale; at Ferney (which he increased by other purchases and leases) he became a complete country gentleman. He set about establishing himself handsomely in his new abode, and though he did not absolutely abandon his other houses he was henceforward known to all Europe as squire of Ferney, hardly less than as author of the *Henriade* and the *Pucelle*, of *Charles XII.* and *Akakia.*

From this time forward many of the most celebrated men of Europe visited him there, and large parts of his usual biographies are composed of extracts from their accounts of Ferney. His new occupations by no means quenched his literary activity, but on the contrary stimulated it. He did not make himself a slave to his visitors, but appeared only occasionally and reserved much time for work and for his immense correspondence, which had for a long time once more included Frederick, the two getting on very well when they were not in contact. Above all, he now, being comparatively secure in position, engaged much more strongly in public controversies, and, without wholly abandoning, resorted less to, his old labyrinthine tricks of disavowal, garbled publication, and private libel. The suppression of the *Encyclopédie*, to which he had been a considerable contributor, and whose conductors were his intimate friends, drew from him a shower of lampoons directed now at "l'infâme" (see *infra*) generally, now at literary victims, such as Le Franc de Pompignan (who had written one piece of verse so much better than anything serious of Voltaire's that he could not be forgiven), or Palissot (who had boldly gibbeted most of the *philosophes* in his play of that name, but had not included Voltaire), now at Fréron, an excellent critic and a dangerous writer, who had attacked Voltaire from the conservative side, and at whom the patriarch of Ferney, as he now began to be called, levelled in return the very inferior farce-lampoon of *L'Écossaise*, of the first night of which Fréron himself did an admirably humorous criticism.

How he built a church and got into trouble in so doing at Ferney, how he put "Deo erexit Voltaire" on it (1760–61) and obtained a relic from the pope for his new building, how he entertained a grand-niece of Corneille, and for her benefit wrote his well-known "commentary" on that poet, are matters of interest, but to be passed over briefly. Here, too, he began that series of interferences on behalf of the oppressed and the ill-treated which, whatever mixture of motives may have prompted it, is certainly an honor to his memory. Volumes and almost libraries have been written on the Calas affair, and it is impossible here to give any account of it or of the only less famous cases of Sirven (very similar to that of Calas, though no life was actually lost), Espinasse (who had been sentenced to the galleys for harboring a Protestant minister), Lally (the son of the unjustly treated but not blameless Irish-French commander in India), D'Étalonde (the companion of La Barre), Montbailli, and others.

In 1768 he entered, it would seem out of pure wantonness, into an indecent controversy with the bishop of the diocese (who, like an honest man, was not particularly well satisfied with his occasional conformity); he had differences with the superior landlord of part of his estate, the president De Brosses; and he engaged in a long and tedious return match with the republic of Geneva, in which the scoring was alternate and rather bewildering, Geneva playing at one time an insult to Voltaire's friend and patron Catherine of Russia, and Voltaire replying at another by setting up a rival colony of watchmakers at Ferney. The match went on the whole in favor of Voltaire, for during its course a theatre was authorized in the city and he himself, a kind of exile from it, was applied to to mediate between different classes of the community. But the general events of this Ferney life are somewhat of that happy kind which are no events—the distractions and employments of a man who has nothing serious to occupy himself about.

In this way things went on for many years, and Voltaire, who had been an old man when he established himself at Ferney, became a very old one almost without noticing it. The death of Louis XV. and the accession of Louis XVI. excited even in his aged breast the hope of re-entering Paris, but he did not at once receive any encouragement, despite the reforming ministry of Turgot. A much more solid gain to his happiness was the adoption, or practical adoption, in 1776 of Reine Philiberte de Varicourt, a young girl of noble but poor family, whom Voltaire rescued from the convent, installed in his house as an adopted daughter, and married to the Marquis de Villette. Her pet name was "Belle et Bonne," and nobody had more to do with the happiness of the last years of the "patriarch" than she had. It is doubtful whether his last and fatal visit to Paris was due to his own wish or to the instigation of his niece, Madame Denis; but it is fair to say that this lady—a woman of disagreeable temper, especially to her inferiors—appears to have been rather hardly treated by Voltaire's earlier, and sometimes by his later, biographers. The suggestion which has been made that the success of Beaumarchais piqued him has nothing impossible in it. At any rate he had, at the end of 1777 and the beginning of 1778, been carefully finishing a new tragedy—*Irène*—for production in the capital; he started on the 5th of February, and five days later arrived at the city which he had not seen for eight and twenty years.

Abundant as is the information respecting the whole, or almost the whole, of his life, it is nowhere more abundant than in respect to these last months. He was received with immense rejoicings, not indeed directly by the court, but by the Academy, by society, and by all the more important foreign visitors. About a fortnight after his arrival age and fatigue made him seriously ill, and a confessor was sent for. But he recovered, scoffed at himself as usual, and prepared more eagerly than ever for the first performance of *Irène*, on March 16. At the end of the month he was able to go out and attend a performance of it, which has often been described, and was a kind of apotheosis. He was crowned with laurel in his box, amid the plaudits of the audience, and did not for the moment seem to be the worse for it, enjoying several other triumphs, during one of which he had, in full Academic *séance*, to embrace Franklin after the French manner. He even began or proceeded with another tragedy,—*Agathocle*,—and attended several Academic meetings. But such proceedings in the case of a man of eighty-four were impossible. To keep himself up he exceeded even his usual excess in coffee, and about the middle of May he became very ill. For about a fortnight he was alternately better and worse; but on May 30 the priests were once more sent for,—to wit, his nephew the Abbé Mignot, the Abbé Gaultier, who had officiated on the former occasion, and the parish priest, the curé of St. Sulpice. He was, however, in a state of half insensibility, and petulantly motioned them away. The legends set afloat about his dying in a state of terror and despair are certainly false; but it must be regarded as singular and unfortunate that he who had more than once gone out of his way to conform ostentatiously and with his tongue in his cheek should have neglected or missed this last opportunity. The result was a difficulty as to burial which was compromised by hurried interment at the abbey of Scellières in Champagne, anticipating the interdict of the bishop of the diocese by an hour or two. On July 10, 1791, the body was transferred to the Pantheon, but it was not to rest there, and during the Hundred Days it was once more, it is said, disentombed, and stowed away in a piece of waste ground. His heart, taken from the body when it was embalmed, and given to Madame Denis and by her to Madame de Villette, was preserved in a silver case, and when it was proposed (in 1864) to restore it to the other remains the sarcophagus at Sainte Geneviève (the Pantheon) was opened and found to be empty.

In person Voltaire was not engaging, even as a young man. His extraordinary thinness is commemorated, among other things, by the very poor but well-known epigram attributed to Young, and identifying him at once with "Satan, Death, and Sin." In old age he was a mere skeleton, with a long nose and eyes of preternatural brilliancy peering out of his wig. He never seems to have been addicted to any manly sport, and took little exercise. He was sober enough (for his day and society) in eating and drinking generally; but drank coffee, as his contemporary, counterpart, and enemy, Johnson, drank tea, in a hardened and inveterate manner. It may be presumed with some certainty that his attentions to women were for the most part platonic; indeed, both on the good and the bad side of him, he was all brain. He appears to have had no great sense of natural beauty, in which point he resembled his generation (though one remarkable story is told of his being deeply affected by Alpine scenery); and, except in his passion for the stage, he does not seem to have cared much for any of the arts. Conversation and literature were, again as in Johnson's case, the sole gods of his idolatry. As for his moral character, the wholly intellectual cast of mind just referred to makes it difficult to judge that. His beliefs or absence of beliefs emancipated him from conventional scruples; and it must be admitted that he is not a good subject for those who maintain that a nice morality may exist independently of religion. He was good-natured when not crossed, generous to dependants who made themselves useful to him, and indefatigable in defending the cause of those who were oppressed by the systems with which he was at war. But he was inordinately vain, and totally unscrupulous in gaining money, in attacking an enemy, or in protecting himself when he was threatened with danger. In these three cases he stuck at no lie, found no weapons too foul to use, and regarded no gain as too dirty to pouch. His peculiar fashion of attacking the popular beliefs of his time has also failed to secure the approval of some who have very little sympathy with those beliefs, of not a few even who go so far as to approve of ridicule and indeed of mere ribaldry being used to wean those who hold things sacred from their belief in them. The only excuse made for the alternate cringing and insult, the alternate abuse and lying, which marked his course, in this matter, has been the very weak plea that a man cannot fight with a system,—a plea which is sufficiently answered by the retort that a great many men have so fought and have won. But this comes so closely to the discussion of Voltaire's works and intellectual character that it may be dismissed for the present with only one more remark, by no means new, but it would seem constantly requiring repetition. Voltaire's works, and especially his private letters, constantly contain the word "l'infâme" and the expression in full or abbreviated "écrasez l'infâme." This has been misunderstood in many ways,—the mistake going so far as in some cases to suppose that Voltaire meant Christ by this opprobrious expression. No careful and competent student of his works, whatever that student's sympathies, has ever failed to correct this gross misapprehension. "L'infâme" is not God, it is not Christ; it is not Christianity; it is not even Catholicism. Its briefest equivalent may be given as "persecuting and priviledged orthodoxy" in general, and, more particularly, it is the particular system which Voltaire saw around him, of which he had felt the effects in his own exiles and the confiscations of his books, and of which he saw the still worse effects in the hideous sufferings of Calas and La Barre, and in the less hideous but still severe miseries of persons perfectly guiltless, even according to their tormentors, such as the families of Calas and Sirven.

Vast and various as the work of Voltaire is, no article such as the present could be even approximately complete without some attempt to give an outline of its general contents and characteristics, for its vastness and variety are of the essence of its writer's peculiar quality. The divisions of it have long been recognized, and may be treated in order.

The first of these divisions in order, not the least in bulk, and, though not the first in merit, inferior to none in the amount of congenial labor spent on it, is the *theatre* of Voltaire. Between fifty and sixty different pieces (including a few which exist only in fragments or sketches) are included in his writings, and they cover the entire stretch of his literary life. It is at first sight remarkable that Voltaire, whose comic power was undoubtedly far in excess of his tragic, should have written many tragedies of no small excellence in their way but only one fair second-class comedy, *Nanine*. His other efforts in this latter direction are quite inferior, being either slight and almost insignificant in scope, or, as in the case of the somewhat famous *Écossaise*, deriving all their interest from being personal libels. His tragedies, on the other hand, though they can never fully satisfy those who have been accustomed to the stronger meat of romantic drama, are works of extraordinary merit in their own way. Although Voltaire had neither the perfect versification of Racine nor the noble poetry of Corneille, he surpassed the latter certainly, and the former in the opinion of some not incompetent judges, in playing the difficult and artificial game of the Franch tragedy. *Zaïre*, among those where love is admitted as a principal motive, and *Mérope*, among those where this motive is excluded and kept in subordination, yield to no plays of their class in such sustaining of interest as is possible on the model, in adaptation of that model to stage effect, and in uniform, if never very transporting or extraordinary, literary merit. Voltaire was an enthusiastic lover of the stage; he was intimately acquainted with its laws; he knew that the public opinion of his time reserved its highest prizes for a capable and successful dramatist; and he was determined to win those prizes. He therefore set all his wonderful cleverness to the task, going so far as to adopt a little even of that romantic disobedience to the strict classical theory which he condemned, and no doubt sincerely, in Shakespeare. The consequence is that his work in its kind is unlikely ever to be surpassed.

It is very different with his *poems* proper, of which there are two long ones, the *Henriade* and the *Pucelle*, besides smaller pieces, of which it is enough to say that a bare catalogue of them fills fourteen royal octavo columns. The value of these is very unequal. The *Henriade* has by universal consent been relegated to the position of a school reading book, and perhaps does not hold even that very securely. Constructed and written in almost slavish imitation of Virgil, employing for medium a very unsuitable vehicle—the alexandrine couplet (as reformed and rendered monotonous for dramatic purposes)—and animated neither by enthusiasm for the subject nor by real understanding thereof, it could not but be an unsatisfactory performance to posterity. The *Pucelle*, if morally inferior, is from a literary point of view of far more value. It is desultory to a degree; it is a base libel on religion and history; it differs from its model Ariosto in being, not, as Ariosto is, a mixture of romance and burlesque, but a sometimes tedious tissue of burlesque pure and simple; and it is exposed to the objection—often and justly urged—that much of its fun depends simply on the fact that there were and are many people who believe enough in Christianity to make its jokes give pain to them, and to make their disgust at such jokes piquant to others. Nevertheless, with all the *Pucelle's* faults, it is amusing—less so indeed than its author's prose tales, but still amusing. The minor poems are as much above the *Pucelle* as the *Pucelle* is above the *Henriade*. It is true that there is nothing, or hardly anything, that properly deserves the name of poetry in them—no passion, no sense of the beauty of nature, only a narrow "criticism of life," only a conventional and restricted choice of language, a cramped and monotonous prosody, and none of that indefinite suggestion which has been rightly said to be of the poetic essence. But there is immense wit, a wonderful command of such metre and language as the taste of the time allowed to the poet, occasionally a singular if somewhat artificial grace, and a curious felicity of diction and manner on occasions proper to the poet's genius.

The third division of Voltaire's works in a rational order (though it is usually placed later in the editions) consists of his *prose romances* or *tales*. These productions—incomparably the most remarkable and most absolutely good fruit of his genius—were usually, if not always composed as pamphlets, with a purpose of polemic in religion, politics, or what not. Thus *Candide* attacks religious and philosophical optimism, *L'Homme aux Quarante Écus* certain social and political ways of the time, *Zadig* and others the received forms of moral and metaphysical orthodoxy, while some are mere lampoons on the Bible, the unfailing source of Voltaire's wit. But (as always happens in the case of literary work where the form exactly suits the author's genius) the purpose in all the best of them disappears almost entirely. It is in these works more than in any others that the peculiar quality of Voltaire—ironic style without exaggeration—appears. That he learned it partly from St. Évremond, still more from Anthony Hamilton, partly even from his own enemy Le Sage, is perfectly true, but he gave it perfection and completion. There is no room to analyze it here; but if one especial peculiarity can be singled out, it is the extreme restraint and simplicity of the verbal treatment. Voltaire never dwells too long on his point, stays to laugh at what he has said, elucidates or comments on his own jokes, guffaws over them, or exaggerates their form. The famous "pour encourager les autres" (that the shooting of Byng did "encourage the others" very much is not to the point) is a typical example, and indeed the whole of *Candide* shows the style at its perfection.

The fourth division of Voltaire's work, as we shall rank it here, his *historical work*, is the bulkiest of all except his correspondence, and some parts of it are or have been among the most read, but it is far from being the best, or even among the best. The universally known small treatises on Charles XII. and Peter the Great are indeed models of clear narrative and ingenious if somewhat superficial grasp and arrangement in little of considerable subjects. The so-called *Siècle de Louis XIV.* and *Siècle de Louis XV.* (the latter inferior to the former but still valuable) contain a great miscellany of interesting matter, treated by a man of great acuteness and unsurpassed power of writing, who had also had access to much important private information. But even in these books defects are present, which appear much more strongly in the singular *olla podrida* entitled *Essai sur les Mœurs*, in the *Annales de l'Empire*, and in the minor historical works of which there are many. These defects are an almost total absence of any comprehension of what has since been called the philosophy of history, the constant presence of gross prejudice, frequent inaccuracy of detail, and, above all, a complete incapacity to look at any thing except from the narrow standpoint of a half pessimist and half self-satisfied *philosophe* of the 18th century. Attempts have been made to argue that Voltaire's admitted want of catholicity and appreciation was merely the fault of his time; but, while this would be an insufficient plea if granted, it is not the fact. Montesquieu, to name no other of his contemporaries, had if not a perfect yet a distinct sense of the necessity of dealing with other times and other manners so as to take to some extent the point of view of the actors; Voltaire had none. And, though he was very far from being an idle man, he cannot be said to have been extraordinarily anxious to secure accuracy of fact.

His work in *physics* concerns us less than any other here; it is, however, not inconsiderable in bulk, and is said by experts to give proof of aptitude.

To his own age Voltaire was pre-eminently a poet and a philosopher; the unkindness of succeeding ages has sometimes questioned whether he had any title to either name and especially to the latter. His largest *philosophical* work, at least so-called, is the curious medley entitled *Dictionnaire Philosophique*, which is compounded of the articles contributed by him to the great *Encyclopédie* and of several minor pieces. No one of Voltaire's works shows his anti-religious or at least anti-ecclesiastical animus more strongly. The various title-words of the several articles are often the merest stalking horses, under cover of which to shoot at the Bible or the church, the target being now and then shifted to the political institutions of the writer's country, his personal foes, etc., and the whole being largely seasoned with that acute, rather superficial, common-sense, but also commonplace, ethical and social criticism which the 18th century called philosophy. The book ranks perhaps second only to the novels as showing the character, literary and personal, of Voltaire; and despite its form it is nearly as readable. The minor philosophical works are of no very different character. In the brief *Traité de Metaphysique* the author makes his grand effort, but scarcely succeeds in doing more than show that he had no real conception of what metaphysic is. His *Philosophe Ignorant* is a clever skit on the contradictions of philosophers, his *Lettres de Memmius* a fair instance of his habit of taking oblique shots at one thing under cover of another and while apparently aiming at a third. And all the minor works commonly called philosophical, though they are voluminous enough, come to little more than the same result.

In general *criticism* and *miscellaneous* writing Voltaire is not inferior to himself in any of his other functions. Almost all his more substantive works, whether in verse or prose, are preceded by prefaces of one sort or another, which are models of his own light pungent *causerie*; and in a vast variety of nondescript pamphlets and writings he shows himself a perfect journalist. In literary criticism pure and simple his principal work is the *Commentaire sur Corneille*, though he wrote a good deal more of the same kind—sometimes (as in his *Life* and notices of Molière) independently, sometimes as part of his *Siècles*. Nowhere, perhaps, except when he is dealing with religion are Voltaire's defects felt more than here. His great acquaintance with stage matters often enabled him to make valuable technical criticism in that department, and his unrivalled acuteness of course served him in literary as in other matters. But he was quite unacquainted with the history of his own language and literature, and more here than anywhere else he showed the extraordinarily limited and conventional spirit which accompanied the revolt of the French 18th century against limits and conventions in theological, ethical, and political matters.

There remains only the huge division of Voltaire's *correspondence* which fills some three thousand pages, double-columned, large, and closely printed, in the compactest editions, which is constantly being augmented by fresh discoveries, and which, according to M. Georges Bengesco, the best living authority, has never been fully or correctly printed, even in some of the parts longest known. In this great mass Voltaire's personality is of course best shown, and perhaps his literary qualities not worse. His immense energy and versatility, his adroit and unhesitating flattery when he chose to flatter, his ruthless sarcasm when he chose to be sarcastic, his rather unscrupulous business faculty, his more than rather unscrupulous resolve to double and twist in any fashion so as to escape his enemies,—all these things appear throughout the whole mass of letters.

After giving an account of Voltaire's personal character, and a sketch of the characteristics of the different sections of his work, his intellectual and literary position in history can be briefly summed up, though the summary is not one to be lightly undertaken. Most judgments of him have been unduly colored by sympathy with or dislike of what may be briefly called his polemical side. When sympathy and dislike are both carefully discarded or allowed for, he remains certainly one of the most astonishing, if not exactly one of the most admirable, figures of letters. That he never, as Carlyle complains, gave utterance to one great thought is strictly true. That his characteristic is for the most part an almost superhuman cleverness rather than positive genius is also true. But that he was merely a mocker, which Carlyle and others have also said, is not strictly true or fair. In politics proper he seems indeed to have had few or no constructive ideas, and to have been entirely ignorant or quite reckless of the fact that his attacks were destroying a state of things for which as a whole he neither had nor apparently wished to have any substitute. In religion he protested stoutly, and no doubt sincerely, that his own attitude was not purely negative; but here also he seems to have failed altogether to distinguish between pruning and cutting down. Both here and elsewhere his great fault was an inveterate superficiality. But this superficiality was accompanied by such wonderful acuteness within a certain range, by such an absolutely unsurpassed literary aptitude and sense of style in all the lighter and some of the graver modes of literature, by such untiring energy and versatility in enterprise, that he has no parallel among ready writers anywhere. Not the most elaborate work of Voltaire is of much value for matter; but not the very slightest work of Voltaire is devoid of value as form. In literary craftsmanship, at once versatile and accomplished, he has no superior and scarcely a rival.

The bibliography of Voltaire is a very large subject, and it has for years been the special occupation of a Roumanian diplomatist of much erudition and judgment, M. Georges Bengesco, the first volume of whose work was published at Paris in 1882. The latest, and on the whole the best, edition of the works is that completed not long ago by M. Louis Moland in 52 volumes (Paris, Garnier); the handiest and most compact is that issued in 13 volumes royal octavo some fifty years ago by Furne, and kept in print by the house of Didot. Of the earlier editions, though their bulk is an objection, several are interesting and valuable. Especially may be noticed the so-called edition of Kehl, in which Voltaire himself, and later Beaumarchais, were concerned (70 vols., 1785–89); those of Dalibon and Baudouin, each in 97 vols. (from which "the hundred volumes of Voltaire" have become a not infrequent figure of speech); and the excellent edition of Beuchot (1829) in 72 volumes. Editions of separate or selected works are innumerable, and so are books upon Voltaire. There is no really good detailed life of him, with complete examination of his work, in any language as yet, though the works containing materials for such are numerous, and (especially in the case of M. Desnoiresterres) sometimes excellent. In English the essays of Carlyle and Mr. John Morley are both in their way invaluable and to a great extent correct one another. The principal detailed life in our language is that of an American writer, Mr. James Parton, which gives the facts with very considerable detail and fair accuracy, but with no power of criticism. Fresh correspondence of Voltaire is constantly being discovered, sometimes showing that his published works have been considerably garbled, so that an *édition définitive* from such manuscripts as exist, and containing all the variants of his own constantly altered issues, is likely to be a matter long delayed. (G. SA.)

VOLTERRA, a town of Italy, in the province of Pisa, 51 miles by rail east-southeast from Leghorn, and 35 by road west-northwest from Siena, stands on a commanding olive-clad eminence about 1600 feet above sea-level, and is surrounded by the massive remains of its ancient walls, some 4½ miles in circuit. The most important relic of its Etrurian period is the Porta dell' Arco, an archway of dark gray stone, about 20 feet in height, the corbels of which are adorned with almost obliterated heads, probably representing the guardian deities of the city. Volterra possesses several public buildings of interest, dating from the period of its republican independence in the 13th century. The Palazzo dei Priori, or Palazzo Pubblico (1208–57), is a handsome building, unfortunately somewhat modernized in its windows and mouldings; it contains a very valuable collection of Etruscan antiquities, especially cinerary urns. The cathedral, consecrated in 1120, but enlarged and adorned by Niccolo Pisano in 1254, has a fine pulpit of that period, and on the high altar are sculptures by Mino da Fiesole; in the transept is a remarkably fine Annunciation by Luca Signorelli. The baptistery also, supposed to date in part from the 7th century, largely belongs to the 13th; the font is by Andrea di Sansovino, and the ciborium by Mino da Fiesole. The citadel, now a house of correction, consists of two portions, the Rocca Vecchia, built in 1343 by Walter de Brienne, duke of Athens, and the Rocca Nuova, built by the Florentines (1472). The inhabitants are chiefly employed in the manufacture of vases and other ornaments from alabaster, of good quality, found in the vicinity of Volterra and near Leghorn. The population in 1881 was 5347 (commune 14,063).

Volaterræ (Etrurian *Velathri*) appears to have been one of the twelve confederate cities of Etruria (see ETRURIA, vol. viii. p. 558). It received a military colony under the triumvirate, but is included by Pliny among the municipal towns of Etruria. It was destroyed in the 10th century, and rebuilt under the Othos. In the 12th and 13th centuries it enjoyed free institutions; in the 14th it fell under the power of Florence. Persius the satirist and Daniele da Volterra (see RICCIARELLI) were both natives of the town.

VOLUNTEERS. Although it would be difficult to assign a period when the principle of volunteer organization for national defence was first adopted in England, it is certain that societies to promote this object existed in various parts of the country in the reign of Henry VIII., who in fact granted a charter in 1537 to the "Fraternity or Guylde of St. George: Maisters and Rulars of the said Science of Artillary as aforesaid rehearsed for long-bowes Cros-bowes and Hand-Gonnes." This ancient volunteer corps is now the Honorable Artillery Company of London, whose muster rolls have borne the names of many distinguished personages, including John Milton. Although the Honorable Artillery Company has always been a distinct volunteer association, it was at one time (notably during the wars of the Commonwealth) a centre of instruction for the City trained bands, whose officers indeed were required by statute to be members also of the company. It is an interesting fact in connection with this company that there exists at Boston, U. S., a volunteer corps bearing the name of the "Antient and Honorable Artillery Company of Massachusetts." This legacy of the pilgrim-fathers was formed in 1638 after its London prototype, and its Puritan origin is still recognized in the "election sermon" which celebrates the anniversary of its formation.

It was not, however, until 1779 that volunteer organization became an integral part in national defence. In that year, Ireland being threatened with invasion by France and Spain, a levy of 40,000 Protestants was made by the gentry in the north. The energy and patriotism thus promptly manifested no doubt averted the impending danger, but not without unexpected results, for the volunteers then enrolled availed themselves of the opportunity to assert claims on their own account for the extension of civil liberty. The close of the 18th and the early part of the present century saw in Great Britain itself a more complete development of the national instinct for self-defence, when the aggressive wars of France, following upon the Revolution of 1789, threatened the safety of the United Kingdom. Between 1794 and 1804 successive Acts of Parliament were passed providing for the administration and discipline of the volunteer force, which, in 1805, when invasion by the first Napoleon was imminent, amounted to 429,165 men (70,000 of whom were Irish). When peace, however, was restored, this force was disbanded, with the exception of the yeomanry or volunteer cavalry, which continues to this day.

After an interval of nearly half a century the warlike attitude of France, under Napoleon III., caused the British once more to arm for the protection of their country. This long interval, however, had been used differently by the respective nations. England, from a questionable economy, had allowed both army and navy to decline in strength and efficiency; France on the other hand, by the energetic development of her military and naval power, and the early application of steam to ships of war, brought the possibilities of the invasion of England in 1846 within measurable distance, while a feeling of hostility was fostered and inflamed by her political writers. England at this time was awakened to the gravity of the situation by the publication of a well-known letter from the duke of Wellington, then commander-in-chief, to Sir John Burgoyne,[1] followed by a well-timed pamphlet by General Sir Charles Napier, entitled *The Defence of England by Corps of Volunteers and Militia*. This characteristic sketch of the true principles of defence for a free people became seven years later the basis of the volunteer organization.

In 1857 the French press became more and more menacing. The United States had dismissed the resident British minister, and in consequence reinforcements had to be sent to Canada and New Brunswick. The war going on in China required an army and employed a fleet. The Indian Mutiny taxed the resources of England to the uttermost, while at home (save the actual garrisons) an unsatisfactory reserve of barely 36,000 militia was all that could be counted on. This threatening condition of affairs tended to aggravate, if not to produce, a serious commercial panic. It was then that the volunteer movement began, and by a popular impulse.

A circular letter, dated 12th May, 1859, from the secretary for war to the lord-lieutenants of counties in Great Britain, authorized the formation of volunteer corps. The statute under which the general enrolment took place was the same that had governed the organization of the volunteer force in the beginning of the century.[2] The main provisions of that Act, however, were found inapplicable to the altered conditions under which invasion was now possible (through the application of steam); they failed also to meet the new system entertained of maintaining the volunteer force on a permanent footing in peace. A new Act was therefore passed, the most important provision of which[3] was that apprehended invasion should constitute a sufficient reason for the sovereign to call out the volunteers for service, in lieu of the old condition which required the actual appearance of the enemy upon the coast. To carry this provision into effect, the apprehension has to be first communicated to parliament, or if parliament is not sitting declared by the queen in council and notified by proclamation. The volunteers are thereupon bound to serve in Great Britain until released by a proclamation declaring the occasion to have passed. When so called out, they receive pay on the army scale.

---

[1] *Life and Letters of Field-Marshal Sir John Burgoyne.*

[2] 44 Geo. III cap. 54.

[3] Volunteer Act, 1863, s. 17.

The force thus brought into existence is composed of corps of light horse, artillery, engineers, mounted rifles, and rifle volunteers. There exist also in connection with the Admiralty special volunteer corps for the defence of the coast-line, called "Royal Naval Artillery Volunteers." The term "corps" possesses no tactical signification. Any body of persons, great or small, whose offer of service the queen has accepted constitutes a "corps." The property belonging to the corps is vested in the commanding officer, and is administered by a committee of officers under the rules of the corps. These rules are in the first instance agreed on at a general meeting of officers and men, and, having received the queen's approval, become legal, and may be enforced by a magistrate's order. The commanding officer has power to dismiss a man from the corps, and a volunteer not on actual service may terminate his engagement on giving fourteen days' notice.

Volunteers, when assembled under arms, whether for actual service or for exercise, are under the command of the commander-in-chief or of general or other field-officers of the regular army appointed to command them, who must be senior in rank to every officer of the volunteers present. But it is a fundamental law that volunteers are to be led by their own officers. For the purposes of training, a permanent staff of adjutants and sergeant-instructors is provided from the regular army.

The formation of corps constituted as described was so rapid that in the course of a few months in 1859–60 a force of 119,000 volunteers was created. For administrative purposes, and for instruction, small corps were grouped in their several counties into "administrative battalions." This provisional arrangement has since been abolished (a questionable measure), and the small "corps," deprived of much of the status necessary as nuclei of battalions in time of war, are converted into constituent parts or companies of what had been their administrative battalions. These latter are now not only constituted "corps" in the meaning of the Act, but are called "consolidated corps," though their constituent parts are widely scattered. Though this arrangement is convenient during peace, confusion would probably result under pressure of apprehended invasion.

On the 7th March, 1860, the queen held a levee in London, at which 2500 officers of volunteers were presented. On the 23d June a royal review was held in Hyde Park, when 21,900 volunteers marched past; and at Edinburgh on the 7th August another royal review took place, at which 22,000 volunteers from the northern corps were under arms.

Public confidence was thus restored, but yet more remained to be done. An end had to be put to the ever-recurring panics that paralyzed from time to time the commercial system of the country. The Government, which in the beginning had tolerated rather than encouraged the movement, now followed the lead of public opinion, and decided on maintaining the volunteer force as a part of the regular defensive system of the country. The *personnel* of the volunteer corps (with a few essential exceptions) thereupon underwent a change. The wealthy and professional classes, who had at first joined the ranks in anticipation of war, cared no longer to bear arms. Their places were taken by the artisan class, which added materially to the number and permanence of the force. But, as contributions and subscriptions now flagged, it became evident that public grants would have to be voted for its maintenance. A Royal Commission was therefore appointed in 1862 to inquire into the requirements of the volunteers, as well as to determine the conditions on which the public grant should be given, and a scale of ordinary and special capitation allowances, subject to regulation, was fixed on that commission's recommendation.

It was not to be expected that this so-called mushroom army should escape a certain amount of professional ridicule, which the inefficiency of the old volunteers associated with the name. Nor was this tendency unmixed with apprehension in certain quarters that the public grants voted for the force might in some way affect the interests of the regular army. But a generous appreciation and sympathy took the place of adverse criticism, as the earnestness of the volunteers and their devoted loyalty became apparent. Nor were they unsuccessful in their own efforts to keep pace with modern military training, and even to introduce improvements. Lord Elcho, a prominent leader of the volunteer movement, revived in the National Rifle Association the ancient English pastime of practicing at the butts. The queen herself fired the first shot (a bull's-eye) at Wimbledon in 1860, and thus inaugurated those great national meetings where many thousands compete annually for prizes, the aggregate value of which has now reached £14,680 [$71,344.80], with 126,463 entries.

Colonel Harcourt followed Lord Elcho in establishing the National Artillery Association, whose meetings are held annually at the School of Gunnery at Shoeburyness. The volunteers in this arm of the force are more than 40,000 strong, and belong chiefly to the mechanic class. Their aptitude to learn the use of the great modern ordnance which their presence at the School of Gunnery encourages, and their steady discipline when in garrison, have impressed the officers of the Royal Artillery with their value as a reserve for manning the coast defences, as well as for the equipment of field batteries. Special provision has now been made for the latter, on the condition that the batteries are fully horsed by the volunteers, and that three complete detachments of men per gun are maintained in training.

The regular attendance of detachments of colonial volunteers at these great annual national competitions has exercised for some years past a silent and beneficial influence, by fostering the military sympathy of the colonies with the mother country as regards the interests of imperial defence. This feeling found practical expression in the expedition to the Soudan in 1885.

A novel and peculiarly national arm was also introduced in 1860 by Colonel Bower, then master of the Hambledon hounds at Droxford, who trained members of the hunt as a corps of mounted riflemen to occupy ground from point to point across country.

When the number of hunting men in Great Britain is considered, all of whom would be ready to turn out, thus equipped, to harass the flank of an invader, beyond reach even of his cavalry, some estimate may be formed of the value of this contribution to the plan of defence.

The late Lord Ranelagh, another leader of mark among volunteers, initiated the great Easter volunteer field-days at Brighton and elsewhere. His views, at first opposed, are now officially acted on, and the annual Easter assemblies have developed into manœuvres, interesting as well as instructive to all engaged. The Easter holidays afford also opportunity to artillery volunteers to go into garrison in forts, as at Sheerness and other coast works, where means of practicing are available. Facilities in camp instruction are also extended to volunteers in summer, an arrangement which enables the small scattered corps to unite for drill. As many as 100,000 volunteers were in camp in 1887.

Perhaps the most important organization of all, alike for the service of the army and the auxiliary forces, is that known as the "Engineer and Railway Transport Corps," formed by the patriotic exertions of the late Charles Manby, civil engineer, and a lieutenant-colonel in the corps. The term "corps" presents in this case a council of officers composed of the following elements: (1) eminent civil engineers; (2) the general managers of the main lines of railway; (3) the chief employers of labor. These officers have the rank of lieutenant-colonel. There are also other officers of the same classes, subordinate to the above, and not belonging to the council. The functions of the corps include (*a*) the arrangement and the carrying into effect of any sudden and general concentration of troops to oppose invasion, and (*b*) the rapid execution of works upon the railways and lines of defence by the means at the disposal of the great contractors directed by the civil engineers. The ready labor power of this useful corps is estimated at from 12,000 to 20,000 navvies, with tools, barrows, and commissariat complete. It has already performed important service in tabulating, and printing at great private cost, complete time-tables and special reports for six general concentrations against possible invasion. A special return was also prepared by the corps (the first of its kind) of the entire rolling stock of all the railways in Great Britain. This important work—which is corrected and republished annually—shows where the requisite numbers of carriages of every description can be obtained for the composition of troop trains.

The opinion of military judges has been that the main weakness of the whole volunteer system rests with the officers. But this judgment has undoubtedly been modified of late years by the eagerness displayed by the officers of all ranks to become capable leaders of their men. While advantage is taken of the facilities provided by the Government—such as schools of instruction, temporary attachment to regular and militia regiments, and half-yearly examinations in tactics—officers of volunteers are making progress among themselves by initiating societies in various parts of the country for the study and discussion of military subjects, war games, etc. Individually, some officers have already taken a prominent position as students in the art of war. One of these, Colonel Macdonald, C. B., commanding the Edinburgh Rifle Volunteers, has originated important improvements in the system of infantry drill, and his modifications have been approved in principle by the adjutant-general. An ambulance service has been organized, and a scheme for battalion transport brought out.

The foregoing organization has not exhausted the resources of volunteer national defence. Science and commercial wealth combined are now creating an outer line,—the former for the defence of the Humber, Tees, Tyne, Mersey, etc., by means of volunteer marine mining corps, and the latter by the institution of the Naval Volunteer Defence Association, having for its object the protection of merchant ships, by fitting out in British ports a number of merchant vessels to serve in time of war as a cordon around the coasts of the kingdom, within which the shipping may pass in security.

There is yet another weak point, of equal importance, in the personal equipment of the volunteers, which, as a rule, is deficient for field service. But now that the jurisdiction has been transferred from the lord-lieutenants of counties to the crown, the whole subject of equipment for the field is intrusted to direct and responsible military authority.

The still graver question arises as to the issue of warlike stores in general in the time of national danger. Notwithstanding that such stores are already partially in possession of the services, the issue to the *levée en masse* (or augmentation of the volunteer force) alone will be a matter of extreme difficulty for one arsenal to manage. This difficulty will be best understood by the following statement. The volunteer force in Great Britain at the beginning of the century numbered 359,165. Since then, however, the population has nearly doubled, Therefore, supposing all other conditions to be equal, the number that would now come forward to defend the country would be about 700,000, or 481,800 more than the present peace footing of the volunteer force. One arsenal is not sufficient to sustain the strain that would then be put upon it. Strategically considered also, the situation of that at Woolwich is not such as to justify the accumulation there of all the warlike material the nation would have to depend on. A central arsenal, if not a northern one as well, appears to be a national necessity.

The existence of the volunteer force averts conscription for the country's defence, and it forms, as the first Lord Brougham characterized it, a "national insurance." The cost to the country is trifling compared with the magnitude of the issues, being in 1885 £767,400 [$3,729,564] for 218,000 "efficient" volunteers entitled to the public grant, that is £3, 8s. 6d. [$16.64] per volunteer, or barely 6d. [12 cts.] per head of the population to be defended. The value of the volunteer force is not, however, to be estimated by the numbers actually enrolled. It is in fact, in its present form, a great training school of citizen soldiers, through which thousands pass annually into a reserve ready to join in case of need. And every year of its valuable service confirms the wisdom of Sir Charles Napier's last words of advice to his countrymen, viz., "Militia and volunteers are the proper forces to prepare for danger in time of peace." (M. M'M.)

VOLUSENUS, **Florentius** (that is, **Florence Wilson** or **Wolsey**, though in an English letter he writes himself **Voluzene**), a Scottish humanist of the first half of the 16th century, whose elegant Latinity, but still more the thoughtful beauty of his Christian philosophy, claims for him a high place among the scholars of his age. That he was born near Elgin, and studied philosophy at Aberdeen, as is stated in the notice of his life published in 1619 by Thomas Wilson in *Adamsoni Poemata Sacra*, may be only an inference (though probably a just one) from a passage in the dialogue *De Tranquillitate Animi*, more than half of which consists of a description of the abode of tranquillity, based on a dream that, as we are told, came to the author when he had been a student of philosophy for four years, after a conversation on the pleasant banks of the Lossie with John Ogilvy, afterwards rector of Cruden. Proceeding to Paris, he became tutor to a nephew (or really a bastard son) of Cardinal Wolsey, and this connection led to repeated visits to England, where he was well seen by the king, and formed, with men like John Fisher, Stephen Gardiner, and Thomas Cromwell, connections that were not dissolved by Wolsey's fall, for he was in England as late as 1534. In Paris he knew George Buchanan, who afterwards wrote a graceful epitaph on his friend's death, and found patrons in the cardinals Jean de Lorraine (to whom he dedicated in 1531 a Latin exposition of Psalm xv.) and Jean du Bellay. With the latter he started in 1534 for Italy, but, being detained by sore sickness at Avignon, found a new patron in the bishop of the diocese, the learned and pious Sadolet, who procured for him the mastership of the school at Carpentras, with a salary of seventy crowns. Volusenus felt himself a little out of place in a grammar school, all his tastes leaning to philosophy, and it would seem that from Carpentras he made repeated visits to Lyons (where Gesner saw him, still a young man, in 1540), probably also to Italy, where he made many friends, perhaps even to Spain, for Alciat tells us that he had acquired French, Italian, and Spanish "par frequentation des nations." A letter of Sadolet from Rome in 1546 shows that he had then resolved to return to Scotland, and was concerned to know what course he should hold in the religious dissensions of the time. He died on the journey, however, at Vienne in Dauphiné.

The authorities for the life of Wilson are well brought together by Irving in the *Lives of Scottish Writers* (1839); with the exception of two letters in the *Bannatyne Miscellany*, vol. i., the most important of them had already been collected in Wishart's edition of the *De Tranquillitate* (8vo, Edin., 1751). Irving, however, overlooked Wilson's earliest works, *Fl. Vol. ad illustr. Dom. Card. Lotharingorum Ps. xv. Enarratio* (4to, Paris, 1531) and *Fl. Vol. Britanni in Psalmum nobis* 50 *Hebræis vero* 51 *ad . . . Stephanum Wintoniensem Episcopum Enar.* (4to, Paris, 1532). These show that his linguistic studies embraced Hebrew as well as Greek and Latin. Wilson's reputation, however, rests on the beautiful dialogue already cited, and first printed by Gryphius at Lyons in 1543. From internal evidence it appears to have been composed about that time, but the subject had exercised the writer for many years. The dialogue shows us Christian humanism at its best, not yet breaking with the church and somewhat afraid of authority, but open to new light, tolerant and yet believing. Volusenus is a great admirer of Erasmus, but censures in him a lack of purity in his Latin and a certain want of philosophy. Latinity and philosophical training are his own distinguishing points, but his philosophy is Christian and Biblical rather than classical or scholastic. To analyze his argument would here be out of place; the title of the dialogue itself shows that he takes a fresh and independent view of the chief good of Christian ethics, and it is sufficient to observe that from this point of view he ultimately reaches a doctrine as to the witness of the Spirit and the assurance of grace which breaks with the traditional Christianity of his time and contains ethical motives akin to, though not identical with, those of the German Reformation. The verses which occur in several parts of the dialogue, and the poem which concludes it, give Wilson a place among Scottish poets, but not nearly so high as that which he occupies among philosophical writers on Christianity.

VONDEL, JOOST VAN DER (1587–1679), Dutch poet. See HOLLAND, vol. xii. p. 97.

VORAGINE, JACOBUS DE (*c.* 1230–1298), archbishop of Genoa, is said to have been born at the little village of Varaggio, near Savona, about the year 1230. He entered the order of St. Dominic in 1244, and is said to have preached with great success in many parts of Italy, as well as to have taught in the schools of his own fraternity. From the office of prior in 1267 he was raised to be provincial of all Lombardy. This post he held till 1286, when he was removed at the meeting of the order in Paris. He also represented his own province at the councils of Lucca (1288) and Ferrara (1290). On the last occasion he was one of the four delegates charged with signifying Nicholas IV.'s desire for the deposition of Munio de Zamora, who had been master of the order from 1285, and was deprived of his office by a papal bull dated April 12, 1291. In 1288 Nicholas empowered him to absolve the people of Genoa for their offence in aiding the Sicilians against Charles II. Early in 1292 the same pope, himself a Franciscan, summoned James to Rome, intending to consecrate him archbishop of Genoa with his own hands. James reached Rome on Palm Sunday (March 30), but only to find his patron ill of a deadly sickness, from which he died on Good Friday (April 4). The cardinals, however, "propter honorem Communis Januæ," determined to carry out this consecration on the Sunday after Easter, and thus, to quote his own words, "he returned with joy to his own city, and was reverently received by the people." If we may trust Echard, he was a model bishop and especially distinguished himself by his efforts to appease the civil discords of Genoa. His death seems to have taken place in June, 1298. He was buried in the Dominican church at Genoa. A story, mentioned by Echard as unworthy of credit, makes Boniface VIII., on the first day of Lent, cast the ashes in the archbishop's eyes instead of on his head, with the words, "Remember that thou art a Ghibelline, and with thy fellow Ghibellines wilt return to naught."

Jacobus de Voragine has left us a list of his own works. Speaking of himself in his *Chronicon Januense*, he says, "While he was in his order, and after he had been made archbishop, he wrote many works. For he compiled the legends of the saints (*Legendæ Sanctorum*) in one volume, adding many things from the *Historia Tripartita et Scholastica* and from the chronicles of many writers." The other writings he claims are two volumes of "Sermons concerning all the Saints"[1] whose yearly feasts the church celebrates. Of these volumes, he adds, one is very diffuse, but the other short and concise. Then follow *Sermones de Omnibus Evangeliis Dominicalibus* for every Sunday in the year; *Sermones de Omnibus Evangeliis, i.e.*, a book of discourses on all the Gospels, from Ash Wednesday to the Tuesday after Easter; and a treatise called "*Marialis*, qui totus est de B. Maria compositus," consisting of about 160 discourses on the attributes, titles, etc., of the Virgin Mary. In the same work the archbishop claims to have written his *Chronicon Januense* in the second year of his pontificate (1293), but it extends to 1296 or 1297. To this list Echard adds several other works, such as a defence of the Dominicans, printed at Venice in 1504, and a *Summa Virtutum et Vitiorum Guillelmi Peraldi*, a Dominican who died about 1250. James is also said to have translated the Old and New Testaments into his own tongue. "But," adds Echard, "if he did so, the version lies so closely hid that there is no recollection of it."

His two chief works are the *Chronicon Januense* and the *Golden Legend* or *Lombardica Hystoria*. The former is partly printed in Muratori (*Scriptores Rer. Ital.*, ix. 6). It is divided into twelve parts. The first four deal with the mythical history of Genoa from the time of its founder, Janus the first king of Italy, and its enlarger, a second Janus, "citizen of Troy," till its conversion to Christianity "about twenty-five years after the passion of Christ." Part v. professes to treat of the beginning, the growth, and the perfection of the city; but of the first period the writer candidly confesses he knows nothing except by hearsay. The second period includes the Genoese crusading exploits in the East, and extends to their victory over the Pisans (*c.* 1130), while the third reaches down to the days of the author's archbishopric. The sixth part deals with the constitution of the city, the seventh and eighth with the duties of rulers and citizens, the ninth with those of domestic life. The tenth gives the ecclesiastical history of Genoa from the time of its first known bishop, St. Valentine, "whom we believe to have lived about 530 A.D.," till 1133, when the city was raised to archiepiscopal rank. The eleventh contains the lives of all the bishops in order, and includes the chief events during their pontificates; while the twelfth deals in the same way with the archbishops, not forgetting the writer himself.[2]

The *Golden Legend*, one of the most popular religious works of the Middle Ages, is a collection of the legendary lives of the greater saints of the mediæval church. The preface divides the ecclesiastical year into four periods corresponding to the various epochs of the world's history, a time of deviation, of renovation, of reconciliation, and of pilgrimage. The book itself, however, falls into five sections: (*a*) from Advent to Christmas (*cc.* 1–5); (*b*) from Christmas to Septuagesima (6–30); (*c*) from Septuagesima to Easter (31–53); (*d*) from Easter Day to the octave of Pentecost (54–76); (*e*) from the octave of Pentecost to Advent (77–180). The saints' lives are full of puerile legend, and in not a few cases contain accounts of 13th-century miracles wrought at special places, particularly with reference to the Dominicans. The author is very particular in giving the derivation of proper names, and indeed generally supplies a copious choice of alternatives. He is nearly always careful to assign a yearly date to the saints he treats of, but seldom, if ever, mentions their feast days. As he reaches the great seasons of the year he inserts treatises dealing with their significance and interpretation. These we have for Advent, Christmas, Good Friday, Easter, Whitsunday, etc. The last chapter but one (181) "De Sancto Pelagio Papa," contains a kind of history of the world from the middle of the 6th century; while the last (182) is a somewhat allegorical disquisition, "De Dedicatione Ecclesiæ."

The *Golden Legend* was translated into French by Jean Belet de Vigny in the 14th century. It was also one of the earliest books to issue from the press. A Latin edition is assigned to about 1469; and a dated one was published at Lyons in 1473. Many other Latin editions were printed before the end of the century. A French translation by Master John Bataillier is dated 1476; Jean de Vigny's appeared at Paris, 1488; an Italian one by Nic. Manerbi (Venice, 1475); a Bohemian one at Pilsen, 1475–79, and at Prague, 1495; Caxton's English versions, 1483, 1487, and 1493; and a German one in 1489. Several 15th-century editions of the *Sermons* are also known, and the *Mariale* was printed at Venice in 1497, and at Paris in 1503.

VORARLBERG, the most western division of the Austrian-Hungarian monarchy, is bounded on the N. by Bavaria, on the W. by the Lake of Constance,

---

[1] Printed without name or place, 1484.

[2] The adjective "golden" has been transferred from this to other works of the author.

Liechtenstein, and Switzerland, on the S. by Switzerland, and on the E. by Tyrol. Though united for administrative purposes with Tyrol, it enjoys a constitution of its own, and ranks as a separate member of the empire. It is emphatically an Alpine region, being traversed by various spurs of the Rhætian Alps (Arlberg, Bregenzer Wald, etc.), attaining a height of 6000 to 9000 feet, and even possessing a few small glaciers. The name is derived from the Arlberg Pass (*i.e.*, Adlerberg, or Eagle's Mountain, 5895 feet), separating it from Tyrol and forming the means of communication between Innsbruck and the Lake of Constance. The pass is now traversed by a railway, the tunnel under the Arlberg itself (opened Oct., 1884) being 6½ miles in length. Vorarlberg is watered by numerous small streams, most of them flowing into the Rhine, which is in contact with the west side of the crownland for a distance of about 20 miles. About one-third of the surface (almost exactly 1000 square miles in extent) is occupied by pasture, upwards of one-sixth by forests, one-seventh by meadows, and only one-twentieth by arable land. In correspondence with these figures, we find that the chief employments of the inhabitants are cattle-rearing, dairy-farming, and forestry.

In 1881 the district contained 61,115 cattle, and cheese is produced in large quantities. Grain is cultivated in the valley-bottoms, but not more than enough is raised to cover the home consumption; potatoes, fruit, and wine are also produced. The manufacturing industry is also by no means unimportant, occupying nearly 30 per cent. of the population. The chief branch is the spinning and weaving of cotton, which is carried on with special vigor in the neighborhood of the towns and larger villages. A characteristic industry is the construction of wooden chalets, which are exported to Switzerland by water. Many of the men spend the summer in Switzerland as masons and laborers, returning to their homes in winter. In 1881 the population numbered 107,373, nearly all of Teutonic stock and the Roman Catholic faith. The chief towns, none of which are large, are Bregenz (4736 inhabitants), the capital, and the port of Austria on the Lake of Constance, Bludenz (3150 inhabitants), Feldkirch (3600), and Dornbirn. Vorarlberg belongs to the see of Brixen, the prince-bishop of which is represented by a vicar-general at Feldkirch. The provincial diet consists of twenty-one members, including the vicar-general. The crownland sends two representatives to the imperial parliament.

Vorarlberg is formed out of the old duchies and countships of Bregenz, Feldkirch, Bludenz, Sonnenberg, and Hohenems, all of which had come into the possession of the house of Austria by the 14th century, chiefly by purchase. Prior to 1782 it was counted part of Hither Austria, but since then it has been administratively united with Tyrol. The peace of Pressburg (1805) assigned it to Bavaria, along with northern Tyrol, but it was restored to its old allegiance in 1814.

VORONEZH, a government of southern Russia, is bounded by Tamboff on the N., Saratoff and the Don Cossacks on the E., Kharkoff on the S., and Kursk and Orel on the W., and has an area of 25,448 square miles. It occupies the southern slopes of the Middle-Russian plateau, and its average elevation is from 450 to 700 feet above sea-level. The surface is hilly, and broken by ravines in the west (where two ranges of chalk hills separated by a broad valley run north and south), but flat and low to the east of the Don. Devonian sandstones crop out in the north, but farther south these are covered with chalk. Glacial clays with northern erratics spread as far south as Voronezh, and extensive areas are covered with Lacustrine clays and sands. The soil is very fertile, owing to the large prevalence of the black earth; it becomes, however, sandy towards the east. Voronezh lies on the border between the forest and meadow-region of Middle Russia and the southern steppes; the forests rapidly disappear as one advances south, and those which in the time of Peter the Great still covered the upper parts of the tributaries of the Don, and were used for shipbuilding, are now almost entirely destroyed. Less than one-tenth of the entire area is under wood, and both timber and firewood have to be imported.

The Don traverses Voronezh from north to southeast, watering it for more than 400 miles; it is an important channel for the export of corn, tallow, and other raw produce, as well as for the import of wood, floated from the north. Its tributary the Voronezh is also navigated, and another large tributary, the Vorona, flows through the eastern part of the government. Many other small streams flowing into the Don intersect the territory, but the influence of the dry steppes begins to make itself felt; there are no lakes, and marshes persist only in the valleys. The climate is therefore continental, and, although the mean temperature at Voronezh is 42.7° F., that of January is as low as 8.3° and that of July as high as 74.2°.

The population is steadily increasing, and reached 2,532,840 in 1883 as against 1,974,400 in 1860. It is Little Russian in the southwest (from 35 to 40 per cent., according to different estimates), and Great Russian elsewhere. There are also a few German colonies with some 3500 inhabitants, and a few Poles (2000).

Agriculture is the chief occupation, and corn is exported to a considerable amount. The average crops from 1883 to 1885 reached 3,467,800 quarters of rye, 901,600 of wheat, 958,000 of oats, 1,680,000 of various grains, and 960,100 of potatoes. 17,000 acres were under beet (176,000 cwts. in 1885); tobacco is also largely cultivated, and the crop of 1885 yielded 1,723,000 ℔. The sunflower has also been much cultivated of late for oil. The Voronezh horses enjoy a high reputation in Russia, as also do its cattle, and cattle-breeding has advanced during the last thirty years. In 1883 there were 535,500 horses, 649,100 cattle, and 1,348,100 sheep. Bees are kept in many villages, and honey is gathered to the annual amount of more than 10,000 cwts. Market-gardening and fishing are also of importance. The manufactures are of recent growth; the production reached £2,066,000 [$1,004,076], in 1884, the chief products being spirits, oil, sugar, woollens, and tallow. Wheat and other grains, flour, flax, tallow and hides, wool and cattle are the chief items of export.

Voronezh is divided into twelve districts, the chief towns of which are Voronezh (56,185 inhabitants in 1885), Biryutch (4435), Bobroff (3660), Bogutchary (4230), Korotoyak (1840), Nijne-Dyevitsk (2635), Novokhopersk (8015), Ostrogozhsk (8610), Pavlovsk (8390), Valuiki (4425), Zadonsk, with a great monastery (9940), and Zemlyansk (3870). These are mostly mere administrative centres; and several villages, such as Buturlinovka (21,700), Kalatch (13.000), and Vorontsovka (12,000), have larger populations and more commerce.

VORONEZH, capital of the above government, is situated on a high bank of the river of the same name, 365 miles by rail to the south of Moscow. It is almost entirely built of wood, and only recently began to reacquire importance as an entrepôt on the railway which connects Moscow with the Sea of Azoff. It has a military school of cadets, gymnasiums for boys and girls, and a number of schools for elementary education. Its theatre, now rebuilt, has a name in the history of the Russian stage, and the town was also the birthplace of two peasant poets, to whom we owe some of the finest examples of Russian poetry—Koltsoff and Nikitin. A memorial to the former has been erected on a public promenade. A few factories for cleansing wool and for the preparation of tallow and oil, as well as some distilleries, have arisen of late. The population of the town increased from 39,800 in 1860 to 56,185 in 1885. It is now an important entrepôt for corn, flax, tallow, hides, sugar, wood, and coal from the Don; the railway traffic amounts to 2½ million cwts., and that of the Razdelnaya junction, close by, is nearly thrice that amount.

Voronezh was founded in 1586, as a fort against Tartar raids, on a site which had been occupied from the 11th century by a Khazar town, but had been deserted during the 14th and 15th centuries. Four years afterwards it was burned by the Tartars, but again rebuilt, and soon became an important trading place. Its wooden fort was rebuilt in 1672. Peter I. recognized its importance, and in 1694 erected on an island of the river a wharf, where a flotilla of sixty-six boats (2546 guns and 17,000 men) was built, under the direction of Dutch shipbuilders, for the conquest of Azoff. It thus became the basis of further advances towards the Black Sea. The town was almost completely destroyed by fire in 1703, 1748, and 1773, but was always rebuilt and has steadily developed.

VORTEX MOTION. See HYDROMECHANICS, vol. xii. pp. 468–469 *sq.*

VOSGES, a mountain range of central Europe, stretching along the west side of the Rhine valley in a north-northeast direction, from Basel to Mainz, for a distance of 150 miles. Since 1871 the southern portion, from the Ballon d'Alsace to Mont Donon, has been the political boundary between France and Germany. There is a remarkable similarity between the Vosges and the corresponding range of the Black Forest on the other side of the Rhine; both lie within the same degrees of latitude and have the same geological formation; both are characterized by fine forests on their lower slopes, above which are open pasturages and rounded summits of a uniform altitude; both have a steep fall to the Rhine and a gradual descent on the other side. The Vosges in their southern portion are mainly of granite, with some porphyritic masses, and of a kind of red sandstone (occasionally 1640 feet in thickness) which on the western versant bears the name of "grès Vosgien."

Orographically the range is divided from south to north into four sections: the Grandes Vosges (62 miles), extending from Belfort to the valley of the Bruche; the Central Vosges (31 miles), between the Bruche and the Col de Saverne; the Lower Vosges (30 miles), between the Col de Saverne and the source of the Lauter; and the Hardt (25 miles). The rounded summits of the Grandes Vosges are called "ballons." The departments of Vosges and Haute Saâne are divided from Alsace and the territory of Belfort by the Ballon d'Alsace or St. Maurice (4100 feet). Thence northwards the average height of the range is 3000 feet, the highest point of all, the Ballon de Guebwiller (Gebweiler) or Soultz, rising on the east to a height of 4680 feet. The Col de Saales, between the Grandes Vosges and the central section, is 1900 feet high; the latter is both lower and narrower than the Grandes Vosges, the Mont Donon and other chief heights not exceeding 3300 feet. The railway from Paris to Strasburg and the Rhine and Marne Canal traverse the Col de Saverne (1085 feet). No railway crosses the Vosges between Saverne and Belfort, but there are very good carriage roads over the passes of Bussang (2410 feet) from Remiremont to Thann, the Schlucht (3746 feet) from Gérardmer to Munster, the Bon Homme (3100 feet) from St. Dié to Colmar, and from St. Dié to St. Marie-aux-Mines (2625 feet). The Lower Vosges are a sandstone plateau ranging from 1000 to 1850 feet high, and are crossed by the railway from Hagenau to Sarreguemines, defended by the fort of Bitche. The Hardt, a sterile region, covered with heath and low brushwood, has for its highest point the Donnersberg (Mont Tonnerre), 2264 feet high; it is traversed through deep ravines by the railways from Deux-Ponts to Landau, and from Kaiserslautern to Spires and Worms. Meteorologically, the difference between the eastern and western versants of the range is very marked, the annual rainfall being much higher and the mean temperature being much lower in the latter than in the former. On the eastern slope the vine ripens to a height of 1300 feet; on the other hand, its only rivers are the Ill and other shorter streams, which afford water-power rather by their rapid fall than by their abundance. The Moselle, Meurthe, and Sarre all rise on the Lorraine side. Moraines, boulders, and polished rocks testify the existence of the glaciers which formerly covered the Vosges. The lakes, surrounded by pines, beeches, and maples, the green meadows where hundreds of cows with tinkling bells peacefully graze, and the fine views of the Rhine valley, Black Forest, and snow-covered Swiss mountains combine to make the district charmingly picturesque. The lower heights and buttresses of the main chain on the Alsatian side are covered with numerous castles, generally in ruins, in connection with which curious legends and interesting historical incidents are told. At several points on the main ridge, especially at St. Odile above Ribeauvillé (Rappoltsweiler), are the remains of a wall of unmortared stone with tenons of wood, 6 to 7 feet thick and 4 to 5 feet high, called the pagan wall (Mur Payen). It was certainly used for local defence in the Middle Ages, and archæologists are divided as to whether it was built for this purpose by the Romans, or before their arrival.

VOSGES, a frontier department of eastern France, was formed in 1790, for the most part of territory previously belonging to Lorraine, with fragments of Franche-Comté, Champagne, and Alsace. The portion belonging to Alsace was ceded to Germany in 1871. Lying between 47° 48′ and 48° 32′ N. lat., and 5° 22′ and 7° 10′ E. long., the department is bounded by Alsace-Lorraine on the E. and by the departments of Meurthe-et-Moselle on the N., Meuse on the N.W., Haute-Marne on the W., and Haute-Saône on the S. The Vosges Mountains form a natural boundary on the E. The highest point is the Hohneck (4482 feet) near the Schlucht. The south of the department is traversed by the Monts Faucilles (2000 feet), which form part of the European watershed, separating the basins of the Rhine and the Rhone. The Moselle and the Meuse, tributaries of the Rhine, have the largest drainage areas in the department; a small district in the northwest belongs to the basin of the Seine (Ornain and Marne), the rest to that of the Rhone. The Moselle rises in the Col de Bussang, and in a N.W. course of 75 miles receives the Moselotte and Vologne on the right; the Mortagne and the Meurthe on the right and the Madon on the left bank also belong to Vosges, though they join the Moselle outside the department. The source of the Saône is on the southeast slope of the Monts Faucilles, and the Canal de l'Est follows the course of the Coney, a tributary of the left bank. The height above the sea, the northward exposure of the valleys, and the impervious subsoil combine to make the climate severe; the average temperature at Épinal (1070 feet) is 49° F. The annual rainfall is 24 inches at Épinal, 31 at St. Dié, and more in the mountains.

Of a total area of 1,452,181 acres, arable land occupies 603,201 acres, grass 199,839, wood 361,526, heath, pasture, and uncultivated land 81,486, and vineyards 12,054. The live stock in 1881 included 31,811 horses (of a small but strong breed), 357 asses and mules, 143,827 cattle, 45,634 sheep, 81,488 pigs, 19,615 goats, more than 17,000 dogs, 500,000 head of poultry; 17,952 beehives yielded 43 tons 7 cwts. of honey and 18 tons 11 cwts. of wax. 872 tons of cheese were made at Gérardmer. The crops in 1884 were—wheat 1,911,470 bushels, meslin 494,483, rye 710,627, barley 103,262, oats 3,225,755, buckwheat 63,409, potatoes 17,787,404, dry vegetables 45,974, fodder beetroot 25,060 tons, tobacco 33 tons, hops 79 tons, hemp seed 138 tons, hemp 99 tons, linseed 39 tons, flax 22 tons, hemp, flax, and poppy oils 94 tons, colza seed 206 tons, fodder 457,383 tons, wine 2,869,000 gallons (average of preceding ten years 3,964,441). The department stands first in France for the extent and importance of the woods under forest rule, though only third for the actual area of forest land. The state owns one-third of the forests, private individuals one-fifth, and the communes the rest. Oaks, beeches, hornbeams, birches, aspens, and maples thrive on the plains, beeches and oaks on the higher grounds, and firs, beeches, and pines on the mountains. The annual value of timber produced is £280,000 [$1,360,800], and 9,000,000 fir planks, besides other kinds, are annually cut in 300 sawmills. Traces of gold are found, and the department contains silver and lead mines, copper ore, iron ore (4530 tons of iron annually), zinc, manganese, cobalt, and antimony. In 1884, 681 tons of coal were mined, and in 1882, 1595 tons of peat were dug; 1336 persons are employed in 432 quarries of marble, sandstone, granite, and building and lithographic stones. The department is rich in hot, cold, sulphate, sodic, calcium, iron, bicarbonate, and gaseous mineral springs. Those at Plombières were known to the Romans. 37,000 hands are employed in the manufacture of pig and cast iron (for all which wood is the chief fuel) and wares of iron and steel. The cotton industry (135,000 looms and 423,724 spindles) has been largely developed since 1871; canvas and linen are woven at Gérardmer (3000 looms). The manufacture of cloth employs 500 workmen, of lace 1000, embroidery by the hand and loom 40,000 workwomen, silk spinning 1000 spindles. Wool is spun and hosiery manufactured. Coopers' work (over 300 tons) is exported, as are also sabots. At Épinal several hundred workmen are engaged in the manufacture of images; and musical instruments are made at Mirecourt. 1000 workmen are employed in glass-works, and 1937 in paper-mills (10,000 tons of paper and cardboard). The department contains in all 409 industrial establishments; 200,000 tons of coal are imported. There are 281 miles of railway, 177 of national roads, and 3096 of other roads. The Eastern Canal connects the Saône with the

Moselle and Meuse. The population in 1881 was 408,862, of whom 189,176 were engaged in agriculture and 131,253 in manufactures; the population in 1886 was 413,707. The department forms the diocese of St. Dié, has its court of appeal and academy at Nancy, belongs to the district of the corps d'armée of Châlons-sur-Marne, and is divided for administrative purposes into 5 arrondissements (Épinal, Mirecourt, Neufchâteau, Remiremont, St. Dié), 29 cantons, and 530 communes. The chef-lieu is Épinal.

VOSS, Johann Heinrich (1751–1826), German poet, archæologist, and translator, was born at Sommersdorf in Mecklenburg on the 20th February, 1751. In the same year his father, a farmer, removed from Sommersdorf to Penzlin. From 1766 to 1769 Voss attended school at Neubrandenburg. In the latter year, in consequence of misfortunes which had overtaken his father, he was obliged to accept a tutorship in the family of a private gentleman near Penzlin. He went to Göttingen in 1772, in response to the invitation of Boie, whose attention he had attracted by poems contributed to the Göttingen *Musenalmanach.* At Göttingen he studied with enthusiasm ancient and modern literature, and became one of the leading members of the famous "Dichterbund." In 1775 Boie made over to him the editing of the *Musenalmanach*, which he continued to issue for many years. He married Boie's sister, Ernestine, in 1777, and in the following year he accepted the position of rector at Ottendorf in Hanover. As the climate of Ottendorf did not suit his health, he resigned this office in 1782, and went as rector to Eutin, where he remained until 1802. He then lived for some time in Jena, but in 1805 he accepted a call to a professorship at Heidelberg. He died at Heidelberg on March 29, 1826.

Voss was a man of a remarkably independent and vigorous character, and he achieved distinction in several kinds of literary activity. In 1785–95 he published in two volumes a collection of original poems, to which he afterwards made many additions. The best of these works is his idyllic poem "Luise," in which he sought, with much success, to apply the style and methods of classical poetry to the expression of modern German thought and sentiment. In his *Mythologische Briefe* (2 vols., 1794), in which he attacked the ideas of Heyne, in his *Antisymbolik* (2 vols., 1824–26), written in opposition to Creuzer, and in other writings he made important contributions to the study of mythology. He was also prominent as an advocate of the right of free judgment in religion, and at the time when some members of the Romantic school were being converted to the Roman Church he produced a strong impression by a powerful article, in *Sophronizon,* on his friend Friedrich von Stolberg's repudiation of Protestantism. It is, however, to his work as a translator that Voss chiefly owes his place in German literature. All his renderings of the works of ancient writers indicate not only sound scholarship but a thorough mastery of the laws of German diction and rhythm. The most famous of his translations are those of Homer, which were published together, in 4 volumes, in 1793. Of these the one generally preferred is the translation of the *Odyssey*, as originally issued in 1781. He also translated Hesiod, Theocritus, Bion and Moschus, Virgil, Horace, Tibullus, Propertius, and other classical poets, and he prepared a critical edition of Tibullus. In 1818–29 was published, in 9 volumes, a translation of Shakespeare's plays, which he completed with the help of his sons Heinrich and Abraham, both of whom were scholars and writers of considerable ability.

See Paulus, *Lebens- u. Todeskunden über J. H. Voss* (1826), and Herbst, *J. H. Voss* (2 vols., 1872–76).

VOSSIUS, Gerardus Johannes (1577–1649), classical scholar and theologian, was born near Heidelberg in 1577. His father Johannes Vos, a native of the Netherlands, had fled as a Protestant from the persecutions in his own country into the Palatinate, and became pastor in the village near Heidelberg where Gerard was born; but, as he was a Calvinist, the strict Lutherans of the Palatinate caused him once more to become a wanderer. In 1578 he settled at Leyden as student of theology in the university, and finally as pastor at Dort, where he died in 1586, leaving Gerard an orphan. Here the boy received his education, until he entered the theological college and then the university of Leyden. He there became the lifelong bosom friend of Hugo Grotius, and pursued with great zest the study of the classics, Hebrew, ecclesiastical history, and theology. In 1600 he was made rector of the high school at Dort, where he devoted himself to philology and historical theology. From 1614 to 1619 he filled the office of director of the theological college at Leyden. The moderation of his theological views and his abstention from controversy brought him under the suspicion of heresy, in consequence of which he escaped expulsion from his office only by resignation (1619). The year before he had published his valuable work the *Historia Pelagiana*, which his enemies considered favored the views of the Arminians or Remonstrants. But in the year 1622 he received the appointment of professor of rhetoric and chronology, and subsequently of Greek, in the university. In 1624 the university of Cambridge offered him a professorship, which he declined. Two years afterwards another unsuccessful effort was made to induce him to settle in England, but he accepted from Archbishop Laud a prebend in Canterbury cathedral of the value of £100 [$486] per annum, without residence, coming over to England to be installed in 1629, when he was made LL.D. at Oxford. In 1632 he left Leyden to take the post of professor of history in the newly founded Athenæum at Amsterdam, which he held till his death, March 17, 1649.

He was one of the great scholars of the world, and his character added lustre to his learning. His works, of which a complete edition appeared at Amsterdam, 1695–1701, in 6 vols. fol., are philological, historical, and theological. He made invaluable contributions to the correct study of Latin grammar and of the Greek and Latin historians. He was amongst the first to treat theological dogmas and the heathen religions from the historical point of view. His principal works are *Historia Pelagiana* (1618); *Etymologicum Linguæ Latinæ* (1662); *Commentariorum Rhetoricorum Libri VII.* (1606); *De Historicis Græcis Libri III.* (1624); *De Historicis Latinis Libri III.* (1627); *De Theologia Gentili* (1642); *Dissertationes Tres de Tribus Symbolis, Apostolico, Athanasiano, et Constantinopolitano* (1642).

See Nicéron, *Mémoires pour servir à l'Histoire des Hommes Illustres*, vol. xiii., Paris, 1730; Herzog's *Realencyklopädie*, art. "Vossius."

VOSSIUS, Isaac (1618–1689), son of the preceding, was born at Leyden in 1618, and was carefully educated by his father. After three years spent on a learned tour through England, France, and Italy, which he used in making the acquaintance of the first scholars and the great libraries of those countries, and from which he brought back many valuable MSS., he accepted in 1648 an invitation to the court of the brilliant Queen Christina of Sweden, whom he taught Greek. He declined the offer of the chair of history at Amsterdam vacated by his father's death, and continued for some years in Sweden, with occasional visits to Holland. In 1658 he finally left Sweden. His father's merits and his own learning procured him favor with Louis XIV. of France and in England. In 1670 he came to reside in England, was made LL.D. of Oxford, and in spite of notorious looseness of morals and levity of charater received a canonry at Windsor from Charles II. in 1673, residing in the castle, where he died in February, 1689.

His learning was great, and he rendered valuable services in connection with ancient history, antiquities, chronology, and geography, though they were marred by the admixture of great levity and want of judgment. To him is owing the first Greek text of the six shorter epistles of Ignatius (1646). He published valuable editions of the geographer Scylax (1639), of Justin (1640), of Pomponius Mela (1658), and of Catullus (1684). In his various dissertations on chronology he maintained the greater accuracy of the system of the Septuagint in comparison with that of the Hebrew text, and generally asserted the greater genuineness of the Greek translation as compared with the Massoretic text. He inherited his father's valuable library, which, to the great sorrow of Evelyn, went after his death back to Holland.

Comp. Nicéron's *Mémoires*, vol. xiii.

VOTKINSK, an iron-work in the Urals, in the

Russian government of Vyatka, 47 miles north of Sarapul, and 8 miles from the Kama, was founded in 1756. Its population reached 15,480 in 1885. Together with the Kamsk iron-work, Votkinsk was till lately one of the chief Government establishments for the construction of steamers for the Caspian flotilla, as well as of locomotives for the Siberian railway, and it has long been renowned for its excellent tarantasses and other smaller iron-wares, as well as for its knitted goods. No large orders having been received from the Government, a number of workmen recently united into an "artel" or co-operative society for the manufacture of agricultural machinery, already known throughout Russia for its excellence and cheapness.

VOUET, Simon (1590–1649), French painter, born at Paris, January 9, 1590, passed many years in Italy, where he married, and established himself at Rome, enjoying there a high reputation as a portrait painter. Louis XIII. recalled him to France, lodged him in the Louvre with the title of First Painter to the Crown, and gave him a considerable salary. All royal work for the palaces of the Louvre and the Luxembourg was placed in his hands; the king became his pupil; he formed a large school, and renewed the traditions of that of Fontainebleau. Amongst his scholars was the famous Lebrun (who raised on the foundations laid by his master the tyranny by which he dominated the whole artistic world during the reign of Louis XIV.), Lebrun's rival Errard, Louis Lerambert, the two Testelins, Poerson, and Dorigny. Vouet was an exceedingly skilful painter, especially in decoration, and executed important works of this class for Cardinal Richelieu (Rueil and Palais Royal) and other great nobles. His better easel pictures bear a curious resemblance to those of Sassoferrato, but, being much in demand, he fell into mannerisms, and of the enormous quantity of work produced by himself or with the aid of his pupils little has survived worth study. Almost everything he did was engraved by his sons-in-law Tortebat and Dorigny.

VOW, a solemn undertaking to do something which is held to be acceptable to the Deity. In the antique religions mere prayer, without some material expression of homage, was not held to be a complete or normal act of worship (*cf.* Sacrifice). Supplications, therefore, were generally presented to the Deity in connection with a sacrifice, or, if the moment of need was one at which a ritual offering could not well be presented, the prayer for help was naturally accompanied by a promise to present a gift at a future time. Thus prayer together with a vow is a sort of imperfect act of worship, which has to be completed by the discharge of the vow at the sanctuary. So in Greek the same word *εὐχή* is equally applicable to the prayer which opened a service of sacrifice and to a vow taken at the commencement of an enterprise or in other time of need. So too the Latin *votum* means both "vow" and "desire." In the Old Testament, in like manner, it is generally a sacrifice or gift at the sanctuary which is promised in vows, and the word "vow" (*néder*) means also "a votive sacrifice," as distinguished from obligatory sacrifices (piacular offerings and stated festal sacrifices; 1 Sam. i. 21).

The vows of which we read in the Old Testament and in classical authors are generally conditional on the fulfilment of the petition with which they are coupled. Such vows are made on occasions of special need, or difficulty (Ps. lxvi. 13 *sq.;* Pliny, *H. N.*, viii. 21 [57], "tum præcipuus votorum locus est cum spei nullus est"), as before a perilous enterprise (Gen. xxviii. 20; Judg. xi. 30). The payment offered may be a victim for the altar, or any other gift which the ritual of the religion acknowledges as acceptable. But, as vows are generally made on extraordinary occasions, the thing promised will often be exceptional in kind or magnitude. The vow of Jephthah (Judg. xi.) is a case in point, and also illustrates by an extreme example the principle that a vow once taken must be fulfilled at any cost. This principle was so far modified in later times, in Israel, that exceptional vows were by law redeemed at a valuation (Lev. xxvii.). Hannah's vow, devoting her unborn son to the service of the sanctuary (1 Sam. i. 11), would have fallen under this law. Moreover, the law provided that the vow of an unmarried daughter or of a wife might be disallowed by the father or husband respectively (Numb. xxx.). On the other hand, a widow or a divorced woman was free to make what vow she pleased. These provisions are important evidence of the legal position of woman in Hebrew society, and also, *ex silentio*, as implying that Hebrew sons (at least after infancy) were not subject to *patria potestas* of the Roman kind.

Of ordinary vows a common type in antiquity was a promise made in peril by sea, sickness, or other straits, to suspend in a temple a picture or other symbol of the danger against which the Divine aid was implored. This usage passed into Christianity and survives in Catholic countries, where votive pictures and models of eyes, hands, etc., cured in answer to prayer, are still seen in churches. At the council of Lestines (743 A.D.) the use of such models was condemned as a pagan practice.

In point of obligation, vows were analogous to oaths (Numb. xxx. 2); their sanction was not human but Divine (Deut. xxiii. 21). Thus slackness or fraud in the fulfilment of vows is the mark of an age of declining faith (Mal. i. 14; Ḥárith, *Moall.*, l. 69 Arnold: Lucian, *Jupiter Trag.*, c. 15; *cf.* Eccles. v. 4). Among the Arabs the speedy fulfilment of vows was favored by a rule of abstinence from certain enjoyments and conveniences (*iḥrām*), which custom imposed till the vow was fulfilled. This appears to have been the ancient practice of other Semitic nations also; among the Hebrews it survives in the Nazarite vow (see Nazarite), and probably also in the *esār* or *issār* (interdict), which is mentioned along with vows in Numb. xxx., and is described in verse 13 as "an oath of abstinence to afflict the soul,"—words which seem to show that fasting is specially contemplated. As there is no ascetic tendency in Hebrew religion, in which fasting and similar observances have not positive religious value, but are only expressions of penitent supplication, it seems reasonable to interpret the oath of abstinence by the aid of the examples in Psalm cxxxii. 2 *sq.*, Acts xxiii. 12 (*cf.* also 1 Sam. xiv. 24 *sq.*), and to understand it, like the Arabian *iḥrām*, as an obligation of abstinence till a positive vow was fulfilled. The detail in the Psalm, "I will not enter my house or rest in my bed till," etc., has its parallel in Arabia and in Syrian heathenism (Sūr. ii. 185—where to enter the house from behind is an evasion of the rule; Lucian, *Dea Syr.*, § 55; *cf.* Wellhausen, *Skizzen* iii. 117). It is to be observed that in Arabia, where there was little or no development of obligatory ritual sacrifices, offerings were usually votive, and vows were often simple and not conditional promises; so too in Deut. xxiii. 23, Lev. vii. 16, vows are closely associated with free-will offerings. A purpose of sacrifice formed at a distance from a sanctuary naturally found expression in a vow. Occasions of sacrifice are not frequent in nomad life and it may be conjectured that the earliest vows were simply deferred sacrifices, without the element of bargaining with the Divinity which is prominent in later times. The simple vow presupposes that the sanctuary or the customary day of sacrifice is remote; the conditional vow, on the other hand, may often be made at the sanctuary itself, where the Godhead is nearest to man (Gen. xxviii. 20; 1 Sam. i. 11; *Iliad*, vii. 93).

In Christian times vows to present a material gift (*vota realia*) have been less important than vows to adopt a certain course of life (*vota personalia*), a change which naturally followed from the modification of the idea of sacrifice in Christianity (see Sacrifice). The personal vows recognized by the Catholic church are of various kinds, covering all manner of actions religiously meritorious (*e.g.*, pilgrimage or crusading); but the most prominent have been vows of abstinence (fasting, chastity), to which the growth of asceticism gave a positive value. Most important of all is the monastic vow of poverty, chastity, and obedience (see Monachism). The presupposition of all such vows is that there is a higher life of godliness, which cannot be attained to by Christians at large, and which all are not bound to attempt, although there is merit in consecrating oneself to it. From this point of view it came about in process of time that vows of self-consecration were viewed as necessarily perpetual. To fall back from a purpose of higher life was not at all the same thing as never to have formed such a purpose. Hence, *e.g.*, the vow of chastity, which Cyprian still regards as terminable by marriage in the case of virgins who have not strength to persevere in continence, was declared to be of perpetual obligation as early as the council of Ancyra (314 A.D.). On the other hand, the church was careful to guard against the rash assumption of vows, by requiring certain formalities in the act, and by the institution of the novitiate, as a period of probation. The power of the pope to dispense from vows, which appears in the *Decretals*, was of later growth. Protestantism, denying the superior merit of the ascetic life, rejects all perpetual vows, and indeed shows little favor to vows of any kind. (W. R. S.)

VRANCX, Sebastian, born about 1572, was a painter of the Antwerp school, of very moderate ability. Most of his pictures represent scenes of war, such as the sack of towns, cavalry combats, and the like. Though occasionally vigorous in drawing, his paintings are dull and heavy in tone. The date of his death is uncertain.

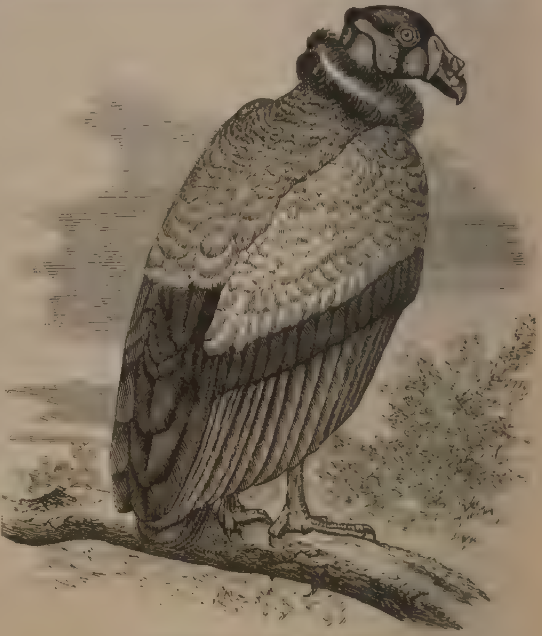
VULCAN, the old Roman fire-god, answering to the Greek Hephæstus (*q.v.*), with whom he was confounded by the ancients. The etymology of the name is uncertain: it has been proposed to derive it from the root *var*, "warm"; *ulka* in Sanscrit is a firebrand. How closely Vulcan was identified with the fire, regarded as a person, appears from the stories of the birth of Cæculus and Servius Tullius, both of whom were called sons of Vulcan, and were supposed to have been conceived by virgins who had been impregnated by sparks of fire from the hearth. At Rome his temple was in the Campus Martius outside the city walls. But there was also a place sacred to him in the comitium. It was not a temple, but only a raised area, called the Volcanal. It was said to have been founded by Romulus, and a lotus tree in it was thought to be as old as the city. Statues of persons who or whose statues had been struck by lightning were sometimes set up in the Volcanal. There was a festival of Vulcan called the Volcanalia on August 23d, in which the people threw animals into the fire instead of themselves. On the 7th of June there was a fishermen's festival, with games, held under the superintendence of the "prætor urbanus," and the fish were brought to the Volcanal and sacrificed to the god instead of human victims. Another festival of Vulcan was the Tubilustria, or purification of trumpets, on May 23d, Vulcan being regarded as the father of trumpets. At Ostia there was a festival of Vulcan (Volcanalia) presided over by a "prætor sacris Volcani faciundis," and at Ostia there were also a temple and a pontifex of Vulcan. At Rome there was a "flamen" of Vulcan, who sacrificed to Maia, wife of Vulcan, on the 1st of May. According to others the name of Vulcan's wife was Majesta.

VULCANO. See Lipari Islands, vol. xiv. p. 688.

VULGATE. See Bible, vol. iii. p. 559.

VULTURE, the name of certain birds whose best-known characteristic is that of feeding upon carcases, and these birds, owing to this obscene habit, are in many hot countries regarded with favor as useful scavengers. The genus *Vultur*, as instituted by Linnæus, is now restricted by ornithologists to a single species, *V. monachus*, of which more presently, the other species included therein by him, or thereto referred by succeeding systematists, being elsewhere relegated (*cf.* Lämmergeyer); but the most important taxonomic change that has been introduced is that by Prof. Huxley (*Proc. Zool. Society*, 1867, pp. 462–464), who pointed out the complete structural difference between the Vultures of the New World and those of the Old, regarding the former as constituting a distinct Family, *Cathartidæ* (which, however, would be more properly named *Sarcorhamphidæ*), while he united the latter with the ordinary diurnal Birds-of-Prey as *Gypaetidæ*. This arrangement seems to overlook the signification of some considerable distinctions, and to the present writer it would appear more reasonable to recognize the existence of a Family *Vulturidæ*, confined to the true Vultures of the Ancient Continent, equal in rank to the *Falconidæ*, while fully admitting the claim made on behalf of the New-World forms for the same standing.

The American Vulture may be said to include four genera: (1) *Sarcorhamphus*, the gigantic Condor, the male distinguished by a large fleshy comb and wattles; (2) *Gypagus*, the King-Vulture, with its gaudily-colored head and nasal caruncle; (3) *Catharista*, containing the so-called Turkey-Buzzard of English-speaking Americans with its allies; and (4) *Pseudogryphus*, the great Californian Vulture—of very limited range on the western slopes of North America, and threatened with speedy extinction through the use of poison. Though all these birds are structurally so different from the true Vultures of the Old World, in habits the *Vulturidæ* and *Sarcorhamphidæ* are much alike, and of several of the latter—particularly of the Condor and the Turkey-Buzzard—we possess rather elaborate accounts by excellent observers, as Darwin, Alexander Wilson, and Mr. Gosse whose works are readily accessible.



King-Vulture (*Gypagus papa*).

The true Vultures of the Old World, *Vulturidæ* in the restricted sense, are generally divided into five or six genera, of which *Neophron* has been not unjustifiably separated as forming a distinct Subfamily, *Neophroninæ*,—its members, of comparatively small size, differing both in structure and habit considerably from the rest. One of them is the so-called Egyptian Vulture or Pharaoh's Hen, *N. percnopterus*, a bird whose delicacy of build and appearance contrast forcibly with its choice of the most filthy kind of food. It is a well-known species in some parts of India,[1] and thence westward to Africa, where it has an extensive range. It also occurs on the northern shores of the Mediterranean, and on three occasions has strayed to such a distance from its usual haunts as to have twice suffered capture in England, and once even in Norway. Of the genera composing the other Subfamily, *Vulturinæ*, space is wanting to say much. *Gyps* numbers seven or eight local species and races, on more than one of which the English name Griffon has been fastened. The best known is *G. fulvus*, which by some authors is accounted "British," from an example having been taken in Ireland, though under circumstances which suggest its appearance so far from its nearest home in Spain to be due to man's intervention. The species, however, has a wider distribution on the European continent (especially towards the northeast) than the Egyptian Vulture, and in Africa nearly reaches the Equator, extending also in Asia to the Himalaya; but both in the Ethiopian and Indian Regions its range inosculates with that of several allied forms or species. *Pseudogyps* with two forms—one Indian, the other African—differs from *Gyps* by having 12 instead of 14 rectrices. Of the genera *Otogyps* and *Lophogyps* nothing here need be said; and then we have *Vultur*, with, as mentioned before, its sole representative, *V. monachus*, commonly known as the Cinereous Vulture, a bird which is found from the Straits of Gibraltar to the sea-coast of China.[1] Almost all these birds inhabit rocky cliffs, on the ledges of which they build their nests.

---

[1] In the eastern part of the Indian peninsula it is replaced by a smaller race or (according to some authorities) species, *N. gingianus*, which has a yellow instead of a black bill.

The question whether Vultures in their search for food are guided by sight of the object or by its scent has long excited much interest, and the advocates of either opinion have warmly contended in its behalf. Without denying to them the olfactory faculty, it seems to be now generally admitted, notwithstanding the assertions to the contrary of Waterton and a few more, that the sense of sight is in almost every case sufficient to account for the observed facts. It is known that, directly a camel or other beast of burden drops dead, as the caravan to which it belonged is making its way across the desert, Vultures of one sort or another appear, often in considerable numbers, though none had before been observed by the ordinary traveller, and speedily devour the carcase over which they are gathered together. The mode in which communication is effected between the birds, which are soaring at an immense height, seems at first inexplicable, but Canon Tristram has suggested (*Ibis*, 1859, p. 280) the following simple solution of the supposed mystery:

> "The Griffon who first descries his quarry descends from his elevation at once. Another, sweeping the horizon at a still greater distance, observes his neighbor's movements and follows his course. A third, still further removed, follows the flight of the second; he is traced by another; and so a perpetual succession is kept up so long as a morsel of flesh remains over which to consort. I can conceive no other mode of accounting for the number of Vultures which in the course of a few hours will gather over a carcase, when previously the horizon might have been scanned in vain for more than one, or at the most two, in sight."

The Canon goes on to suppose that in this way may be explained the enormous congregation of Vultures in the Crimea during the siege of Sevastopol, where they had before been scarce: "the habit of watching the movements of their neighbors" may "have collected the whole race from the Caucasus and Asia Minor"—he might have added the Balkans—"to enjoy so unwonted an abundance." Doubt may be entertained whether the last supposition be correct, but none as to the accuracy of the first. (A. N.)

VYATKA, or VIATKA, a government of northeastern Russia, with Vologda on the N., Perm on the E., Ufa and Kazañ on the S., and Nijni Novgorod and Kostroma on the W., has an area of 59,124 square miles. It has on its northern boundary the flat water-parting which separates the basins of the Northern Dwina and Volga, and its surface is an undulating plateau of from 800 to 1400 feet above sea-level, deeply grooved by rivers and assuming a hilly aspect on their banks, broken up as they are by ravines. Permian sandstones, marls, and limestones cover it; over these is boulder clay, with extensive forests and marshes. The Kama rises in the northeast, and, after making a wide sweep through Perm, flows along its southeastern boundary, while the whole of the government is watered by the Vyatka and its numerous tributaries. Both the Kama and the Vyatka are navigable, as also are several of their tributaries; the Izha and Votka, which flow into the latter, have important iron-works on their banks. As many as 1,700,000 cwts. of corn, iron, hides, leather, tallow, timber, and wooden wares were loaded in 1883, at the landing-places of Vyatka, while the traffic on the Kama is still more important. There are no railways, but the province is traversed by the great highway to Siberia, and two other roads by which goods from the south are transported to loading places on the Vytchegda and the Yug to be shipped farther north to Archangel. Lakes are numerous, and vast marshes are met with everywhere, especially in the north; three-quarters of the area are under forests. The climate is very severe, the average yearly temperature being 36° F. at Vyatka (January, 8.2°; July, 67.0°), and 35° at Slobodskoi (January, 3.5°; July, 65.3°).

The population (2,859,000 in 1883, as against 2,170,221 in 1861), though sparse on the average, is somewhat dense in the better-situated valleys. The bulk consists of Great Russians (81 per cent.), but there are also considerable remains of the aboriginal Votiaks (250,000), Tcheremisses (about 150,000), Tartars, Tepters, Permians, and even Bashkirs. Mohammedans number about 100,000, and pagans (Tcheremisses and Votiaks) about 11,000. The Votiaks (Otiaks), a Finnish stem of the Permian group, call themselves Ot, Ut, or Ud, and the Tartars call them Ar, so that it is supposed that they may be akin to the Ars of the Yenisei. They are middle-sized, with fair hair and eyes, often red-haired; and the general structure of the face and skull is Finnish. By their dialect they belong to the same branch as the Permians. They are excellent agriculturists, very laborious, and excel in bee-keeping.

The soil is fertile, especially in the valleys of the south; rye, barley, oats, buckwheat, and to some extent wheat are grown. The crops of 1885 were—rye, 4,006,000 quarters; oats, 3,957,000; barley, 734,000; wheat, 98,000; potatoes, 231,000 quarters. Corn is exported to the Kama or to the north, as also are flax and hemp. There is no want of natural meadows in the south, and cattle-rearing prospers. The Vyatka horses, a fine breed, though rather small, are well known throughout Russia. There were in 1883 706,600 horses, 925,100 cattle, and 1,446,400 sheep. Attempts are being made to introduce finer breeds of cows and sheep.

Industries are developing steadily, there having been in 1884 684 establishments which employed 9700 workmen, and showed a yearly return of £1,510,000 [$7,338,600.00]. They include distilleries (£885,600 [$4,304,016.00]), iron-works, chemical works, tanneries, soap and glass works, and cotton and paper mills. VOTKINSK (*q.v.*) has a considerable yearly production of agricultural machinery and steam-engines. The crown manufactory of guns at Izhevsk works up yearly 10,000 cwts. of steel. Domestic trades give occupation to more than 40,000 persons, and their returns in 1884 reached £706,800 [$3,435,048.00]. The manufacture of wooden vessels, window frames, doors, furniture, sledges, and carts supplies a considerable export trade to the steppe provinces of the lower Volga. Domestic weaving produces, it is estimated, about 5,400,000 yards of linen every year. Many peasants have nevertheless to leave their homes in search of work, either as "burlaki" for shipping and dragging boats or as porters; hunting and bird-catching still have some importance in the forest tracts.

Trade is considerable,—iron, copper, tar, pitch, glass, leather, paper, timber, and wooden wares, as also corn, hides, flax, linseed, honey, and other raw produce being exported to Nijni Novgorod, Orenburg, and Siberia; while groceries and various manufactured goods are imported.

Vyatka is one of those few governments of Russia where the *zemstvo*, consisting to a great extent of representatives of the peasantry, has succeeded in creating a series of educational institutions, without incurring the displeasure of the Government. It distinguishes itself very favorably by its schools, libraries, surgeons, and hospitals in villages, and by its elaborate house-to-house statistical descriptions of several districts, and statistical publications. There were in 1884 641 primary and 22 secondary schools.

---

[1] The geographical range of the various species of Vultures has been exhaustively treated by Mr. Sharpe (*Journ. Linn. Society*, Zoology, xiii. pp. 1-26, pls. i.-ix.).

Vyatka is divided into eleven districts—those of Vyatka (24,480 inhabitants in 1885); Elabuga (9750); Głazoff (1945); Kotelnitch (4490); Małmyzh (3400); Nolinsk (3990); Orłoff (3380); Sarapul (12,370); Słobodskoi (9225); Urzhum (5100); Yaransk (2855). Votkinsk (*q.v.*) has 15,480 inhabitants, and Izhevsk has 21,500.

VYATKA, capital of the above government, is situated on the Vyatka river, 653 miles to the northeast of Moscow. It is built mostly of wood, on the steep hills which rise above the river, as well as on their slopes and at their base. Its old walls have been demolished, and its old churches built anew. Two public gardens, a small public library, and the usual educational institutions of a Russian provincial town are all that it can boast of. Its manufactures are insignificant, but its trade in corn, leather, tallow, candles, soap, wax, paper, and furs (exported), and in all kinds of manufactured and grocery wares (imported), is important. The population in 1885 was 24,480.

Vyatka was founded in 1181 by the Novgorodians, under the name of Khłynoff, for the purpose of maintaining their dominion among the Votiaks, Tcheremisses, and Tartars. The squirrel and beaver furs, especially the latter (beaver being then common in the region), and the Vyatka horses, as also wax and honey, were the chief attractions for trade; and, notwithstanding the dangers then encountered on the route to Vyatka and Perm, *via* Vologda, the Novgorod merchants and *ukshuiniki*, (plundering merchants) willingly visited Vyatka and settled there. The town soon grew around the fort, and had to be enclosed within new walls. In 1391 it was plundered by the Tartars, and again in 1477. The power of Novgorod was decaying, and the Moscow princes, always pursuing the same policy of intrigue, and showing themselves ready to take up the cause of the poorer classes against the richer merchants, made advantageous use of internal struggles, and annexed Khłynoff to Moscow in 1489. It received the name of Vyatka in 1780.

VYAZMA, a district town of Russia, in the government of Smolensk, and 109 miles by rail to the northeast of that town, was a populous place as early as the 11th century and carried on a lively trade with Narva on the Gulf of Finland. In the 15th century it fell under the dominion of the Lithuanian princes, but was too close to Moscow to remain in their hands, and was retaken by the Russians by the end of the century. The Poles took it again, however, during the outbreak of 1611, and kept it till the peace of 1634. At present it is an important centre for the trade of Smolensk; corn, hemp, linseed and hemp seed, tallow, and hides are exported to St. Petersburg and Riga, while fish, metals, and manufactured goods are supplied to the neighboring region chiefly by the Vyazma merchants. The population was 13,000 in 1882.

VYERNYI, formerly Ałmaty, capital of the Russian Central-Asian province of Semiryetchensk, is situated on a plateau at the base of the Trans-Ili Alatau, in 43° 16′ N. lat., 47 miles to the south of the Ili river. It was founded in 1854 as a small blockhouse, but from the advantages of its situation—the fertility of the surrounding country, the ample water-supply from the Ałmatinka river, and of timber and firewood from the valleys of the Alatau—it rapidly increased; in 1884 the population numbered 17,545, nearly 3000 of them military. Around the central blocks are several suburbs of wooden and brick houses; the streets are broad and planted with trees. Most of the houses are surrounded by thick growths of poplar and elm as well as by fruit gardens, and the streets and squares are refreshed by channels of running water. The Little Russian, Kirghiz, and Tarantchi villages which surround the town, and have excellent orchards, amply supply Vyernyi with all necessaries. The Tarantchis proved specially helpful to the young settlement on account of their laborious habits and their acquaintance with the agriculture of the steppes. Situated as it is on the site of the old Ałmaty, at the crossing of two roads—from Kuldja to Tashkend, and from Semipalatinsk to Kashgar—Vyernyi carries on an active trade in wheat, rice, corn, tea, oil, and tobacco. The dislocation of the rocks on the northern slope of the Alatau Mountains is the cause of severe earthquakes, the last of which, on June 9, 1887, destroyed or damaged nearly a thousand stone houses in Vyernyi and its neighborhood, killing 326 persons. Slighter shocks were felt up till February, 1888.

VYSHNIY VOŁOTCHOK, a district town of Russia, in the government of Tver, 82 miles by rail to the northwest of that city, owes its importance to its situation in the centre of the Vyshne-Vołotsk navigation system, which connects the upper Volga with the Neva. The portage (*vołok*) of less than 17 miles between the Tvertsa, a tributary of the Volga, and the Tsna, which flows into the Msta and the Volkhoff (Lake Ladoga), had long been used for transporting boats from the one basin to the other, and the canal, which was afterwards dug, soon became one of the most important links of connection between the Volga and the Neva; now, however, the boats prefer the Mariinsk system, and the prosperity of Vyshniy Vołotchok is declining. The inhabitants (11,590 in 1884) support themselves chiefly by shipping, and partly by the cotton industry. The trade is still considerable.

W.

W is simply double *v*, so far as the form goes; but its value, like its name, is double *u*, and it dates back to a time when *u* and *v* had not been fully differentiated, one into a vowel, the other into a consonant (see under U). The oldest form of the letter was *uu*, sometimes *u* only; *e.g.*, uulfheard, uilfrith, in the *Liber Vitæ*, 9th century. Later a peculiar symbol appears, þ, called "wen;" this belonged to the runic alphabet, which the Latin superseded; it undoubtedly represented the *w*-sound. It died out about 1300, probably through the influence of French copyists. As early as the 11th century we find *vv*, later *w*.

The sound denoted by W is a voiced labial formed by rounding the lips so much that the voice cannot escape without friction. In the nature of the case no hard and fast line can be drawn between it and the vowel *u* (any more than between *i* and *y*): it is impossible to say exactly at what point the open position of the lips for *u* ceases and sufficient closure for a definite consonant begins. We may perhaps mark out three noticeable sounds: (1) the clear vowel *u*; (2) a consonant *u*, equivalent to a "glide" in the diphthongs "eu," "ou," etc., *i.e.*, a sound which is held not long enough to be a vowel as forming a syllable by itself, yet without sufficient friction to make a consonant; (3) the consonant *w*. The difference between (2) and (3) may be illustrated by the initial sounds of French "oui" and English "we;" the *ou* in "oui" is a consonant *u*; it does not make a syllable distinct from the following *i*, and so it is not a vowel; yet it is quite distinguishable from the *w* in "we." It is probable, from some slight indications, principally in Sanskrit, that both (2) and (3) were sounds of the Indo-European language. But it could hardly be supposed that they would be kept rigorously distinct in the derived languages; they lie too near together.

It has been already pointed out (see article U) that the representatives of the sound *w* varied much in the different languages. In Greek we find ϝ and sometimes υ (as in *εὐάδε*, etc.); in Latin there was no symbol to distinguish it from the vowel *u*. The English varieties are mentioned above.

For the history of this sound in connection with the velar *k* of the original speech see article Q. This sound died out in most of the derived languages, but left traces in Greek—(1) in the symbol koppa, (2) in the phonetic change called "labialism," by which the slight labial of the original sound developed and eventually changed the guttural explosive into a labial, *e.g.*, $k^{w}ou$ became *ποῦ*. Similarly in Italy the Latin *qu* of "qui," "quantus," etc., preserved the original symbol and sound, whereas the Oscan and Umbrian agreed with the Greek in labializing.

In English the *w*-sound has commonly held its own. It has survived in writing, even in the almost impossible combination *wr*, as in "wrath," "write," "wreck," "wretch," but the sound is lost. In several Old English words the combination *cw* was exchanged for *qu*, as was natural under French influence, *e.g.*, quoth (O.E. cwæð), quell (O.E. cwellan), queen (cwên).

The digraph *wh* denotes the voiceless sound corresponding to the voiced *w*. In the great majority of cases where it occurs it represents original k^{w}, as in who, what (original base $k^{w}a$); these were originally written hwá, hwæt; so also "while" was "hwil," "wheeze" was "hwæs" (Lat. ques-tus). In similar combinations with *l* and *r* the *h* has been lost, as in "loud," formerly "hlúd" (*κλυτός*), raven (hræfn), ring (hring); and in *hw* the *h* seems to have robbed the *w* of its voice (a result denoted by the writing *wh*), and then fallen off here also as an independent sound.

WACE, whom most modern writers without any authority call ROBERT, but who simply calls himself "MAISTRE WACE," was a clerk ("clerc lisant") and trouvère of the 12th century, who was born in Jersey, studied at Caen, and received from Henry II. a prebend at Bayeux with other gifts. Nothing is known certainly of the dates of his birth or death; but the one is conjecturally put at about 1120 and the other at about 1180. He seems to have been much about the reigning house of Normandy and England: he boasts of the kindness of Henry to him (he knew, he says, three Henrys, the third being Prince Henry, the eldest son of Henry II.), and is said by Layamon to have dedicated his *Brut* to Eleanor of Aquitaine. This shadowy personality is partly compensated by a considerable literary work. Wace has left two long romances, the *Roman de Brut* and the *Roman de Rou*, both of which are interesting monuments of Norman French, while the latter is a document of some importance for English history, the writer informing us that he got some direct information from his father, who no doubt was not his only source. The *Roman de Brut*, the longer of the two, is in octosyllabic couplets of a facile and somewhat undistinguished kind. It has generally been regarded as a mere versifying of Geoffrey of Monmouth, a point which turns to some extent of course on the vexed question of Geoffrey's own originals. The *Roman de Rou*, a chronicle of the Norman dukes, is much more interesting and much more vigorously written. The greater part of it is also in octosyllables, but there is a large insertion of assonanced alexandrines in something like the form of the chansons de geste. Wace is not in mere poetical value a very good example of the trouvères, but his subjects give him interest, especially for Englishmen.

The first and hitherto the only edition of the *Brut* is that of Le Roux de Lincy (1838); the *Rou*, after being edited by Pluguet in 1827, has been recently (1877) re-edited by Dr. Hugo Andresen.

WACO, a city and the county seat of M'Lennan county, Texas, U. S., is situated on the west bank of the Brazos river, at the mouth of the Bosque, in an agricultural and pastoral region. It contains Waco university (Baptist) and a female college. The population in 1880 was 7295, more than one-third being negroes.

WADAI. See SOUDAN, vol. xxii. pp. 291–93.

WADDING, LUKE (1588–1657), ecclesiastical historian, born at Waterford in 1588, emigrated with his parents to Spain in early youth, and from Spain passed to Portugal, to study at the Irish College in Lisbon. While still a student, he entered the order of Cordeliers, or Friars Minim, in 1604, taking the name Michael Angelo of St. Romulus, and his early reputation for learning soon obtained for him a professorship of theology at Salamanca. Philip III. of Spain was anxious to procure the formal definition of the Immaculate Conception B. V. M., which had been left open by the council of Trent, and sent Diego de Torres, bishop of Cartagena, as ambassador to the pope for that purpose. Torres, being himself a Cordelier, made choice of Wadding to accompany him on his embassy, and the young divine created so favorable an impression at Rome that another chair of theology was bestowed upon him there, and he was made vice-commissary and procurator-general of his order. He made Rome his headquarters for the remainder of his life, dying there as principal of the Irish College of St. Isidore in 1657.

His earliest publication was an account of the embassy in which he had taken part, Πρεσβεία, *sive Legatio Philippi III. et IV., Hispaniarum Regum, ad Summos Pontifices Paulum V., Gregorium XV., et Urbanum VIII., pro definienda Controversia Immaculatæ Conceptionis Beatæ Mariæ Virginis* (Louvain, 1624, fol.). He contributed, many years later, a work to this question himself, *Immaculatæ Conceptionis Beatæ Mariæ Opusculum* (Rome, 1655, 8vo), now of extreme rarity. He was also author of a treatise on the Hebrew language and other occasional writings, but his literary reputation rests chiefly upon the important works he published in connection with the Franciscan order. The principal of these are *Annales Ordinis Minorum*, 8 vols. folio (Lyons and Rome, 1628–1654), a book of high repute, recast and enlarged by Fonseca, 19 vols. folio (Rome, 1731–1745), and since continued by Michelesi, 1794, and Melchiori de Ceretto, 1844; *Scriptores Ordinis Minorum* (Rome, 1650), to which is subjoined a reprint of a *Syllabus FF. Minorum*, a list of the English Franciscans who were put to death in Tudor days, which had become extremely rare, because most of the original impression was sent to England during the legateship of Cardinal Pole, and was seized and destroyed by order of Queen Elizabeth, because of its reflections upon the character of Henry VIII.; an edition of the *Concordantiæ Bibliorum Hebraicæ* of Calasio, 4 vols. folio (Rome, 1621); *Opera Omnia Joannis Duns Scoti*, 12 vols. in 11, folio (Lyons, 1639); *Sti Francisci Assisiatis Opuscula* (Antwerp, 1623); and *Sti Antonii Paduani Concordantiæ Morales* (Rome, 1624).

WAFERS, as articles of stationery, consist of thin, brittle, adhesive disks, used for securing papers together, and for forming a basis for impressed official seals. Wafers are made of a thin paste of very fine flour, baked between "wafer irons" over a charcoal fire till the thin stratum of paste becomes dry and brittle, and the flour starch is partly transformed into glutinous adhesive dextrin. The cake is cut into round disks with suitable steel punches. Bright non-poisonous coloring matter is added to the paste for making colored wafers. Wafers of gelatin are also made.

WAGER. The law of wagers may be divided for purposes of convenience into two great classes, dealing respectively with procedure and with substantive law. In both classes the legal importance of the wager has tended to diminish.

Procedure.—Determination of cases, civil and criminal, by means of wager or analogous forms of procedure is a characteristic feature of archaic law. The *legis actio sacramenti* at Rome—at first a real, then a fictitious wager— the wager of battle and of law in England, of the highest antiquity in their origin, survived up to a comparatively late period in the history of both legal systems. The form of the wager survived long after its reason had been forgotten. The general prevalence of the wager form of proceeding is perhaps to be attributed to the early conception of a judge as a mere referee who decided the dispute submitted to him, not as an executive officer of the state, but as an arbitrator casually called in (see Maine, *Ancient Law*, c. x.). Wager of battle in England was a mode of trial which was allowed in certain cases viz., on a writ of right (see WRIT), and on appeals of treason and felony (see APPEAL). A full account of the judicial combat will be found under DUEL and ORDEAL. Wager of law (*vadiatio legis*) was a right of a defendant in actions of simple contract debt and of detinue. It superseded the ordeal (itself called *lex* in the Assize of Clarendon and other ancient constitutional records). The mode of proceeding in a wager of law was an interesting relic of that system of compurgation—traced by Blackstone to the Mosaic law, Ex. xxii. 10—which was employed in many legal systems, especially the Scandinavian, and had probably an appreciable effect on the development of the English JURY (*q.v.*). It also has some points of resemblance, perhaps some historical connection, with the *sponsio* and the decisory oath of Roman law, and the reference to oath of Scots law (see OATH). The use of the oath instead of the real or feigned combat —real in English law, feigned in Roman law—no doubt represents an advance in legal development. The technical term *sacramentum* is the bond of union between the two stages of law. In the wager of law the defendant, with eleven compurgators, appeared in court, and he swore that he did not owe the debt or (in detinue) that he did not detain the plaintiff's chattel; while the compurgators swore that they believed that he spoke the truth. It was an eminently unsatisfactory way of arriving at the merits of a claim and it is therefore not surprising to find that the policy of the law was in favor of its restriction rather than of its extension. Thus it was not permitted where the defendant was not a person of good character, where the king sued, where the defendant was the executor or administrator of the person alleged to have owed the debt, or in any actions other than those named, even though the cause of action were the same. No wager of law was allowed in *assumpsit*, even though the cause of action were a simple debt. This led to the general adoption of *assumpsit*—proceeding originally upon a fictitious averment of a promise by the defendant—as a means of recovering debts. Where a penalty was created by statute, it became a common form to insert a proviso that no wager of law was to be allowed in an action for the penalty. Wager of law was finally abolished by 3 and 4 Will. IV. c. 42. Another form of the judicial wager in use up to 1845 was the feigned issue by which questions arising in the course of Chancery proceedings were sent for trial by jury in a common law court. The plaintiff averred the laying of a wager of £5 [$24.30] with the defendant that a certain event was as he alleged; the defendant admitted the wager, but disputed the allegation; on this issue was joined. 8 and 9 Vict. c. 109 enabled such questions to be referred by the Chancery to the common law courts in a direct manner.

Substantive Law.—A wager may be defined as "a promise to pay money or transfer property upon the determination or ascertainment of an uncertain event" (Anson, *Law of Contract*, p. 171). At common law wagers were legally enforceable, subject to certain rules dictated by considerations of public policy, *e.g.*, that they did not lead to immorality or breach of the peace, or expose a third person to ridicule. Actions or wagers were not favored by the judges; and, though a judge could not refuse to try such an action, he could, and often did, postpone it until after the decision of more important cases. Parliament gradually intervened to confine the common law within narrower limits, both in commercial and non-commercial wagers, and both by general and temporary enactments. An example of the latter was 7 Anne c. 16, avoiding all wagers and securities relating to the then war with France. The earliest general enactment was 16 Car. II. c. 7, prohibiting the recovery of a sum exceeding £100 [$486] lost in games or pastimes, or betting on the sides or hands of the players, and avoiding securities for money so lost. 9 Anne c. 19 avoided securities for such wagers for any amount, even in the hands of *bona fide* holders for value without notice, and enabled the loser of £10 [$48.60] or upwards to sue for the money he had lost within three months. The hardship of the Act, as it affects securities in the hands of *bona fide* holders, was remedied by 5 and 6 Will. IV. c. 41, which enacted that such securities should be taken to be held for illegal consideration. Finally, 8 and 9 Vict. c. 109, § 18, enacted "that all contracts or agreements, whether by parole or in writing, by way of gaming or wagering shall be null and void; and that no suit shall be brought or maintained in any court of law or equity for recovering any sum of money or valuable thing alleged to be won upon any wager, or which shall have been deposited in the hands of any person to abide the event on which any wager shall have been made; provided always that this enactment shall not be deemed to apply to any subscription, or contribution, or agreement to subscribe or contribute, for or towards any plate, prize, or sum of money to be awarded to the winner or winners of any lawful game, sport, pastime, or exercise."

What is a lawful game depends upon numerous statutes from 33 Hen. VIII. c. 9 downwards, among which may be classed the Lottery Acts (see LOTTERIES). A curious exception is made in some of the statutes in favor of unlawful games if they are played in a royal palace. The mere making of a wager is not now illegal, as it was under the earlier statutes; it is simply unenforceable. The winner has no legal remedy against the loser or the stakeholder. The loser can recover his stake where it still remains in the stakeholder's hands or has been paid over to the winner after notice from the loser to the stakeholder not to pay it over. He cannot recover where it has been paid over to the winner without notice. The agent in a wagering contract may have legal rights against his principal, though the principal has none against the other party. Agreements between buyers and sellers of stocks and shares to pay or receive differences only (sometimes known as "time-bargains") are within 8 and 9 Vict. c. 109, but a broker employed to speculate on the understanding that only differences should be paid by his principal may recover indemnity against the principal. Employment of an agent to bet in his own name may imply an authority to pay the bet if lost, an authority that may become irrevocable after payment to the winner. Though wagers themselves are now void and not illegal, securities for wagers, by the combined effect of 5 and 6 Will. IV. c. 41 and 8 and 9 Vict. c. 109, are still either illegal (as a bet on the result of a game) or void (as a bet on the result of something other than a game, such as a contested election). This difference is important as affecting the question of burden of proof in actions on securities originally given for wagering purposes. Where the consideration is illegal, the plaintiff must show affirmatively that he gave value, but the mere absence of consideration throws on him no such duty. In commercial matters the most important examples are wagering policies of insurance, that is, policies made by persons having no insurable interest, and made void by statute (see INSURANCE). Sir John Barnard's Act, 7 Geo. II. c. 8 (called "An Act to prevent the infamous practice of stock-jobbing"), prohibited contracts for liberty to accept or refuse any public stocks or securities, and wagers relating to the stocks.

In Scotland the courts refuse to try actions on wagers, as being *sponsiones ludicræ*, unbecoming the dignity of the courts. 9 Anne c. 19 and 5 and 6 Will. IV. c. 41 extend to Scotland, but the weight of judicial opinion is that 8 and 9 Vict. c. 109 does not. In the United States the loser may, by the legislation of some States, recover his money if he sue within a limited time, as he might have done in England under 9 Anne c. 19.

Definition.

WAGES. Wages, although one of the most common and familiar terms in economic science, is at the same time one of the most difficult to define accurately. The natural definition is that wages is the "reward for labor," but then we are at once confronted with the difficulty so well stated by Adam Smith: "The greater part of people understand better what is meant by a quantity of a particular commodity than by a quantity of labor; the one is a plain palpable object, the other an abstract notion, which, though it can be made sufficiently intelligible, is not altogether so natural and obvious." If we regard wages as the reward for a quantity of labor, it is clear that to make the meaning precise we must give a precise meaning to this abstract notion of Adam Smith. From the point of view of the laborer the quantity of labor refers not so much to the work accomplished (*e.g.*, raising so many foot-pounds) as to "all the feelings of a disagreeable kind, all the bodily inconvenience or mental annoyance, connected with the employment of one's *thoughts* or muscles or both in a particular occupation" (J. S. Mill). But this analysis seems only to make the task of definition more difficult, for the class of laborers, in this wide sense of the term labor, would include the capitalist who racks his brains in making plans just as much as the navvy who digs with the sweat of his brow. Thus "profits," in the ordinary sense of the term, instead of being contrasted, would to a large extent be classified with wages, and in fact the wages of superintendence or of management is one of the recognized elements in the classical analysis of profits. It is, however, only when we refer to the list of "occupations" in any civilized country that we can really form an adequate idea of the variety of classes to which the term labor, as defined by Mill, may be extended. In the *General Report* of the census (1881) in England and Wales (published 1883) an analysis is given of the "unoccupied class." After deducting children and young persons under fifteen, persons over sixty-five years of age, who for the most part had been engaged in work of some kind previously, and those between the ages of fifteen and twenty, who might be considered as training for work, there remained 4,641,190 between the ages of twenty and sixty-five without specified occupation. But of these 4,458,908 were "women, of whom by far the greater part were married and engaged in the management of domestic life," and thus the number of males in the working period of life (20–65) of the "unoccupied" class was reduced to 182,282. Thus practically nearly the whole of the efficient male population of the country was engaged in some form of "labor" and in receipt of some form of "wages."

It may be granted that in certain economic inquiries it is extremely useful to bring out the points of resemblance between "workers" at the various stages of the social scale, and it is especially serviceable in showing that the opposition between "employer" and the "employed," and the "classes" and the "masses," is often exaggerated. At the same time, however, the differences, if not in kind at any rate in degree, are so great that if the analogy is carried very far it becomes misleading. Accordingly it seems natural to adopt as the preliminary definition of "wages" something equivalent to that of Prof. Walker in his work on the *Wages Question* (the best book on the subject as a whole), viz., "the reward of those who are employed in production with a view to the profit of their employers and are paid at stipulated rates." Even as thus restricted the "working or wage-earning classes" represent probably two-thirds of the population of the United Kingdom. It may be observed that by extending the meaning of production, as is now done by most economists, to include all kinds of labor, and by substituting benefit for profit, this definition will include all grades of wages.

Nominal and real wages.

Having thus limited the class of those who earn "wages," the next point is to consider the way in which the wages ought to be measured. The most obvious method is to take as the rate of *time-wages* the amount of *money* earned in a certain *time*, and as the rate of *task-wages* the amount of *money* obtained for a given amount of *work* of a given quality; and in many inquiries this rough mode of measurement is sufficient. But the introduction of money as the measure at once makes it necessary to assume that for purposes of comparison the value of the money to the wage-earners may be considered constant. This supposition, however, does not hold good even between different places in the same country at the same time, and still less with variations in time as well as place. To the laborers, however, the amount of money they obtain is only a means to an end, and accordingly economists have drawn a sharp distinction between *nominal* and *real* wages. "Labor, like commodities," says Adam Smith, "may be said to have a real and a nominal price. Its real price may be said to consist in the quantity of the necessaries and conveniences of life which are given for it; its nominal price in the quantity of money. The laborer is rich or poor, is well or ill rewarded, in proportion to the real not to the nominal price of his labor.

Variations in real wages.

Prof. Walker (*op. cit.*, p. 12 *sq.*) has given a full analysis of the principal elements which ought to be taken into account in estimating the *real* wages of labor. They may be classified as follows. (1) Variations in the purchasing power of money may be due in the first place to causes affecting the general level of prices in a country. Such, for instance, is a debasement of the coinage, of which a good example is furnished in English history in the reigns of Henry VIII. and Edward VI. Prof. Thorold Rogers has ascribed much of the degradation of labor which ensued to this fact; and Lord Macaulay has given a graphic account of the evils suffered by the laboring classes prior to the recoinage of 1696. The issues of inconvertible paper notes in excess have frequently caused a disturbance of real wages, and it is generally asserted that in this case wages as a rule do not rise so quickly as commodities. A general rise in prices due to great discoveries of the precious metals would, if nominal wages remained the same, of course cause a fall in real wages. There are, however, good grounds for supposing that the stimulus given to trade in this case would raise wages at least in proportion; and certainly the great gold discoveries in Australia and California raised wages in England, as is shown in Tooke's *History of Prices*, vol. v. p. 284. Similarly it is possible that a general fall in prices, owing to a relative scarcity of the precious metals, may lower the prices of commodities before it lowers the price of labor, in which case there is a rise in real wages. In the controversy as to the possible advantages of bimetallism this is one of the points most frequently discussed. It is impossible to say *a priori* whether a rise or fall in general prices, or a change in the value of money, will raise or lower real wages, since the result is effected principally by indirect influences. But, apart from these general movements in prices, we must, in order to find the real value of nominal wages, consider variations in local prices, and in making this estimate we must notice the principal items in the expenditure of the laborers. Much attention has been given recently by statisticians to this subject, with the view of finding a good "index number" for real wages. (2) Varieties in the form of payment require careful attention. Sometimes the payment is only partly in money, especially in agriculture in some places. In many parts of Scotland the laborers receive meal, peats, potatoes, etc. (3) Opportunities for extra earnings are sometimes of much importance, especially if we take as the wage-earning unit the family and not the individual. At the end of last century Arthur Young, in his celebrated tours, often calls attention to this fact. At the present time, in Northumberland and other counties a "hind" (*i.e.*, agricultural laborer) is more valued if he has a large working family, and the family earnings are relatively large. (4) Regularity of employment is always, especially in modern times, one of the most important points to be considered. Apart from such obvious causes of fluctuation as the nature of the employment, *e.g.*, in the case of fishermen, guides, etc., there are various social and industrial causes (for a particular and able investigation of which the reader may consult Prof. Foxwell's essay on the subject). Under the system of production on a large scale for foreign markets, with widely-extended division of labor, it seems impossible to adjust accurately the supply to the demand, and there are, in consequence, constant fluctuations in the employment of labor. A striking example, happily rare, is furnished by the cotton famine during the American civil war. (5) In forming a scientific conception of real wages we ought to take into account the longer or the shorter duration of the power to labor: the man whose employment is healthy and who lives more comfortably and longer at the same nominal rate of wages may be held to obtain a higher real wage than his less fortunate competitor. It is worth noting, in this respect, that in nearly every special industry there is a liability to some special form of disease: *e.g.*, lace-workers often suffer from diseases of the eyes, miners from diseases of the lungs, etc. (For further illustration the reader may consult the excellent works of Mr. Bevan on *Industrial Classes and Industrial Statistics*). Thus, in attempting to estimate real wages, we have to consider all the various discomforts involved in the "quantity of labor" as well as all the conveniences which the nominal wages will purchase and all the supplements in kind.

General rate of wages in any country at any time.

In a systematic treatment of the wages question it would be natural to examine next the causes which determine the general rate of wages in any country at any time. This is a problem to which economists have given much attention, and is one of great complexity. It is difficult, when we consider the immense variety of "occupations" in any civilized country and the constant changes which are taking place, even to form an adequate conception of the general rate of wages. At the census in 1881 in the United Kingdom, the commissioners found it necessary to make a small dictionary of the words by which different classes of workers described their callings, and without a special dictionary it would be impossible to classify such as the following: "blabber," "doctor-maker," "fluker," "egger," "lurer," "toother," etc. There are thousands of occupations of various kinds, and at first sight it may seem impossible to determine, in a manner sufficiently accurate for any useful purpose, an average or general rate of wages, especially if we attempt to take real and not merely nominal wages. At the same time, however, in estimating the progress of the working-classes, or in comparing their relative positions in different countries, it is necessary to use this conception of a general rate of wages in a practical manner. The difficulties presented are of the same kind as those met with in the determination of the value of money or the general level of prices, and may be overcome to some extent by the same methods. An "index number" may be formed by taking various kinds of labor as fair samples, and the nominal wages thus obtained may be corrected by a consideration of the elements in the real wages to which they correspond. Care must be taken, however, that the quantity and quality of labor taken at different times and places are the same, just as in the case of commodities similar precautions are necessary. Practically, for example, errors are constantly made by taking the rate of wages for a short time (say an hour), and then, without regard to regularity of employment, constructing the annual rate on this basis; and again, insufficient attention is paid to Adam Smith's pithy caution that "there may be more labor in an hour's hard work than in two hours' easy business." But, however difficult it may be to obtain an accurate measure of the general rate of wages for practical purposes, there can be no doubt as to the value and necessity of the conception in the theory of political economy. For, as soon as it is assumed that industrial competition is the principal economic force in the distribution of the wealth of a community, and this is in reality the fundamental assumption of modern economic science, a distinction must be drawn between the most general causes which affect all wages and the particular causes which lead to differences of wages in different employments. In other words, the actual rate of wages obtained in any particular occupation depends partly on causes affecting that group compared with others, and partly on the general conditions which determine the relations between labor, capital, and production over the whole area in which the industrial competition is effective.

Wages-fund theory.

Thus the theory of the wages question consists of two parts, or gives the answers to two questions: (1) What are the causes which determine the general rate of wages? (2) Why are wages in some occupations and at some times and places above or below this general rate?

With regard to the first question, Adam Smith, as in almost every important economic theory, gives an answer which combines two views which were subsequently differentiated into antagonism. "The produce of labor constitutes the natural recompense or wages of labor," is the opening sentence of his chapter on wages. But then he goes on to say that "this original state of things, in which the laborer enjoyed the whole produce of his own labor, could not last beyond the first introduction of the appropriation of land and the accumulation of stock." And he thus arrives at the conclusion that "the demand for those who live by wages, it is evident, cannot increase but in proportion to the increase of the *funds* which are *destined* to the payment of wages." This is the germ of the celebrated wages-fund theory which was carried to an extreme by J. S. Mill and others; and, although Mill abandoned the theory some time before his death, he was unable to eradicate it from his systematic treatise and to reduce it to its proper dimensions. It is important to observe that in the hands of Mill this theory was by no means, as was afterwards maintained by Prof. Cairnes, a mere statement of the problem to be solved. According to Cairnes (*Leading Principles of Political Economy*, bk. ii.), the wages-fund theory, as given in Mill's *Principles* (bk. ii. ch. xi. § 1), embraces the following statements: (1) the wages-fund is a general term used to express the aggregate of all wages at any given time in possession of the laboring population; (2) the average wage depends on the proportion of this fund to the number of people; (3) the amount of the fund is determined by the amount of general wealth applied to the direct purchase of labor. These propositions Cairnes easily reduces to mere verbal statements, and he then states that the real difficulty is to determine the causes which govern the demand and supply of labor. But the most superficial glance, as well as the most careful survey, will convince the reader of Mill's chapters on wages that he regarded the theory not as the statement but as the solution of the problem. For he applies it directly to the explanation of movements in wages, to the criticism of popular remedies for low wages, and to the discovery of what he considers to be legitimate and possible remedies. In fact, it was principally on account of the application of the theory to concrete facts that it aroused so much opposition, which would have been impossible if it had been a mere statement of the problem.

Analysis of the theory.

The wages-fund theory as a real attempt to solve the wages question may be resolved into three propositions, which are very different from the verbal truisms of Cairnes. (1) In any country at any time there is a determinate amount of capital unconditionally destined for the payment of labor. This is the wages-fund. (2) There is also a determinate number of laborers who must work independently of the rate of wages,—that is, whether the rate is high or low. (3) The wages-fund is distributed amongst the laborers solely by means of competition, masters competing with one another for labor, and laborers with one another for work, and thus the average rate of wages depends on the proportion between wage-capital and population. It follows then, according to this veiw, that wages can only rise either owing to an increase of capital or a diminution of population, and this accounts for the exaggerated importance attached by Mill to the Malthusian theory of population. It also follows from the theory that any restraint of competition in one direction can only cause a rise of wages by a corresponding fall in another quarter, and in this form it was the argument most frequently urged against the action of trade unions. It is worth noting, as showing the vital connection of the theory with Mill's principles, that it is practically the foundation of his propositions on capital in his first book, and is also the basis of the exposition in his fourth book of the effects of the progress of society on the condition of the working-classes.

It has often been remarked that, in economics as in other sciences, what eventually assumes the form of the development of or supplement to an old theory at first appears as if in direct antagonism to it, and there is reason to think that the criticism of the wages-fund theory was carried to an extreme, and that the essential elements of truth which it contains were overlooked. In many respects the theory may be regarded as a good first approximation to the complete solution of the problem. The causes which it emphasizes too exclusively are after all *veræ causæ*, and must always be taken into account. There can be no doubt, for example, that under certain conditions a rapid increase in the laboring population may cause wages to fall, just as a rapid decline may make them rise. The most striking example of a great improvement in the condition of the laboring classes in English economic history is found immediately after the occurrence of the Black Death in the middle of the 14th century. The sudden and extensive thinning of the ranks of labor was manifestly the principal cause of the great improvement in the condition of the survivors.

Apparent truth of it.

Again, as regards the amount of capital competing for labor, the reality of the cause admits of no dispute, at any rate in any modern society. The force of this element is perhaps best seen by taking a particular case and assuming that the general wages-fund of the country is divided into a number of smaller wages-funds. Take, for example, the wages of domestic servants when the payment of wages is made simply for the service rendered. We may fairly assume that the richer classes of the community practically put aside so much of their revenue for the payment of the wages of their servants. The aggregate of these sums is the domestic wages-fund. Now, if owing to any cause the amount available for this purpose falls off, whilst the number of those seeking that class of employment remains the same, the natural result would be a fall in wages. It may of course happen in this as in other cases that the result is not so much a direct fall in the rate of wages as a diminution of employment—but even in this case, if people employ fewer servants, they must do more work. Again, if we were to seek for the reason why the wages of governesses are so low, the essence of the answer would be found in the excessive supply of that kind of labor compared with the funds destined for its support. And similarly through the whole range of employments in which the labor is employed in perishable services and not in material products, the wages-fund theory brings into prominence the principal causes governing the rate of wages, namely, the number of people competing, the amount of the fund competed for, and the effectiveness of the competition. This view also is in harmony with the general principles of demand and supply. If we regard labor as a commodity and wages as the price paid for it, then we may say that the price will be so adjusted that the quantity demanded will be made equal to the quantity offered at that price,—the agency by which the equation is reached being competition.

Apparent failure of it.

But when we turn to other facts for the verification of the theory we easily discover apparent if not real contradictions. The case of Ireland after the potato famine affords an instance of a rapidly declining population without any corresponding rise in wages, whilst in new countries we often find a very rapid increase of population accompanied by an increase in wages. In a similar manner we find that the capital of a country may increase rapidly without wages rising in proportion—as, for example, seems to have been the case in England after the great mechanical improvements at the end of last century up to the repeal of the Corn Laws—whilst in new countries where wages are the highest there are generally complaints of the scarcity of capital. But perhaps the most striking conflict of the theory with facts is found in the periodical inflations and depressions of trade. After a commercial crisis, when the shock is over and the necessary liquidation has taken place, we generally find that there is a period during which there is a glut of capital and yet wages are low. The abundance of capital is shown by the low rate of interest and the difficulty of obtaining renumerative investments. Accordingly this apparent failure of the theory, at least partially, makes it necessary to examine the propositions into which it was resolved more carefully, in order to discover, in the classical economic phraseology, the "disturbing causes." As regards the first of these propositions—that there is always a certain amount of capital destined for the employment of labor—it is plain that this destination is not really unconditional. In a modern society whether or not a capitalist will supply capital to labor depends on the rate of profit expected, and this again depends proximately on the course of prices. But the theory as stated can only consider profits and prices as acting in an indirect round-about manner upon wages. If profits are high then more capital can be accumulated and there is a larger wages-fund, and if prices are high there may be some stimulus to trade but the effect on real wages is considered to be very small. In fact Mill writes it down as a popular delusion that high prices make high wages. And if the high prices are due purely to currency causes the criticism is in the main correct, and in some cases, as was shown above, high prices may mean low real wages. If, however, we turn to the great classes of employments in which the labor is embodied in a material product, we find on examination that wages vary with prices in a real and not merely in an illusory sense. Suppose, for example, that, owing to a great increase in the foreign demand for our produce, a rise in prices takes place, there will be a corresponding rise in nominal wages, and in all probability a rise in real wages. Such was undoubtedly the case in Great Britain on the conclusion of the Franco-German war.

On the other hand, if prices fall and profits are low, there will so far be a tendency to contract the employment of labor. At the same time, however, to some extent the capital is applied unconditionally,—in other words, without obtaining what is considered adequate remuneration, or even at a positive loss. The existence of a certain amount of fixed capital practically implies the constant employment of a certain amount of labor.

Nor is the second proposition perfectly true, namely, that there is always a certain amount of laborers, who must work independently of the rate of wages. For the returns of pauperism and other statistics show that there is always a proportion of "floating" labor sometimes employed and sometimes not. Again, although, as Adam Smith says, man is of all luggage the most difficult to be transported, still labor as well as capital may be attracted to foreign fields. The constant succession of strikes resorted to in order to prevent a fall in wages shows that in practice the laborers do not at once accept the "natural" market rate. Still, on the whole, this second proposition is a much more adequate expression of the truth than the first; for labor cannot afford to lie idle or to emigrate so easily as capital.

The third proposition, that the wages-fund is distributed solely by competition is also found to conflict with facts. Competition may be held to imply in its positive meaning that every individual strives to attain his own economic interests regardless of the interests of others. But in some cases this end may be attained most effectively by means of combination, as, for example, when a number of people combine to create a practical monopoly. Again, the end may be attained by leaving the control to Government, or by obeying the unwritten rules of long-established custom. But these methods of satisfying the economic instincts are opposed to competition in the usual sense of the term, and certainly as used in reference to labor. Thus on the negative side competition implies that the economic interests of the persons concerned are attained neither by combination, nor by law, nor by custom. Again, it is also assumed, in making competition the principal distributing force of the national income, that every person knows what his real interests are, and that there is perfect mobility of labor both from employment to employment and from place to place. Without these assumptions the wages-fund would not be evenly distributed according to the quantity of labor. It is, however, obvious that, even in the present industrial system, competition is modified considerably by these disturbing agencies; and in fact the tendency seems to be more and more for combinations of masters on one side and of men on the other to take the place of the competition of individuals.

Wages paid from the produce of labor.

The attempted verification of the wages-fund theory leads to so many important modifications that it is not surprising to find that in recent times the tendency has been to reject it altogether. And thus we arrive at the development of Adam Smith's introductory statement, namely, that the produce of labor constitutes the natural recompense or wages of labor. The most important omission of the wages-fund theory is that it fails to take account of the quantity produced and of the price obtained for the product. If we bring in these elements, we find that there are several other causes to be considered besides capital, population and competition. There are, for example, the various factors in the efficiency of labor and capital, in the organization of industry, and in the general condition of trade. To some extent these elements may be introduced into the old theory, but in reality the point of view is quite different. This is made abundantly clear by considering Mill's treatment of the remedies for low wages. His main contention is that population must be rigidly restrained in order that the average rate of wages may be kept up. But, as several American economists have pointed out, in new countries especially, every increase in the number of laborers may be accompanied by a more than proportionate increase in the produce and thus in the wages of labor. Again the older view was that capital must be first accumulated in order afterwards to be divided up into wages, as if apparently agriculture was the normal type of industry, and the workers must have a store to live on until the new crop was grown and secured. But the "produce" theory of wages considers that wages are paid continuously out of a continuous product, although in some cases they may be advanced out of capital or accumulated stores. According to this view wages are paid out of the annual produce of the land, capital, and labor, and not out of the savings of previous years. There is a danger, however, of pushing this theory to an untenable extreme, and overlooking altogether the function of capital in determining wages; and the true solution seems to be found in a combination of the "produce" theory with the "fund" theory.

An industrial society may be regarded, in the first place, as a great productive machine turning out a vast variety of products for the consumption of the members of the society. The distribution of these products, so far as it is not modified by other social and moral conditions, depends upon the principle of "reciprocal demand." In a preliminary rough classification we may make three groups—the owners of land and natural agents, the owners of capital or reserved products and instruments, and the owners of labor. To obtain the produce requisite even for the necessary wants of the community a combination of these three groups must take place, and the relative reward obtained by each will vary in general according to the demands of the others for its services. Thus, if capital, both fixed and circulating, is scanty, whilst labor and land are both abundant, the reward of capital will be high relatively to rent and wages. This is well illustrated in the high rate of profits obtained in early societies. According to this view of the question the aggregate amount paid in wages depends partly on the general productiveness of all the productive agents and partly on the relative power of the laborers as compared with the owners of land and capital (the amount taken by Government and individuals for taxes, charity, etc., being omitted). Under a system of perfect industrial competition the general rate of wages would be so adjusted that the demand for labor would be just equal to the supply at that rate.

Relative wages.

If all labor and capital were perfectly uniform it would not be necessary to carry the analysis further, but as a matter of fact, instead of two great groups of laborers and capitalists, we have a multitude of subdivisions all under the influence of reciprocal demand. Every sub-group tries to obtain as much as possible of the general product, which is practically always measured in money. The determination of relative wages depends on the constitution of these groups and their relations to one another. Under any given social conditions there must be differences of wages in different employments, which may be regarded as permanent until some change occurs in the conditions; in other words, certain differences of wages are stable or normal, whilst others depend simply on temporary fluctuations in demand and supply. A celebrated chapter in the *Wealth of Nations* (bk. i. ch. x.) is still the best basis for the investigation of these normal differences,—which, as stated above, is the *second* principal problem of the wages question. First of all, a broad distinction may be drawn between the natural and artificial causes of difference, or, in Adam Smith's phraseology, between those due to the nature of the employments and those due to the policy of Europe. In the former division we have (1) the agreeableness or disagreeableness of the employment, illustrated by two classical examples—"honor makes a great part of the reward of all honorable professions," and "the most detestable of all employments—that of public executioner—is, in proportion to the work done, better paid than any common trade whatever." There is, however, much truth in Mill's criticism, that in many cases the worst paid of all employments are at the same time the most disagreeable, simply because those engaged in them have practically no other choice. (2) The easiness and cheapness, or the reverse, of learning the business. This factor operates in two ways. A difficult business implies to some extent peculiar natural qualifications, and it also involves the command of a certain amount of capital to subsist on during the process of learning, and thus in both respects the natural supply of labor is limited. (3) The constancy or inconstancy in the employment,—a point

Natural causes of difference.

already noticed under real wages. (4) The great or small trust reposed in the workmen, an important consideration in all the higher grades of labor, *e.g.*, bankers, lawyers, doctors, etc. (5) The chance of success or the reverse. Here it is to be observed that, owing to the hopefulness of human nature and its influence on the gambling spirit, the chance of success is generally overestimated, and therefore that the wages in employments where the chance of success is really small are lower than they ought to be. The most striking instance is furnished by the labor in gold mines, diamond fields, and the like, and the same cause also operates in many of the professions.

All these causes of differences of wages in different employments may be explained by showing the way in which they operate on the demand and supply of labor in the particular group. If the "net advantages," to adopt Prof. Marshall's phraseology, of any group are relatively high, then labor will be directly attracted to that group, and the children born in it will be brought up to the same occupation, and thus in both ways the supply of labor will be increased. But the "net advantages" embrace the conditions just enumerated. Again, if the other members of the community require certain forms of labor to a greater extent, there is an increase in the demand and a rise in their price.

Artificial causes of difference.

In addition to these so-called natural causes of difference, there are those arising from law, custom, or other so-called artificial causes. They may be classified under four headings. (1) Certain causes artificially restrain industrial competition by limiting the number of any particular group. Up to the close of last century, and in many instances to a much later date, the regulations of guilds and corporations limited the numbers in each trade (*cf.* Brentano, *Guilds and Trade Unions*). This they did by making a long apprenticeship compulsory on those wishing to learn the craft, by restricting the number of apprentices to be taken by any master, by exacting certain qualifications as to birth or wealth, by imposing heavy entrance fees, either in money or in the shape of a useless but expensive masterpiece. Some of these regulations were originally passed in the interests of the general public and of those employed in the craft, but in the course of time their effect was, as is stated by Adam Smith, simply to unduly restrain competition. The history of the craft-guilds is full of instructive examples of the principles governing wages. No doubt the regulations tended to raise wages above the natural rate, but as a natural consequence industry migrated to places where the oppressive regulations did not exist. In the time of the Tudors the decay of many towns during a period of rapid national progress was largely due to those "fraternities in evil," as Bacon called the guilds. At present one of the best examples of the survival of this species of artificial restriction is the limitation of the number of teachers qualifying for degrees in certain universities. (2) In some employments, however, law and custom tend unduly to increase the amount of competition. This was to a great extent the case in the church and the scholastic professions owing to the large amount of charitable education. Adam Smith points out that even in his day a curate was "passing rich on forty pounds [$194.40] a year," whilst many only obtained £20 [$97.20],—below the wages earned by a journeyman shoemaker. In the same way state-aided education of a commercial and technical kind may result in lowering the rates (relatively) of the educated business classes. It is said that one reason why the Germans replace Englishmen in many branches is that, having obtained their education at a low rate, there are more of them qualified, and consequently they accept lower wages. The customary idea that the position of a clerk is more genteel than that of an artisan accounts largely for the excessive competition in the former class, especially now that education is practically universal. (3) In some cases law and custom may impede or promote the circulation of labor. At the time Adam Smith wrote the laws of settlement were still in full operation. "There is not a man of forty who has not felt most cruelly oppressed by this ill-contrived law of settlement." Differences in wages in different parts of the same country and in different occupations are still largely due to impediments in the way of the movement of labor, which might be removed or lessened by the Government making provisions for migration or emigration. (4) On many occasions in the past the law often directly interfered to regulate wages. The Statute of Laborers, passed immediately after the Black Death, was an attempt in this direction, but it appears to have failed, according to the investigations of Prof. Thorold Rogers. The same writer, however, ascribes to the celebrated Statute of Apprentices (5th of Elizabeth) the degradation of the English laborer for nearly three centuries (*Agriculture and Prices*, vol. v.). This, he asserts, was due to the wages being fixed by the justices of the peace. It is, however, worth noting that Brentano, who is equally sympathetic with the claims of labor, asserts that so long as this statute was actually enforced, or the customs founded upon it were observed, the condition of the laborers was prosperous, and that the degradation only began when the statute fell into disuse (*Origin of Guilds and Trade Unions*).

State regulation of wages.

It is impossible in the limits of this article to discuss this particular case, but something must be said as to the power of the state to regulate wages. As far as any direct regulation is concerned, it seems to be only possible within narrow limits. The state might of course institute certain complex sliding-scales for different classes of labor and make them compulsory, but this would rather be an official declaration of the natural market rate than a direct regulation. Any rate which the state of trade and prices would not bear could not be enforced: masters could not be compelled to work at a loss or to keep their capital employed when it might be more advantageously transferred to another place or occupation. Thus the legal rate could not exceed to any considerable extent the market rate. Nor on the other hand, could a lower rate in general be enforced, especially when the laborers have the right of combination and possess powerful organizations. And even apart from this the competition of capitalists for labor would tend to raise wages above the legal rate, and evasion would be extremely easy.

Poor relief in aid of wages.

The best illustration of the failure to raise the rate of wages directly by authority is found in the English poor law system between 1796 and 1834. "In the former year (1796) the decisively fatal step of legalizing out-relief to the able-bodied and *in aid of wages*, was taken," and "in February, 1834, was published perhaps the most remarkable and startling document to be found in the whole range of English, perhaps indeed of all social, history" (Fowle's *Poor Law*). The essence of the system was in the justices determining a natural rate of wages, regard being paid to the price of necessaries and the size of the laborer's family, and an amount was given from the rates sufficient to make up the wages received to this natural level. The method of administration was certainly bad, but the best administration possible could only have kept the system in existence a few years longer. In one parish the poor-rate had swallowed up the whole value of the land, which was going out of cultivation, a fact which has an obvious bearing on land nationalization as a remedy for low wages. The laborers became careless, inefficient and improvident. Those who were in regular receipt of relief were often better off (in money) than independent laborers. But the most important consequence was that the real wages obtained were, in spite of the relief, lower than otherwise they would have been, and a striking proof was given that wages are paid out of the produce of labor. The *Report of the*

Poor Law Commissioners (1834) states emphatically (p. 48) that "the severest sufferers are those for whose benefit the system is supposed to have been introduced and to be perpetuated, the laborers and their families." The independent laborers suffered directly through the unfair competition of the pauper labor, but, as one of the sub-reporters stated, in every district the general condition of the independent laborer was strikingly distinguishable from that of the pauper and superior to it, though the independent laborers were commonly maintained upon less money.[1]

Factory legislation.

But, although the direct intervention of the state, with the view of raising the nominal rates of wages, is, according to theory and experience, worse than useless, still, when we consider real wages in the evident sense of the term, there seems to be an almost indefinite scope for state interference. The effect of the Factory Acts and similar legislation has been undoubtedly to raise the real wages of the working-classes as a whole, although at first the same arguments were used in opposition to these proposals as in the case of direct relief from the poor-rates. But there is a vital difference in the two cases, because in the former the tendency is to increase whilst in the latter it is to diminish the energy and self-reliance of the workers. An excellent summary of the results of this species of industrial legislation is given by Mr. John Morley (*Life of Cobden*, vol. i. p. 303):

> "We have to-day a complete, minute, and voluminous code for the protection of labor: buildings must be kept pure of effluvia; dangerous machinery must be fixed; children and young persons must not clean it while in motion; their hours are not only limited but fixed; continuous employment must not exceed a given number of hours, varying with the trade but prescribed by the law in given cases; a statutable number of holidays is imposed; the children must go to school, and the employer must have every week a certificate to that effect; if an accident happens notice must be sent to the proper authorities; special provisions are made for bakehouses, for lace-making, for collieries, and for a whole schedule of other special callings; for the due enforcement and vigilant supervision of this immense host of minute prescriptions there is an immense host of inspectors, certifying surgeons, and other authorities whose business it is to 'speed and post o'er land and ocean' on sullen guardianship of every kind of labor, from that of the woman who plaits straw at her cottage door to the miner who descends into the bowels of the earth and the seaman who conveys the fruits and materials of universal industry to and fro between the remotest parts of the globe."

The analysis previously given of real wages shows that logically all these improvements in the conditions of labor, by diminishing the "quantity of labor" involved in work, are equivalent to a real rise in wages. Experience has also shown that the state may advantageously interfere in regulating the method of paying wages. A curious poem, written about the time of Edward IV., on England's commercial policy (*Political Songs and Poems*, Rolls Series, vol. ii. p. 282), shows that even in the 15th century the "truck" system was in full operation, to the disadvantage of the laborers. The cloth-makers, in particular, compelled the workers to take half of their wages in merchandise which they estimated at higher than its real value. The writer proposes that the "wyrk folk be paid in good moné," and that a sufficient ordinance be passed for the purpose, and a law to this effect was enacted in the 4th year of Edward IV. At the present day the Truck Act (1st and 2d William IV.) is in full operation, and has quite recently been extended. Again, the legislation directed against the adulteration of all kinds of goods, which also finds its prototypes in the Middle Ages, is in its effects equivalent to a rise in real wages.[2]

Trade unions and wages.

The power of trade unions in regulating wages is in most respects analogous in principle to that of legislation just noticed. Nominal wages can only be affected within comparatively narrow limits, depending on the condition of trade and the state of prices, whilst in many cases a rise in the rate in some trades or places can only be accomplished by a corresponding depression elsewhere. At the same time, however, it can hardly be questioned that through the unions nominal wages have on the whole risen at the expense of profits,—that is to say, that combinations of laborers can make better bargains than individuals. But the debatable margin which may make either extra profits or extra wages is itself small (*cf.* Atkinson on the *Distribution of Products*), and at present the principal direct effect of trade unions is to make wages fluctuate with prices, a rise at one time being compensated by a fall at another. The unions can, however, look after the interests of their members in many ways which improve their general condition or raise the real rate of wages, and when nominal wages have attained a natural maximum, and some method of arbitration or sliding-scale is in force, this indirect action seems the principal function of trade unions. The effects of industrial partnership (*cf.* Sedley Taylor's *Profit Sharing*) and of productive co-operation (*cf.* Holyoake's *History of Co-operation*) are at present small in amount (compared with the total industry of any country) though excellent in kind, and there seem to be no signs of the decay of the *entrepreneur* system.

Effects of machinery on wages.

The industrial revolution which took place about the end of last century, involving radical changes in production, destroyed the old relations between capital and labor, and perhaps the most interesting part of the history of wages is that covered by the present century. For fifty years after the introduction of production on a large scale, the condition of the working-classes was on the whole deplorable, but during the last fifty years great progress has been made. The principal results may be summed up under the effects of machinery on wages,—taking both words in their widest sense. Machinery affects the condition of the working-classes in many ways. The most obvious mode is the direct substitution of machinery for labor. It is clear that any sudden and extensive adoption of labor-saving machinery may, by throwing the laborers out of employment, lower the rate of wages, and it is easy to understand how riots arose repeatedly owing to this cause. But as a rule the effect of labor-saving machinery in diminishing employment has been greatly exaggerated, because two important practical considerations have been overlooked. In the first place any radical change made in the methods of production will be only gradually and continuously adopted throughout the industrial world; and in the second place these radical changes, these discontinuous leaps, tend to give place to advances by small *increments* of *invention*. We have an instance of a great radical change in the steam-engine. Watt's patent for "a method of lessening" the consumption of steam and fuel in fire-engines was published on January 5, 1769, and it may be said that the movement of substituting steam as a motive power is not yet over. Every day we hear of steam being extended to some new employment and to some out-of-the-way district. The history of the power-loom again shows that the adoption of an invention is comparatively slow. In 1813 there were not more than 2400 power-looms at work in England. In 1820 they increased to 14,150. In 1853 there were 100,000, but the curious thing is that during this time the number of hand-looms had actually *increased* to some extent (George R. Porter's *Progress of the Nation*, p. 186). The power-loom also illustrates the gradual continuous growth of improvements. This is clearly shown by Porter. A very good hand-weaver, twenty-five or thirty years of age, could weave two pieces of shirting per week. In 1823 a steam-loom weaver, about fifteen years of age, attending two looms, could weave nine similar pieces in a week. In 1826 a steam-loom weaver, about fifteen, attending to four looms, could weave twelve similar pieces a week. In 1833 a steam-loom weaver, from fifteen to twenty, assisted by a girl of twelve, attending to four looms, could weave eighteen pieces. This is only one example, for, as Porter remarks, it would fill many large volumes to describe the numerous inventions which during the present century imparted facility to manufacturing processes, and in every case we find a continuity in the improvements. This twofold progressive character of invention operates in favor of the laborer—in the first place, because in most cases the increased cheapness of the commodity consequent on the use of machinery causes a corresponding extension of the market and the amount produced, and thus there may be no actual diminution of employment even temporarily; and secondly, if the improvement takes place slowly, there is time for the absorption of the redundant labor in other employments. It is quite clear that on balance the great increase in population in this century has been largely caused, or rather rendered possible, by the increased use of labor-saving machinery. The way in which the working-classes were at first injured by the adoption of machinery was not so much by a diminution in the number of hands required as by a change in the nature of the employment. Skilled labor of a certain kind lost its peculiar value, and children and women were able to do work formerly only done by men. But the principal evils resulted from the wretched conditions under which, before the factory legislation, the work was performed; and there is good reason to believe that a deterioration of the type of laborer, both moral and physical, was effected. It is, however, a mistake to suppose that on the whole the use of machinery tends to dispense with skill. On the contrary, everything goes to prove that under the present system of production on a large scale there is on the whole far more skill required than formerly,—a fact which has been well brought out by Mr. Giffen in his essay on the progress of the working-classes (*Essays on Finance*, vol. ii. p. 365). The two lowest classes of labor, which constituted each about one-third of the whole manual-labor class of the United Kingdom fifty years ago, now constitute only one-eighth each, and the remaining highest-paid class, which was only one-third fifty years ago, is now three-fourths of the whole. Taking this fact into consideration, it is easy to understand the estimate that the money wages of labor have on the whole risen 100 per cent. during this period. There seems every reason to believe that this rise in real wages will continue with every extension of the power of man over nature. For, taking the most general view of the subject, the more there is produced or acquired in exchange from other countries, so much more is there to consume. But this very improvement in the production and acquisition of wealth facilitates the creation of new capital, and increases the rate of accumulation, and thus there is a greater intensity in the demand of capital for labor, and the rate of profits falls whilst the rate of wages rises.[1]

Progress of the working classes.

Tendency of profits to fall and wages to rise.

(J. S. N†.)

Law Relating to Wages.

The legislature has often dealt with wages in a manner which modern political economy would not endorse. The amount was fixed by the Statute of Laborers in 1349, and by many succeeding statutes (see Labor). The policy of these Acts is now obsolete, although the British parliament has never gone as far as the constitution of Louisiana, and expressly provided that no law is to fix the price of manual labor. To conspire to effect an alteration in wages is now no longer an offence. It was formerly punished very severely both at common law and under the provisions of various statutes, especially 2 and 3 Edw. VI. c. 15. Existing legislation on the subject of wages deals with the mode of their payment and recovery, and their protection from attachment and from the bankruptcy laws. They must (except in the case of farm servants) be paid in money, and the payment must not be made in a public house (see Payment). The recovery of wages by Seamen (*q.v.*) is the subject of special legislation. In other cases statutory authority is given to county courts and courts of summary jurisdiction to deal with claims for wages. See especially the Employers and Workmen Act, 1875. The County Courts Acts enable an infant to sue in a county court for wages not exceeding £50 [$243] as though he were of age. Wages are as a rule privileged debts (see Privilege). By 33 and 34 Vict. c. 30 the wages of a servant, laborer, or workman cannot be attached by order of a court of record or inferior court. In Scotland wages are exempt from arrestment on process under the Small Debt Acts and in any case up to 20s. [$4.86] a week by 8 and 9 Vict. c. 39 and 33 and 34 Vict. c. 63. The English Bankruptcy Act, 1883, gives priority in the distribution of a bankrupt's estate to wages of clerks, servants, laborers, and workmen up to the extent of £50 [$243]. The Scottish Bankruptcy Act, 1856 (as amended in 1875), is in similar terms.

WAGNER, Rudolph (1805–1864), anatomist and physiologist, was born in June, 1805, at Baireuth, where his father was a professor in the gymnasium. He began the study of medicine at Erlangen in 1820, and finished his curriculum in 1826 at Würzburg, where he had attached himself mostly to Schönlein in medicine and to Heusinger in comparative anatomy. Aided by a public *stipendium*, he spent a year or more studying in the Jardin des Plantes, under the friendly eye of Cuvier, and in making zoological discoveries at Cagliari and other places on the Mediterranean. On his return he set up in medical practice at Augsburg, whither his father had been transferred: but in a few months he found an opening for an academical career, on being appointed prosector at Erlangen. In 1832 he became full professor of zoology and comparative anatomy there, and held that office until 1840, when he was called to succeed Blumenbach at Göttingen. At the Hanoverian university he remained till his death in 1864, being much occupied with administrative work as pro-rector for a number of years, and for nearly the whole of his residence troubled by ill-health (hereditary phthisis). In 1860 he gave over the physiological part of his teaching to a new chair, retaining the zoological, with which his career had begun. While at Frankfurt, on his way to examine the Neanderthal skull at Bonn, he was struck with paralysis, and died at Göttingen a few months later (May, 1864) in his 59th year.

Wagner's activity as a writer and worker was enormous, and his range extensive, most of his hard work having been done at Erlangen while his health was good. His graduation thesis was on the ambitious subject of "the historical development of epidemic and contagious diseases all over the world, with the laws of their diffusion," which showed the influence of Schönlein. His first treatise was *Die Naturgeschichte des Menschen* (in 2 vols., Kempten, 1831). Frequent journeys to the Mediterranean, the Adriatic, and the North Sea gave him abundant materials for research on invertebrate anatomy and physiology, which he communicated first to the Munich academy of sciences, and republished in his *Beiträge zur vergleichenden Physiologie des Blutes* (Leipsic, 1832–33, with additions in 1838). In 1834–35 he brought out a text-book on the subject of his chair (*Lehrbuch der Vergleichenden Anatomie*, Leipsic), which recommended itself to students by its clear and concise style. A new edition of it appeared in 1843 under the title of *Lehrbuch der Zootomie*, of which only the vertebrate section was corrected by himself. The precision of his earlier work is evidenced by his *Micrometric Measurements of the Elementary Parts of Man and Animals* (Leipsic, 1834). His zoological labors may be said to conclude with the atlas *Icones Zootomicæ* (Leipsic, 1841). In 1835 he communicated to the Munich academy of sciences his researches on the physiology of generation and development, including the famous discovery of the germinal vesicle of the human ovum. These were republished under the title *Prodromus Historiæ*

Generationis Hominus atque Animalium (Leipsic, 1836). As in zoology, his original researches in physiology were followed by a students' text-book, *Lehrbuch der speciellen Physiologie* (Leipsic, 1838), which soon reached a third edition, and was translated into French and English. This was supplemented by an atlas, *Icones Physiologicæ* (Leipsic, 1839). To the same period belongs a very interesting but now little known work on medicine proper, of a historical and synthetic scope, *Grundriss der Encyklopädie und Methodologie der medicinischen Wissenschaften nach geschichtlicher Ansicht* (Erlangen, 1838), which was translated into Danish. About the same time he worked along with Will at a translation of Prichard's *Natural History of Man*, and edited various writings of Sömmering, with a biography of that anatomist (1844), which he himself fancied most of all his writings. In 1843, after his removal to Göttingen, he began his great *Handwörterbuch der Physiologie, mit Rücksicht auf physiologische Pathologie*, and brought out the fifth (supplementary) volume in 1852; the only contributions of his own in it were on the sympathetic nerve, nerve-ganglia, and nerve-endings, and he modestly disclaims all merit except as being the organizer. While resident in Italy for his health from 1845 to 1847, he occupied himself with researches on the electrical organ of the torpedo and on nervous organization generally; these he published in 1853–54 (*Neurologische untersuchungen*, Göttingen), and therewith his physiological period may be said to end. His next period was stormy and controversial. He entered the lists boldly against the materialism of "Stoff und Kraft," and avowed himself a Christian believer, whereupon he lost the countenance of a number of his old friends and pupils, and was unfeelingly told that he was suffering from an "atrophy of the brain." His quarrel with the materialists began with his oration at the Göttingen meeting of the Naturforscher-Versammlung in 1854 on "Menschenschöpfung und Seelensubstanz." This was followed by a series of "Physiological Letters" in the *Allgemeine Zeitung*, by an essay on "Glauben und Wissen," and by the most important piece of this series, "Der Kampf um die Seele" (Göttingen, 1857). Having come to the consideration of these philosophical problems late in life, he was at some disadvantage; but he endeavored to join as he best could in the current of contemporary German thought. He had an exact knowledge of classical German writings, more especially of Goethe's, and of the literature connected with him. In what may be called his fourth and last period, Wagner became anthropologist and archæologist, occupied himself with the cabinet of skulls in the Göttingen museum collected by Blumenbach and with the excavation of prehistoric remains, corresponded actively with the anthropological societies of Paris and London, and organized, in co-operation with the veteran Von Baer, a successful congress of anthropologists at Göttingen in 1861. His last writings were memoirs on the convolutions of the human brain, on the weight of brains, and on the brains of idiots (1860–62).

See memoir by his eldest son in the *Göttinger gelehrte Anzeigen*, "Nachrichten" for 1864.

WAGNER, Wilhelm Richard (1813–1883), dramatic composer and reformer of the musical drama, was born at Leipsic on May 22, 1813. In 1822 he was sent to the Kreuzschule at Dresden, where he did so well that four years later, he translated the first 12 books of the *Odyssey* for amusement. In 1828 he was removed to the Nicolaischule at Leipsic, where he was less successful. His first music-master was Gottlieb Müller, who thought him selfwilled and eccentric; and his first important composition was an "Overture in b♭," performed at the Leipsic theatre in 1830. In that year he matriculated at the university, and took lessons in composition from Theodor Weinlig, cantor at the Thomasschule. His "First Symphony" was performed at the Gewandhaus concerts in 1833, and in the following year he was appointed conductor of the opera at Magdeburg. The post was an unprofitable one, and Wagner's life at this period was very unsettled. He had composed an opera called *Die Feen*, adapted from Gozzi's *La Donna Serpente*, and another, *Das Liebesverbot*, founded on Shakespeare's *Measure for Measure*, but these were never performed, and for some considerable time the young composer found it difficult to obtain a hearing.

In 1836 Wagner married Fräulein Wilhelmina Planer, an actress at the theatre at Königsberg. He had accepted an engagement there as conductor, but, the lessee becoming bankrupt, the scheme was abandoned in favor of a better appointment at Riga. Accepting this, he remained actively employed until 1839, when he made his first visit to Paris, taking with him an unfinished opera, for which he had himself prepared a libretto, upon the lines of Lord Lytton's novel *Rienzi*. The venture proved a most unfortunate one. Wagner was unsuccessful in all his attempts to achieve popularity, and *Rienzi*, destined for the Grand Opéra, was relentlessly rejected. He completed it, however, and in 1842 it was produced at the court theatre in Dresden, where, with Madame Schroeder Devrient and Herr Tichatschek in the principal parts, it achieved an immense success, and undoubtedly laid the foundation of the great composer's fame.

Though, in completing *Rienzi*, Wagner had put forth all the strength he then possessed, that work was far from representing his preconceived ideal. This he now endeavored to embody in *Der Fliegende Holländer*, for which, as before, he composed both the libretto and the music. In this fine work we find the first sign of his determination to sacrifice all considerations of traditional form and symmetrical construction to the dramatic exigencies of the story. It is true, this great principle was but very faintly announced in the new work, and in an evidently tentative form; but the success of the experiment was incontestable, though it took some time to convince the world of the fact. The piece was warmly received at Dresden, January 2, 1843; but its success was by no means equal to that of *Rienzi*. Spohr, however, promptly discovered its merits, and produced it at Cassell some months later with very favorable results.

Wagner was now fairly launched upon his arduous career. On February 2, 1843, he was formally installed as hofkapellmeister at the Dresden theatre, and he celebrated the event by at once beginning the composition of a new opera. For the subject of this he selected the legend of Tannhäuser, collecting his materials from the ancient "Tannhäuser-Lieb,"[1] the *Volksbuch*, Tieck's poetical *Erzählung*, Hoffmann's story of *Der Sängerkrieg*, and the mediæval poem on *Der Wartburgkrieg*. This last-named legend introduces the incidental poem of "Loherangrin," and led to the study of Wolfram von Eschenbach's *Parzival und Titurel*, with strange effect upon Wagner's subsequent inspirations. But for the present he confined himself to the subject in hand; and on October 19, 1845, he produced his *Tannhäuser*, with Madame Schroeder Devrient, Fräulein Johanna Wagner,[2] Herr Tichatschek, and Herr Mitterwurzer in the principal parts. Notwithstanding this powerful cast, the success of the new work was not brilliant, for it carried still farther the principles embodied in *Der Fliegende Holländer*, and these principles were not yet understood either by the public or the critics. But Wagner boldly fought for them, and would probably have gained the victory much sooner than he did had he not taken a fatally prominent part in the political agitations of 1849, after which his position in Dresden became untenable. In fact, after the flight of the king, and the subsequent suppression of the riots by troops sent from Berlin, a formal act of accusation was drawn up against him, and he had barely time to escape to Weimar, where Liszt was at that moment engaged in preparing *Tannhäuser* for performance at the court theatre, before the storm burst upon him with a violence that seriously alarmed both his friends and himself.

Without the loss of a moment Liszt procured a passport, and escorted his guest as far as Eisenach. Wagner proceeded in all haste to Paris, and thence to Zurich, where, with few interuptions, he lived in strict retirement until the autumn of 1859. And it was during this period that most of his literary productions—including *Oper und Drama*, *Ueber das Dirigiren*, *Das Judenthum in der Musik*, and other like works—were given to the world.

[2] The composer's niece.

We have spoken of Wagner's incidental study of the legends of "Loherangrin" and "Parzival" during the time that he was preparing the libretto of *Tannhäuser.* After the production of that opera he again recurred to the subject, chose *Lohengrin* as the title for his next opera, and elaborated the conception with his usual minute and affectionate care, carrying out his new principles somewhat farther than he had hitherto ventured to do. He had completed the work before he fled from Dresden, but could not get it produced. Hoping against hope, he took the score with him to Paris, and, as he himself tells us, "when ill, miserable, and despairing, I sat brooding over my fate, my eye fell on the score of my *Lohengrin*, which I had totally forgotten. Suddenly I felt something like compassion that the music should never sound from off the death-pale paper. Two words I wrote to Liszt; his answer was the news that preparations were being made for the performance of the work on the grandest scale that the limited means of Weimar would permit. Everything that care and accessories could do was done to make the design of the piece understood. Liszt saw what was wanted at once, and did it. Success was his reward; and with this success he now approaches me, saying, 'Behold we have come thus far; now create us a new work, that we may go farther'."

Lohengrin was, in fact, produced at Weimar, under Liszt's direction, on August 28, 1850. It was a severe trial to Wagner not to be permitted to hear his own work, but he knew that all that could be done for it was done, and he responded to Liszt's appeal for a new creation by meditating upon his famous tetralogy, *Der Ring des Nibelungen*, the four divisions of which—*Das Rheingold*, *Die Walküre*, *Siegfried* and *Götterdämmerung*—though each as long as an ordinary opera, are in reality but parts of one colossal whole. At this time, also, he first began to lay out the plan of *Tristan und Isolde*, and to think over the possibilities of *Parsifal.*

It is in these later works, and in *Die Meistersinger von Nürnberg*, the first sketch for which had been made at Dresden in 1845, that the genius of Wagner reaches its culminating point; and it is in these only that his great plan for the reformation of the musical drama is fully and honestly carried out. In order to understand this plan, we must first inquire what kind of reformation was needed. What were the abuses that demanded redress? What were the causes that had led to the decline of the opera from a higher state of perfection than that which it exhibited in the middle of the 19th century—if, indeed, it ever did exhibit a higher state of perfection than that? What, in short, had been the history of the musical drama during the two centuries and a half that had elapsed between its first invention and its arrival at the condition in which Wagner found it when he first began to compose for the stage? The story is a very simple one, and may be told in a very few words; but it was not without an immensity of deep thought and earnest consideration that Wagner was able to grapple with the gigantic practical difficulties with which the case was surrounded.

The possibility of constructing a musical drama on reasonable principles was first seriously discussed during the closing years of the 16th century, at certain *réunions* of literary and artistic dilettanti, who were accustomed to meet periodically at the palazzo of Giovanni Bardi, Conte di Vernio, in Florence. The principal members of the little society were Ottavio Rinuccini the poet, Vincenzo Galilei the father of the great astronomer, Giulio Caccini, Jacopo Peri, Pietro Strozzi, and the Conte di Vernio himself. All these earnest savants were deeply imbued with the principles of the Renaissance, and regarded the traditions of classical antiquity with a reverence which led them to hold the greatest creations of modern art in undisguised contempt. The music of Palestrina and the great composers of the contrapuntal schools they utterly despised; and their one idea was to revive the system of declamation peculiar to Greek tragedy, and by means of that to produce a form of drama which could be consistently sung throughout as the trilogies of Æschylus and Sophocles were sung by the Greeks. So far their aim was identical with Wagner's. The difference lay in the means by which this aim was to be attained. Wagner himself tells us that, while occupied upon *Lohengrin*, he looked upon his work as "an experiment towards determining whether or not opera was possible." And in other places he speaks of the question whether or not the modern spirit can produce a theatre that shall stand in relation to modern culture as the theatre of Athens stood in relation to the culture of ancient Greece. He believed that this might be accomplished by reforming the opera from the standpoint of Beethoven's music. The friends of the Conte di Vernio had hoped to accomplish it by restoring the actual music of the Greek drama. But this was impossible. For Greek music was based upon a system of tonality which, even in the time of Galilei, had been obsolete for centuries. The Greek scales and ours differ so widely in their radical construction that no vocalist accustomed to the one could by any possibility sing the other. Even Peri and Vincenzo Galilei must have known this. But, pretending to ignore the fact, they made a compromise, and endeavored to imitate what they fondly conceived to be the Greek method of recitative, in the tonality of the modern scales; and in this way they struck, not upon the form of which they were in search—for that was irretrievably lost—but a new one, which rapidly developed itself into the kind of music now called recitative. This recitative—the most valuable artistic invention of the 17th century—they used as the basis of their musical drama; and, after the lapse of two centuries and a half, Wagner determined that this, and none other, must be the basis of his. Enriching it with all the beautiful accessories that had been amassed by composer after composer during its long period of progressive development, and notably with other very important accessories of his own invention, he built his drama upon it as completely as the first dramatic music was built upon it by the frequenters of the Palazzo Bardi. And in this great fact lies the secret of his gigantic reform.

The first Italian opera ever publicly performed was Jacopo Peri's *Euridice*, composed to a libretto written by Ottavio Rinuccini, and produced at Florence in 1600, in honor of the marriage of Henry IV. of France with Maria de' Medici. This most interesting work, a rare printed copy of which is preserved in the British Museum, is entirely in recitative; and the music so constructed throughout as to aid in the true dramatic expression of the words, at the expense of all attempt at what is now called melody. The operas of Monteverde, Cesti, Cavalli, and all the earlier composers of the 17th century were conceived upon the same principle. But Alessandro Scarlatti (1659–1725), aiming at a higher musical perfection, and willing to sacrifice no small amount of dramatic truth to its exigencies, introduced certain constructive forms—notably that called the "da capo"—which, while adding to the symmetrical beauty of the aria, tended eventually entirely to destroy its dramatic force and its logical consistency as an exponent of the situation presented upon the stage. Later composers carried this abuse very much farther. Handel's strong dramatic instinct kept him above the errors of his time; but his contemporaries sinned more and more deeply until, for the sake of obtaining popularity, they were ready to fill their operas with unmeaning passages, introduced solely for the purpose of showing off the skill of the favorite vocalists of the period. And so the abuse proceeded from worse to worse until, under Porpora (1686–1766) and Hasse (1699–1783), the opera at Naples and Dresden became a mere concert sung upon the stage without any trace of dramatic propriety whatever.

And now arose a reformer whose work will be remembered as long as the musical drama continues to exist. Christoph Willibald Gluck (1714–1787), disgusted with his own want of success while writing in the vicious style of the period, determined to reform it upon true dramatic principles; and in the preface to his *Alceste* (1767) he set forth those principles with a clearness which cannot possibly be misunderstood. The history of his great reform has already been narrated in detail (see GLUCK). A careful comparison of the argument laid down in the preface to *Alceste* with that set forth in Wagner's *Oper und Drama* will prove the aim of the two reformers to have been absolutely identical. That a less perfect identity should have existed with regard to the means they used for the attainment of their common end was naturally to be expected. At the outset of their career both Gluck and Wagner freely employed all the resources at their command, adding to them afterwards as circumstances permitted. But between the production of Gluck's latest and Wagner's first masterpiece art had made enormous strides; the advantage, therefore, in this respect was immeasurably on Wagner's side.

In France Gluck's principles were carried out more or less conscientiously by Méhul, Cherubini, and Spontini. In Germany they bore still richer fruit. Glorified by the genius of Mozart and Beethoven, and accepted without reserve by Weber, Spohr, Marschner, and the most enlightened of their followers in the German romantic school, they were professed, if not fully carried out, by composers of every degree. But in Italy they produced no effect whatever. Though Rossini sometimes invested his situations with a certain amount of dramatic coloring, he never attempted anything farther than this; while Mercadante, Bellini, Donizetti, and their imitators regarded melody, pure and simple, as the highest, if not the only really important, attribute of art. Under their rule the opera once more descended to the level of a concert on the stage. The effect of their example upon the lower class of German composers was fatal, and ended in the production of a form of *Singspiel*, lacking all the freshness of the Italian *Cantilena*, and noticeable only for its intolerable vapidity. Notwithstanding the attempts of Halévy and Meyerbeer to perpetuate in France the traditions of a purer epoch, the musical drama sank, under Auber and his imitators, to the level of a string of dance tunes. The 19th century had witnessed the birth of abuses as flagrant as those against which Gluck had protested in the 18th. It was Wagner's turn now to effect the desired reform, and he effected it as completely as his predecessor had done—but not in the same way. Gluck had begun by propounding a theory, and carried on the good work by consistently putting it into practice. Wagner theorized also; but for his ultimate triumph he was indebted to the power of his own creative genius—to his ceaseless endeavor to realize the preconceived ideal which neither theory nor desire for reform could ever tempt him to forget. "The nature of the subject," he says, "could not induce me, in sketching my scenes, to consider in advance their adaptability to any particular musical form, the kind of musical treatment being, in every case, suggested by the scenes themselves. I never contemplated on principle, and as a delibrate reformer, the destruction of the aria, the duet, or any other operatic form; but the disuse of these forms followed naturally from the character of my subjects." Surely no frame of mind could be more free from prejudice than this.

While exercising this unrestrained freedom of thought and action, Wagner found one particular form more useful to him than any other. Mozart in *Don Giovanni*, and Weber in *Der Freischütz*, *Euryanthe*, and *Oberon*, had availed themselves of certain characteristic musical phrases as exponents of emotional or scenic complications of peculiar interest, and had emphasized their meaning by repeating them at every recurrence of the dramatic situation. In modern musical terminology a musical phrase of this kind is now called a "leading theme" ("Leitmotif"). Wagner has employed this expedient more freely than any other composer, and in a way peculiarly his own. Not only has he introduced in his later works a leading theme for every one of the *dramatis personæ*, and for every prominent feature in the scenery or action of the play, but in many cases he even indicates the changing moods and passions of his principal characters by distinct phrases, which he combines together with a power of part-writing truly marvellous, interweaving them—as in "Siegfried's Trauermarsch," in the *Götterdämmerung*—in such sort as to present the whole story of a life and mission in the music of a single scene. Short-sighted critics have dwelt too much upon the technical ingenuity displayed in scenes of this description, and too little upon the expression thrown into them by the power of Wagner's genius. A diligent student may acquire sufficient mastery over the art of part-writing to enable him to interweave his themes with any amount of mechanical perfection, yet without a trace of the beauty displayed by Sebastian Bach in the involutions of his counter-subjects, or by Wagner in labyrinthine combinations used, not for the sake of vaunting his scholarship, but as his most potent engines of dramatic expression. The plaintive wail of the "Trauermarsch" appeals to hearers who know nothing at all of its ingenious construction, and tells its tale to them beyond all possibility of misunderstanding. It is at this point that genius steps in; and the power of Wagner's genius is irresistible.

It was during the period of his exile that Wagner matured his plans and brought his style to its culminating point of perfection; but it was not until some considerable time after his return that any of the works he then meditated were placed upon the stage. In 1855 he accepted an invitation to London, where he conducted the concerts of the Philharmonic Society with great success. In 1857 he completed the libretto of *Tristan und Isolde* at Venice, taking as the basis of his scheme the Celtic legend modified by Gottfried of Strasburg's mediæval treatment of the subject (see GOTTFRIED and ROMANCE). But the music was not completed till 1859. In that year Wagner visited Paris for the third time; and after much negotiation, in which he was nobly supported by the Prince and Princess Metternich, *Tannhäuser* was accepted at the Grand Opéra. Magnificent preparations were made for its production. It was rehearsed 164 times, 14 times with the full orchestra; and the scenery, dresses, and stage accessories generally were placed entirely under the composer's direction. More than £8000 [$38,880] was expended upon the venture; and the work was performed for the first time in the French language on March 13, 1861. But, for political reasons, a powerful clique determined to suppress both the piece and its composer. A scandalous riot was inaugurated by the members of the Parisian Jockey Club, who interrupted the performance with howls and dog-whistles; and so great was the disturbance that after the third representation the opera was withdrawn to reappear no more. Wagner was broken-hearted. But the Princess Metternich continued to befriend him, and in 1861 he received through her intercession a pardon for his political offences, with permission to settle in any part of Germany except Saxony. Even this restriction was removed in 1862.

Wagner now settled for a time in Vienna, where *Tristan und Isolde* was accepted, but abandoned after 57 rehearsals, through the incompetence of the tenor, Herr Ander. *Lohengrin* was, however, produced on May 15, 1861, when Wagner heard it for the first time. His circumstances were now extremely straitened; but better times were at hand. In 1863 he published the libretto of *Der Ring des Nibelungen*. King Louis II. of Bavaria was much struck with it, and in 1864 sent a private secretary to Wagner, who was then at Stuttgart, with an invitation to come to Munich and carry on his work there. The invitation was accepted with joy by the then almost despairing composer. The king gave him an annual grant of 1200 gulden (£120 [$583.20]), considerably enlarging it before the end of the year, and placing a comfortable house in the outskirts of the city at his disposal. The master celebrated his good fortune by composing a "Huldigungsmarsch." In the autumn he was formally commissioned to proceed with the tetralogy, and to furnish proposals for the building of a theatre and the foundation of a Bavarian music school. All seemed to promise well, but no sooner did his position seem assured than a miserable court intrigue was formed against him. His political misdemeanors at Dresden were quoted to his discredit and made the excuse for bitter persecutions, and, notwithstanding King Louis's undiminished favor, the opposition was too strong to be resisted, and Wagner was obliged to retire to Triebschen, near Lucerne, where he spent the next six years in uninterrupted study.

Der Fliegende Holländer was performed at Munich in 1864; and on June 10, 1865, *Tristan und Isolde* was produced for the first time, with Herr and Frau Schnorr in the principal parts. *Die Meistersinger von Nürnberg*, first sketched in 1845, was completed in 1867, and first performed at Munich under the direction of Herr von Bülow, June 21, 1868. The story, though an original one, is founded on an episode in the life of Hans Sachs, the poet-cordwainer of Nuremberg; and Wagner has combined its incidents with infinite ingenuity and humor. The success of the opera was very great; but the production of the tetralogy was still impracticable. The scheme for the new theatre, which was to have been designed by the architect Semper, having been abandoned, there was no opera house in Germany fit for the production of a work designed on so colossal a scale. A project was therefore started for the erection of a suitable building at Baireuth. Wagner laid the first stone of this in 1872, and the edifice was completed, after almost insuperable difficulties, in 1876.

After this Wagner resided permanently at Baireuth, in a house named Wahnfried, in the garden of which he himself built the tomb in which his remains now rest. His first wife, Wilhelmina (*née* Planer), having died in 1866, he was united in 1870 to Liszt's daughter Cosima, who had previously been the wife of Herr von Bülow. Meantime *Der Ring des Nibelungen* was rapidly approaching completion, and on August 13, 1876, the introductory portion, *Das Rheingold*, was performed at Baireuth for the first time, followed on the 14th by *Die Walküre*, on the 16th by *Siegfried*, and on the 17th by *Götterdämmerung*. The success of the work, the story of which is founded on the famous *Nibelungenlied*, was very great; and the performance, directed by Herr Hans Richter, excited extraordinary attention, but the expenses attendant upon its production were enormous, and burdened the management with a debt of £7500 [$36,450.00]. A portion of this was raised by performances at the Albert Hall, in London, at which the composer himself was present, in 1877. The remainder was met by the profits upon performances of the tetralogy—or, as Wagner himself called it, the "Bühnenfestspiel"—at Munich.

Wagner's next, last, and perhaps greatest work was *Parsifal*, based upon the legend of the Holy Grail, as set forth, not in the legend of the *Mort d'Arthur*, which fixes the home of the sacred vessel at Glastonbury, but in the poems of Chrestien de Troyes and Wolfram von Eschenbach, written in the 12th and 13th centuries, and other less known works (see the article ROMANCE, in which the subject is treated in its various aspects). The libretto was complete before his visit to London in 1877. The music was begun in the following year, and completed at Palermo, January 13, 1882. The first sixteen performances took place at Baireuth, in July and August, 1882, under Wagner's own directing, and fully realized the expectations that had been formed of them. There can indeed be no doubt that this last work, called by Wagner a "Bühnenweihfestspiel," in allusion to its mystically religious character, forms a fitting crown to his already brilliant reputation. Unhappily, the exertion of directing so many consecutive performances seems to have been too much for the veteran master's already failing strength, for towards the close of 1882 his health began to decline rapidly. He spent the autumn at Venice, in the Palazzo Vendramini, on the Grand Canal, and was well enough on Christmas Eve to conduct his own first symphony (composed in 1833), at a private performance given at the Liceo Marcello. But late in the afternoon of February 13, 1883, he was seized with a sudden attack of faintness, and on that evening he calmly breathed his last.

Wagner was buried at Wahnfried, in the tomb he had himself prepared, on February 18, and a few days afterwards King Louis rode to Baireuth alone, and at dead of night, to pay his last tribute of respect to the master he had so generously befriended.

In private life Wagner was beloved and respected by all who knew him, though in his public character he made himself innumerable enemies, and provoked an immense amount of hatred—it must be confessed, not wholly undeserved—by the violent and intemperate character of his writings. Though Meyerbeer had been extremely kind to him in Paris, he spoke of him in *Oper und Drama* with the grossest disrespect. His utterly groundless prejudice against Liszt was ultimately conquered by that great master's beautiful forbearance alone. But these things will be forgotten, while the brightness of his genius will remain the lasting heritage of art. In person he was rather below the middle height, erect in carriage, with commanding aspect and remarkable quickness of speech and gesture. That his manners were to some extent unconventional there can be no doubt, but those who knew him best deny that there was even the semblance of truth in the absurd stories that were circulated with regard to his extraordinary eccentricities.

Besides the great dramatic works we have mentioned, Wagner composed the choral music for Weber's funeral (Dresden, 1844), *Das Liebesmahl der Apostel* (Dresden, 1847), *Eine Faustovertüre* (Paris, 1839), *Kaisermarsch* (1871), *Siegfried Idyl* (1871), and a not very numerous collection of smaller pieces.[1] His literary works, published at Leipsic in 1871, fill nine thick volumes. (W. S. R.

WAGTAIL (*Wagsterd* and *Wagstyrt*, 15th century, *fide* Th. Wright, *Vol. Vocabularies*, ii. pp. 221, 253; *Uuagtale*, Turner, 1544, p. 53), the little bird that delights us equally by its neat coloration, its slender form, its nimble actions, and its sprightly notes. Since it is so generally dispersed, especially in summer, throughout the British Islands, it seems to need no further description.

The Pied Wagtail of authors, it is the *Motacilla lugubris* of modern ornithology, or *M. yarrelli* of some writers, and has for its very near ally—if indeed it be not considered merely a local race or subspecies of—the *M. alba* of Linnaeus, which has a wide range in Europe, Asia, and Africa, visiting England almost yearly, and chiefly differing from the ordinary British form in its lighter-colored tints,—the cock especially having a clear gray instead of a black back. Eleven other more or less nearly-allied species are recognized by Mr. Sharpe (*Cat. B. Brit. Museum*, x. pp. 456–496), who has laboriously treated the complicated synonymy of this group of birds. Eight of these are natives of Asia, several of them wintering in India, and one, *M. ocularis*, even occasionally reaching the west coast of North America, while the rest are confined to Africa. No colors but black, gray, or white enter into the plumage of any of the foregoing; but in the species peculiar to Madagascar, *M. flaviventris*, as well as in that which it much resembles, the so-called Gray Wagtail of Britain, *M. melanope* (*M. boarula* or *sulphurea* of some authors), a great part of the lower surface is yellow. The species last mentioned is one of the most graceful of birds, and though having a very wide range in the world at large is curiously local in its distribution in Britain, being almost wholly confined in the breeding season to the neighborhood of rocky streams in the west and north, and a line drawn from the Start Point, slightly curving to round the Derbyshire hills, and ending at the mouth of the Tees, will, it is believed, mark off its breeding-range in England. Then there is a section which by some systematists has been raised to the rank of a genus, *Budytes*, containing the Wagtails in which yellow takes a still more prominent part in their coloration. Of these, 8 species, besides several subspecies, are recognized by Mr. Sharpe (*ut supra*, pp. 503–532). One of these is the common Yellow Wagtail of England, *M. raii* (by some mistakenly called *M. campestris*), which, though very generally distributed throughout the country, is much less numerous than the Pied Wagtail, and more addicted to wet meadows; but, just as *M. lugubris* is regarded by some as a local form of the more widely-ranging *M. alba*, so does *M. raii* hold the same relation to *M. flava*, the Blue-headed Wagtail, which has a very extensive distribution in the Old World, and even crosses the Pacific to Alaska, presenting also a great number of varieties or races (most of which are treated by Mr. Sharpe as real species) differing from each other chiefly, if not solely, in the color of the head, a character which in this section can hardly be deemed specific, while their geographical range intersects and inosculates in a most puzzling manner. Much credit is due to the author just named for the enormous trouble he has taken, after study of a vast series of specimens, to clear up the questions herein involved; but it will probably be long before ornithologists can agree on many of the disputed points, and it is certain that the last word has by no means been spoken concerning them.

The genus *Motacilla* (an exact rendering of the English "Wagtail," the Dutch *Kwikstaart*, the Italian *Codatremola* and other similar words), which, as originally founded by Linnæus, contained nearly all the "soft-billed" birds of early English ornithologists, was restricted by various authors in succession, following the example set by Scopoli in 1769, until none but the Wagtails remained in it. Most of the rest are now commonly classed as *Sylviidæ* (*cf.* WARBLER), while the Wagtails with the PIPITS (*q.v.*) constitute the Family *Motacillidæ*. (A. N.)

WAHABEES, or WAHHÁBÍS. See ARABIA, vol. ii. p 228.

WAINEWRIGHT, THOMAS GRIFFITHS (1794–*c.* 1852), journalist and subject-painter, was born at Chiswick, in October, 1794. He was educated by his distant relative, Dr. Charles Burney, and served as an orderly officer in the guards, and as cornet in a yeomanry regiment. In 1819 he entered on a literary life, and began to write for *The Literary Pocket-Book*, *Blackwood's Magazine*, and *The Foreign Quarterly Review*. He is, however, most definitely identified with *The London Magazine*, to which, from 1820 to 1823, he contributed some smart but most flippant art and other criticisms, under the signatures of "James Weathercock," "Mr. Bonmot," and "Herr Vinkbooms." He was a friend of Charles Lamb,—who thought well of his literary productions, and in a letter to Bernard Barton, styles him the "kind, light-hearted Wainewright,"—and of the other brilliant contributors to the journal. He also practiced as an artist, designing illustrations to Chamberlayne's poems, and from 1821 to 1825 exhibiting in the Royal Academy figure pictures, including a Romance from Undine, Paris in the Chamber of Helen, and the Milk Maid's Song. Owing to his extravagant habits, Wainewright's affairs became deeply involved; and in 1830 he insured the life of his sister-in-law in various offices for a sum of £18,000 [$87,480]. The lady died in the December of the same year, and payment of the amount was declined by the companies on the ground of there having been misrepresentation when the insurance was effected. Wainewright now retired to France, but here he was seized by the authorities as a suspected person, and imprisoned for six months. On his being examined there was found upon his person a quantity of strychnine, a poison by means of which it was afterwards found he had destroyed, not only his sister-in-law, but also his uncle, his mother-in-law, and a Norfolkshire friend. He returned to London in 1837, but was at once arrested on a charge of forging, thirteen years before, a transfer of stock, and was sentenced to transportation for life. He died of apoplexy in Hobart Town hospital, about the year 1852.

---

[1] [He composed the *Centennial Inauguration March* for the opening of Philadelphia Exposition, 10th May, 1876.—AM. ED.]

The *Essays and Criticisms* of Wainewright were published in 1880, with an account of his life, by W. Carew Hazlitt[1]; and the history of his crimes suggested to Dickens his story of "Hunted Down," and to Bulwer Lytton his novel of *Lucretia*.

WAITZ, Georg (1813–1886), one of the most distinguished of modern German historians, was born at Flensburg, in the duchy of Schleswig, on October 9, 1813. He was educated at the Flensburg gymnasium and the universities of Kiel and Berlin. His strong bent to historical studies and the influence of Ranke early diverted him from his original purpose of studying law, and while still a student he began that series of researches in German mediæval history which was to be the occupation of his life. On graduating at Berlin in August, 1836, Waitz went to Hanover to assist Pertz in the great national work of publishing the *Monumenta Germaniæ Historica*; and the energy and learning he displayed in that position won him a summons to the chair of history at Kiel, in 1842. The young professor soon began to take an interest in politics, and in 1846 entered the provincial diet as representative of his university. His leanings were strongly German, so that he became somewhat obnoxious to the Danish Government, a fact which made an invitation in 1847 to become professor of history at Göttingen peculiarly acceptable. The political events of 1848–49, however, delayed his appearance in his new chair. When the German party in the northern duchies rose against the Danish Government, Waitz hastened to place himself at the service of the provisional Government. He was sent to Berlin to represent the interests of the duchies there, and during his absence he was elected by Kiel as a delegate to the assembly at Frankfort. Waitz was an adherent of the party who were eager to bring about a union of the German states under a German emperor; and when the king of Prussia declined the imperial crown the professor withdrew from the assembly in disappointment, and ended his active share in public life. In the autumn of 1849 Waitz began his lectures at Göttingen. His style of speaking was dry and uninteresting; but the matter of his lectures was so practical and his teaching so sound that students were attracted in crowds to his lecture-room, and the reputation of the Göttingen historical school spread far and wide. At the same time Waitz's pen was not idle, and his industry is to be traced in the list of his works and in the *Proceedings* of the different historical societies to which he belonged. In 1875 Waitz removed to Berlin to succeed Pertz as principal editor of the *Monumenta Germaniæ Historica*. In spite of advancing years the new editor threw himself into the work with all his former vigor, and took journeys to England, France, and Italy to collate works preserved in these countries. He died at Berlin on May 24, 1886. He was twice married,—in 1842 to a daughter of Schelling the philosopher, and in 1858 to a daughter of General Von Hartmann.

Waitz is often spoken of as the chief disciple of Ranke, though perhaps in general characteristics and mental attitude he has more affinity with Pertz or Dahlmann. He is an industrious and painstaking historian, who, without troubling himself about the graces of style, has collected and published an immense quantity of valuable and carefully sifted material. His special domain was mediæval German history, and he rarely travelled beyond it.

Waitz's chief works are—*Deutsche Verfassungs-Geschichte*, 8 vols., Kiel, 1844–78; 2d ed., 2 vols. only, 1865–70; *Schleswig-Holsteins Geschichte*, 2 vols., Göttingen, 1851–54 (the 3d vol. was never published); *Lübeck unter Jürgen Wullenwever und die Europäische Politik*, 3 vols., Berlin, 1855–56; and *Grundzüge der Politik*, Kiel, 1862. Among his smaller works, which, however, indicate the line of his researches, are the following: *Jahrbücher des deutschen Reichs unter Heinrich I.*, Berlin, 1837, 3d ed., 1885; *Ueber das Leben und die Lehre des Ulfila*, Hanover, 1840; *Das alte Recht der Salischen Franken*, Kiel, 1846; and *Deutsche Kaiser von Karl dem Grossen bis Maximilian*, Berlin, 1872. In conjunction with other scholars Waitz took a leading part in the publication of the *Forschungen zur deutschen Geschichte*, Munich, 1862 *sq.*, and in the *Nordalbingische Studien*, published in the proceedings of the Schleswig-Holstein Historical Society, Kiel, 1844–51. It is impossible here to do more than refer to his numerous and valuable contributions to the *Monumenta*, and to his numerous papers and criticisms published in periodicals and the proceedings of historical societies. A *Bibliographische Uebersicht über Waitz's Werke* was published by E. Steindorff at Göttingen in 1886.

Obituary notices of Waitz are to be found in the *Historische Zeitschrift*, new series, vol. xx.; in the publications for 1886 of the Berlin Academie der Wissenschaften, the Göttingen Gesellschaft der Wissenschaften, and the Hansische Geschichtsverein; in the *Historisches Jahrbuch der Görres Gesellschaft*, vol. viii.; and in the *Revue Historique*, vol. xxxi.

WAKEFIELD, a municipal and parliamentary borough and market-town of England, in the West Riding of Yorkshire, of which division it is the shire-town, is pleasantly situated on the Calder, and on the Lancashire and Yorkshire, Great Northern, and Northeastern Railway lines, 9 miles south of Leeds and 175½ miles from London. It has water communication (*via* Goole) with Hull by the Calder, which also communicates with the Lancashire canals. The streets are spacious; and, if the town has a somewhat old-fashioned appearance, and is less regularly built than several of the other large towns in Yorkshire, it enjoys the advantage of an atmosphere less polluted by smoke. The Calder is crossed by a fine bridge of eight arches, on which stands the chantry of St. Mary, a beautiful Gothic structure, 30 feet long by 24 feet wide, endowed by Edward IV. in memory of his father Richard, duke of York, killed at the battle of Wakefield in 1460; it was restored in 1847 at a cost of £3000 [$14,580]. The parish church of All Saints, consecrated by Archbishop William de Melton in 1329, but almost wholly rebuilt in the 15th century, is a beautiful building, partly Early

---

[1] [See also Talfourd's *Memorials of Charles Lamb*. According to *Men of the Reign*, Wainewright died several years later than the date above given, leaving in Tasmania many examples of his art.—Am. Ed.]

English and partly Perpendicular, consisting of chancel, nave, and tower surmounted by a fine spire rebuilt in 1860–61, the total height being 247 feet. The whole building was restored in 1857–86 from designs of the late Sir Gilbert Scott, at a cost of about £30,000 [$145,800]. The other churches are without special interest. The Elizabethan grammar school founded in 1592 was rebuilt in 1829; it is now regulated by a scheme formed by the charity commissioners. Among the principal public buildings of Wakefield are the corn exchange, erected in 1837, enlarged in 1862, and including a public concert-room; the town-hall, in the French Renaissance style, opened in 1880 at a cost of £80,000 [$388,800]; the large prison for the West Riding of Yorkshire; the West Riding sessions house; the borough police station (1879); the office of probate (1863); the mechanics' institution, with large library; the church institute and library; the fine art institution; and the public baths.` The benevolent institutions include the Clayton hospital, built on the pavilion system, opened in 1879 at a cost of £25,000 [$121,500], and the West Riding pauper lunatic asylum, with accommodation for upwards of 1400 patients. Formerly Wakefield was the great emporium of the cloth manufacture in Yorkshire, but it has within the present century been superseded in this respect by Leeds. Foreign weavers of cloth were established at Wakefield by Henry VII.; and Leland, writing in the time of Henry VIII., states that its "whole profit standeth by coarse drapery." During the 18th century it became noted for the manufacture of worsted yarn and woollen stuffs. Although its manufacturing importance is now small in comparison with that of several other Yorkshire towns, it possesses large mills for spinning worsted and carpet yarns, cocoa fibre, and China grass. It has also rag-crushing mills, chemical works, soap-works, and iron-works; and there are a large number of collieries in the neighborhood. Wakefield is the chief agricultural town in the West Riding, and has one of the largest corn-markets in the north of England. It possesses large agricultural implement and machine works, corn and flour mills, malt-works, and breweries. A large trade in corn is carried on by means of the Calder, and the building of boats for inland navigation is also a considerable industry. There are very extensive market-gardens in the neighborhood. Wakefield is the seat of the court of probate for the Wakefield district. It is governed by a mayor, eight aldermen, and twenty-four councillors. The erection of a new diocese of Wakefield was sanctioned in 1878, and the first bishop was appointed in February, 1888. The population of the municipal and parliamentary borough (area 1553 acres) in 1871 was 28,069, and in 1881 it was 30,854. By the Act of 1885 the parliamentary borough was enlarged by the addition of the suburb of Bellevue.

Wakefield is supposed by some to occupy the site of a Roman station. In Domesday the name occurs as Wackefield. Originally it consisted of three hamlets—Northgate, Kirkgate, and Westgate. The manor of Wakefield soon after the Conquest was granted to William, third earl of Warren. It formed an extensive baronial liberty extending westwards to the borders of Lancashire and Cheshire. On the death without male issue (30th June, 1347) of John, eighth earl of Warren, it reverted to the crown, and by Edward III. it was given to his fifth son, Edward de Langley, whom he created earl of Cambridge, and who in the reign of Richard II. was created duke of York. After the battle of Wakefield in 1460 it remained in the possession of the crown till the reign of Charles I., who granted it to Henry, earl of Holland. It became the marriage portion of the earl's daughter when she married Sir Gervaise Clifton of Clifton in the county of Nottingham. About 1663 Sir Gervaise Clifton sold it to Sir Christopher Clapham, whose heirs in the year 1760 sold it to the duke of Leeds, and it still remains in the possession of that family. Near Wakefield Queen Margaret inflicted a memorable defeat on Richard, duke of York (31st December, 1460). The town has possessed a corn-market since the time of the Saxons. It obtained a charter for a cattle-market 1st March, 1765. It was incorporated by Charles I. in 1626, and was governed by a constable, until it obtained a new charter under the Municipal Act, 11th March, 1848. Since 1832 it has returned a member of parliament. Under an Improvement Act obtained in 1877, the corporation were empowered to purchase the water-works belonging to a company which had been formed in 1835. In 1880 an Act was granted for obtaining a supply from Rishworth Moors, near Halifax, and the works were completed in 1888 at a cost of about £500,000 [$2,430,000].

WAKEFIELD, EDWARD GIBBON (1796–1862), colonial statesman, was born in London, March 20, 1796, of an originally Quaker family. His father, Edward Wakefield, author of *Ireland, Statistical and Political*, was a surveyor and land agent in extensive practice; his grandmother, Priscilla Wakefield, was a popular author for the young, and one of the first introducers of savings banks. Wakefield was for a short time at Westminster School, and was brought up to his father's profession, which he relinquished on occasion of his elopement at the age of 20 with Miss Pattle, the orphan daughter of an Indian civil servant. The young lady's relatives ultimately became reconciled to the match, and procured him an appointment as attaché to the British legation at Turin. He resigned this post in 1820, upon the death of his wife, to whom he was fondly attached, and, though making some efforts to connect himself with journalism, spent the years immediately succeeding in idleness, residing for the most part in Paris. In 1826 he appeared before the public as the hero of a most extraordinary adventure, the abduction of Miss Ellen Turner, daughter of William Turner, of Shrigley Park, Cheshire. Miss Turner was decoyed from school by means of a forged letter, and made to believe that she could only save her father from ruin by marrying Wakefield, whom she accordingly accompanied to Gretna Green. This time the family refused to condone his proceedings; he was tried with his confederates at Lancaster assizes, March, 1827, convicted, and sentenced to three years' imprisonment in Newgate. The marriage, which had not been consummated, was dissolved by a special Act of Parliament. A disgrace which would have blasted the career of most men made Wakefield a practical statesman and a benefactor to his country. Meditating, it is probable, emigration upon his release, he turned his attention while in prison to colonial subjects, and acutely detected the main causes of the slow progress of the Australian colonies in the enormous size of the landed estates, the reckless manner in which land was given away, the absence of all systematic effort at colonization, and the consequent discouragement of immigration and dearth of labor. He proposed to remedy this state of things by the sale of land in small quantities at a sufficient price, and the employment of the proceeds as a fund for promoting immigration. These views were expressed with extraordinary vigor and incisiveness in his *Letter from Sydney* (1829), published while he was still in prison, but composed with such graphic power that it has been continually quoted as if written on the spot. After his release Wakefield seemed disposed for a while to turn his attention to social questions at home, and produced a tract on the *Punishment of Death*, with a terribly graphic picture of the condemned sermon in Newgate, and another on incendiarism in the rural districts, with an equally powerful exhibition of the degraded condition of the agricultural laborer. He soon, however, became entirely engrossed with colonial affairs and, having impressed Stuart Mill, Colonel Torrens, and other leading economists with the value of his ideas, became a leading though not a conspicuous manager of the South Australian Company, by which the colony of South Australia was ultimately founded. In 1833 he published anonymously *England and America*, a work primarily intended to develop his own colonial theory, which is done in the appendix entitled "The Art of Colonization." The body of the work, however, is fruitful in seminal ideas, though some statements may be rash, and some conclusions extravagant. It contains the distinct proposal that the transport of letters should be wholly gratuitous—the precursor of subsequent reform—and the prophecy that, under given circumstances, "the Americans would raise cheaper corn than has ever been raised." In 1836 Wakefield published the first volume of an edition of Adam Smith, which he did not complete. In 1837 the New Zealand Association was established, and he became its managing director. Scarcely, however, was this great undertaking fairly commenced when he accepted the post of private secretary to Lord Durham on the latter's appointment as special commissioner to Canada. The Durham Report, the charter of constitutional government in the colonies, though drawn up by Charles Buller, embodied the ideas of Wakefield, and the latter was the means of its being given prematurely to the public through the *Times*, to prevent its being tampered with by the Government. He acted in the same spirit a few months later, when (about July, 1839), understanding that the authorities intended to prevent the despatch of emigrants to New Zealand, he hurried them off on his own responsibility, thus compelling the Government to annex the country just in time to anticipate a similar step on the part of France. For several years Wakefield continued to direct the New Zealand Company, fighting its battles with the colonial office and the missionary interest, and secretly inspiring and guiding many parliamentary committees on colonial subjects, especially on the abolition of transportation. The company was by no means a financial success, and many of its proceedings were wholly unscrupulous and indefensible; its great object, however, was attained, and New Zealand became the Britain of the south. In 1846 Wakefield, exhausted with labor, was struck down by apoplexy, and spent more than a year in complete retirement, writing during his gradual recovery his *Art of Colonization*. The management of the company had meanwhile passed into the hands of others, whose sole object was to settle accounts with the Government, and wind up the undertaking. Wakefield seceded, and joined Lord Lyttelton and Mr. Godley in establishing the Canterbury settlement as a Church of England colony. A portion of his correspondence on this subject has been published by his son, and is perhaps the most adequate memorial extant of the vigor and sagacity of his intellect. As usual with him, however, he failed to retain the confidence of his coadjutors to the end. In 1853, after the grant of a constitution to New Zealand, he took up his residence in the colony, and immediately began to act a leading part in colonial politics. In 1854 he appeared in the first New Zealand parliament as extra-official adviser of the acting governor, a position which excited great jealousy, and as the mover of a resolution demanding the appointment of a responsible ministry. It was carried unanimously, but difficulties, which will be found detailed in Swainson's *New Zealand and its Colonization* (ch. 12), prevented its being made effective until after the mover's retirement from political life. In December, 1854, after a fatiguing address to a public meeting, followed by prolonged exposure to a southeast gale, his constitution entirely broke down. He spent the rest of his life in retirement, dying at Wellington on 16th May, 1862.

Wakefield was a man of large views and lofty aims, and in private life displayed the warmth of heart which commonly accompanies these qualities. His main defect was unscrupulousness: he hesitated at nothing necessary to accomplish an object, and the conviction of his untrustworthiness gradually alienated his associates, and left him politically powerless. Excluded from parliament by the fatal error of his youth, he was compelled to resort to indirect means of working out his plans by influencing public men. But for a tendency to paradox, his intellectual powers were of the highest order, and as a master of nervous idiomatic English he is second to Cobbett alone. After every deduction it remains true that no contemporary showed equal genius as a colonial statesman, or in this department rendered equal service to his country.

For an impartial examination of the Wakefield system, see Leroy-Beaulieu, *De la Colonisation chez les Peuples Modernes* (3d ed. pp. 562–575 and 696–700). (R. G.)

WAKEFIELD, Gilbert (1756–1801), classical scholar, theologian and politician, was born at Nottingham, February 22, 1756, and was the son of the Rev. George Wakefield, rector of St. Nicholas. After being educated at various private schools, he proceeded at the age of sixteen to Jesus College, Cambridge, where he cultivated his classical studies diligently, but imbibed a thorough distaste for logic and mathematics. He became, however, fellow of his college in 1776, and in 1778 was ordained by the bishop of Peterborough, in a frame of mind which led him afterwards to declare that he regarded his subscription to the Articles as the most disingenuous action of his life. He held, however, curacies for a short time at Stockport and Liverpool, but in 1779, the year of his marriage, quitted the church, and accepted the post of classical tutor at the Nonconformist academy at Warrington. The institution was already on the decline and Wakefield's pugnacious temper was not likely to contribute to restore it. "It survived my arrival," he says, "four years." During this short period he published translations of Matthew and the first epistle to the Thessalonians, and treatises on inspiration and baptism, the latter of which was entirely written in nine days. He apologizes for this precipitancy as the result of "a constitutional ardor which will not suffer me to dwell long on the same subject." However inevitable, this was the source of most of his failures and mistakes. After the dissolution of the academy, he resided successively at Bramcote in Nottinghamshire, at Richmond, and at Nottingham, taking pupils and persevering in his theological and classical studies, which were considerably retarded by ill health. His most important production at this time was the *Silva Critica*, "illustrating the Scriptures by light borrowed from the philology of Greece and Rome." Three parts of this work were printed at the Cambridge university press, but, the authorities declining to proceed further with it, the author was obliged to complete it himself. In 1790 he was appointed professor of classics at the newly-founded Unitarian college at Hackney. Here he speedily became uncomfortable; his proposals for reform in the course of instruction were unacceptable to his colleagues, and his dislike to the religious services, which he carried to the length of objecting to all social worship, occasioned his resignation in June, 1791. The publication of his views on public worship deprived him of all his private pupils, and his time was henceforth devoted to authorship and the education of his children. His next important work was a new translation of the New Testament, retaining as much of the language of the Authorized Version as he deemed consistent with accuracy. This soon reached a second edition. He commenced an edition of Pope, which he was prevented from completing by the competition of Warton, but the notes were published separately. His edition of Lucretius, a work of high pretensions and little solid performance, appeared in 1796. It gained for the editor a very exaggerated reputation, but Wakefield suffered himself to be allured from the paths of literature into those of political and religious controversy. After assailing with equal acerbity writers so diverse in their principles as Wilberforce and Thomas Paine, he in January, 1798, "employed a few hours" in drawing up a reply to Bishop Watson's *Address to the People of Great Britain*. These few hours procured him two years' imprisonment in Dorchester jail. He was convicted in February, 1799, of having published a seditious libel, an offence which he had assuredly no intention of committing, and his eloquent defence was naturally thrown away upon the same jurymen who had already convicted the printer. The sympathy excited for him, however, led to a subscription, amounting to no less than £5000 [$24,300], and forming a sufficient provision for his family upon his death, which occurred September 9, 1801, shortly after his liberation, from an attack of typhus fever. He had occupied himself while in prison with the preparation of classical lectures and an English-Greek lexicon, and had corresponded on classical subjects with Charles James Fox. The letters were subsequently published.

Wakefield was one of the most honest of men, but also one of the most precipitate, narrow-minded, and presumptuous. His extreme ardor and his consciousness of integrity produced an uncharitableness verging on offensiveness, little in harmony with the many magnanimous and amiable features of his character. Rashness, opinionativeness, and contentiousness grievously marred in him the character of patriot and scholar, though they could not destroy his claim to be numbered among both.

The principal authority for his life is the second edition of his *Memoirs*, in two volumes (London, 1804). The first volume is autobiographical; the second, compiled by the editors, Rutt and Wainwright, includes several estimates of his character and performances from various sources, the most remarkable being one by Dr. Parr.

WALACHIA. See Roumania and Vlachs.

WALAFRID[1] STRABO (or Strabus, *i.e.*, "squint-eyed") was born in Germany (808–9), but the exact place is unknown. His taste for literature early displayed itself, and by the age of eighteen he had already achieved a reputation among the learned men of his age. He was educated at the monastery of Reichenau, near Constance, where he had for his teachers Tatto and Wettin, to whose visions he devotes one of his poems. Later on in life (*c.* 826–829) he passed to Fulda, where he studied for some time under Hrabanus Maurus before returning to Reichenau, of which monastery he was made abbot in 838. There is a story, based, however, on no good evidence, that Walafrid devoted himself so closely to letters as to neglect the duties of his office, owing to which he was expelled from his house; but, from his own verses, it seems that the real cause of his flight to Spires was that, notwithstanding the fact that he had been tutor to Charles the Bald, he espoused the side of his elder brother Lothair on the death of Louis the Pious in 840. He was, however, restored to his monastery in 842, and died August 16, 849, on an embassay to his former pupil. His epitaph was written by Hrabanus Maurus, whose elegiacs praise him for being the faithful guardian of his monastery.

Walafrid Strabo's works may be divided into three classes, —theological, historical, and poetical.

1. The first class includes the *Glossa Ordinaria*,[2] a large commentary on the Bible and part of the Apocrypha. This is of course to a great extent a compilation from St. Jerome, St. Augustine, St. Isidore, Bede, Hrabanus Maurus, etc. Under the same heading come the exposition of the first twenty Psalms, published by Pez (*Anecdota Nova*, iv.), and an epitome of Hrabanus Maurus's commentary on Leviticus. An *Expositio Quatuor Evangeliorum* is also ascribed to Walafrid. The treatise *De Rebus Ecclesiasticis*, dedicated to Regenbert the librarian, gives not only explanations and directions for the erection and embellishment of churches, but also instructions as regards such questions as the method of taking the holy communion and the payment of tithes. Walafrid approves of the use of images and pictures in churches, "quia pictura est quædam literatura illiterata." He had himself seen "simple folk and idiots," whom words could hardly bring to a realization of what they were told, so touched by representations of our Lord's passion that the tears ran down their faces. Last among Walafrid's theological treatises must be mentioned the *De Subversione Jerusalem Tractatus*.

2. Walafrid's chief historical works are—(*a*) the *Vita Sancti Galli*, which, though written nearly two centuries after this saint's death, is still the primary authority for his life, and (*b*) a much shorter life of St. Othmar, abbot of St. Gall (d. 759). Both these lives were based on previous ones written by Abbot Gotzbert of St. Gall (from 816–837).[3]

3. Walafrid's poetical works include a short life of St. Blaithmaic, a high-born monk of Iona, murdered by the Danes in the first half of the 9th century; a life of St. Mammes; and a *Liber de Visionibus Wettini*. This last poem, like the two preceding ones written in hexameters, was composed at the command of "Father" Adalgisus, and based upon the prose narrative of Heto, abbot of Reichenau from 806 to 822. It is dedicated to Wettin's brother Grimald. At the time he sent it to Grimald Walafrid had, as he himself tells us, hardly passed his eighteenth year, and he begs his correspondent to revise his verses, because, "as it is not lawful for a monk to hide anything from his abbot," he fears he may be beaten with deserved stripes. In this curious vision Wettin saw Charles the Great suffering purgatorial tortures because of his incontinence. The name of the ruler alluded to is not indeed introduced into the actual text, but "Carolus Imperator" form the initial letters of the passage dealing with this subject. Many of Walafrid's other poems are, or include, short addresses to kings and queens (Lothair, Charles, Louis, Pippin, Judith, etc.) and to friends (Einhard, Grimald, Hrabanus Maurus, Tatto, Ebbo, archbishop of Rheims, Drogo, bishop of Metz, etc.). His most famous poem is the *Hortulus*, dedicated to Grimald. It is an account of a little garden that he used to tend with his own hands, and is largely made up of descriptions of the various herbs he grows there and their medicinal and other uses. Sage holds the place of honor; then comes rue, the antidote of poisons; and so on through melons, fennel, lilies, poppies, and many other plants, to wind up with the rose, "which in virtue and scent surpasses all other herbs, and may rightly be called the flower of flowers." The curious poem *De Imagine Tetrici* takes the form of a dialogue.

WALCH, the name of a family of scholars.

I. Johann Georg Walch (1693–1775) was born at Meiningen, and studied at Leipsic and Jena under Olearius and Buddæus. From 1716 he was professor at Jena of philosophy, rhetoric, and poetry successively, and afterwards (from 1724) of theology. He married the only daughter of Buddæus, and in his learned and theological career followed in the footsteps of his father-in-law. His theological position was that of a very moderate orthodoxy, which had been influenced greatly by the philosophy and controversies of the Deistic period. His university lectures and published works ranged over the wide fields of ecclesiastical history in its various branches, particularly the literature and the controversies of the church, dogmatics, ethics, and pastoral theology.

Of his works the most valuable were *Bibliotheca Theologica* (1757–64); *Bibliotheca Patristica* (1770, new ed. 1834); his edition of Luther's works in 24 vols. (1740–52); *Historische und theologische Einleitung in die religiösen Streitigkeiten ausserhalb der Lutherischen Kirche*, 5 vols. (1734–36); and the companion work to this, *Streitigkeiten der Evangel. Luth. Kirche* (1730–39). His life, with a complete list of his writings, which amounted to 287, *Leben und Charakter des Kirchenraths J. G. Walch*, was published by his son C. W. F. Walch (Jena, 1777). Comp. Gass, *Protestantische Dogmatik*, iii. p. 205 *sq*.

II. Johann Ernst Immanuel Walch (1725–1778), son of the above, born at Jena in 1725, became professor of philosophy in the university in 1750, and of rhetoric and poetry in 1759. He died in 1778. He was distinguished for his philological, antiquarian, and mineralogical acquirements.

See *Lebensgeschichte Johann Ernst Im. Walch*, Jena, 1780, and Meusel's *Lexicon verstorbener deutscher Schriftsteller*, vol. xiv.

III. Christian Wilhelm Franz Walch (1726–1784), younger brother of J. E. I. Walch, was born at Jena December 25, 1726. He was educated at Jena under his father's direction, and as early as 1745–1747 lectured in the university in branches of exegesis, philosophy, and history. He then travelled with his brother J. E. I. Walch for a year through the Continent, making the acquaintance of the learned men of each country. On his return he was made professor of theology in Jena, but in 1753 he accepted an invitation to Göttingen, where he spent his life as professor of theology. He lectured on dogmatics, church history, ethics, polemics, natural theology, symbolics, the epistles of Paul, Christian antiquities, historical theological literature, ecclesiastical law, and the fathers. His permanent place amongst learned theologians rests on his works on ecclesiastical history. He here holds the third place in the important trio Semler, Mosheim, Walch. Semler was much his superior in originality and boldness, and Mosheim in clearness, method, and, elegance. But to his wide, deep, and accurate learning, to his conscientious and impartial examination of the facts and the authorities at first hand, and to "his exact quotation of the sources and works illustrating them and careful discussion of the most minute details" all succeeding historians are deeply indebted. His method is critical and pragmatic, "pursuing everywhere the exact facts and the supposed causes of the outward changes of history," leaving wholly out of sight the deeper moving principles and ideas which influence its course. He speaks of history as consisting of "the accidental changes of accidental matters." But, although he thus failed to reach the modern standard of an historian, the results of his industry and research remain as permanent historical materials.

---

[1] In the oldest MSS. this is always spelt "Walahfrid."

[2] This commentary was the one in general use during the Middle Ages, when it went by the name of *Glossa* simply.

[3] Walafrid also edited Thetmar's *Life of Louis the Pious*, prefixing a preface and making a few additions, and divided Einhard's *Vita Caroli* into chapters, adding an introduction.

His principal work was his *Entwurf einer vollständigen Historie der Ketzereien, Spaltungen, und Religionsstreitigkeiten, bis auf die Reformation*, 11 vols., Leipsic, 1762–85. It was a great advance in theological liberality that he defined a heretic on the one hand as a Christian and on the other as one in fundamental error. He thus claimed for the heretic a place in the church, while he declined to treat as heretical such differences as divided great sections of Christians. Of his other valuable works may be mentioned *Entwurf einer vollständigen Historie der Römischen Päpste* (1756, 2d ed. 1758), *Entwurf einer vollständigen Historie der Kirchenversammlungen* (1759), *Bibliotheca Symbolica Vetus* (1770), *Kritische Untersuchung vom Gebrauch der heiligen Schrift unter den alten Christen* (1779), occasioned by the controversy between Lessing and Goeze, and to which Lessing began an elaborate reply just before his death.

On C. W. F. Walch as historian see Baur, *Epochen der kirchlichen Geschichtschreibung* (1852), p. 145 *sq.*, and *Dogmengeschichte*, p. 38 *sq.* (1867, 3d ed.), Gass, *Geschichte der Protestantischen Dogmatik*, iii. p. 267 *sq.*; Meusel, *Lexicon verstorbener deutscher Schriftsteller*, vol. xiv.

IV. CARL FRIEDRICH WALCH (1734–1799), brother of the last-named, was professor of jurisprudence at Jena, and the author of several valuable legal works. He died at Jena in 1799. His son Georg Ludwig (1785–1838) was for a time professor in the Kloster gymnasium of Berlin and afterwards in the University of Greifswald. He edited valuable editions of Tacitus's *Agricola* and *Germania*.

WALCHEREN. See ZEALAND.

WALDECK-PYRMONT, a small principality in the northwest of Germany, is the eighteenth factor of the German empire in point of area, and the twenty-fourth in point of population. It consists of two separate portions lying about thirty miles apart, viz., the county (grafschaft) of Waldeck, embedded in Prussian territory between the provinces of Westphalia and Hesse-Nassau, and the principality (fürstenthum) of Pyrmont, farther to the north, between Lippe, Brunswick, and Hanover. Waldeck, with 48,580 inhabitants, comprises an area of 407 square miles, covered for the most part with hills, which culminate in the Hegekopf (2807 feet). The centre is occupied by the plateau of Corbach. The chief rivers are the Eder and Diemel, both of which eventually find their way into the Weser. Pyrmont, only 26 square miles in extent, with 8123 inhabitants, is also mountainous. The Emmer, also belonging to the Weser system, is its chief stream. The united area is thus 433 square miles, or about half the size of Cambridgeshire in England, and the united population in 1885 was 56,703. Agriculture and cattle-rearing are the main resources of the inhabitants in both parts of the principality, but the soil is nowhere very fertile. Only 55½ per cent. of the area is occupied by arable land and pasture; forests, one-tenth of which are coniferous, occupy 36 per cent. Rye is the principal crop; but oats, potatoes, and flax are also grown in considerable quantities. In 1883 the principality contained 5956 horses, 20,249 cattle, 66,704 sheep, 17,735 pigs, and 7332 goats. Iron, slate, and building-stone are worked at various points, and, along with horses, cattle, sheep, pigs, wool, and timber, form the chief exports. A few insignificant manufactures (cigars, liqueurs, earthenware, linen, knitted stockings) are carried on in some of the little towns, but both trade and manufactures are much retarded by the almost complete isolation of the country from railways. Wildungen in the extreme south of Waldeck is the terminus of a branch line, and a narrow part of Pyrmont is intersected by an unimportant line.

The capital and the residence of the prince is Arolsen (2442 inhabitants) in Waldeck; twelve smaller "towns" and about one hundred villages are also situated in the county. The only town in Pyrmont is Bad Pyrmont, with about 1500 inhabitants, at one time a highly fashionable watering-place on account of its chalybeate and saline springs. The annual number of visitors is still estimated at 13,000. Wildungen is also a spa of some repute. The inhabitants to the north of the Eder are of Saxon stock, to the south of Franconian,—a difference which is distinctly marked in dialect, costumes, and manners. Nearly all are Protestants. In 1880, when the population was 56,522, there were 53,995 Protestants, 1576 Roman Catholics, 854 Jews, and 97 others.

Waldeck-Pyrmont has one vote in the federal council and one in the imperial diet. The constitution, dating from 1852, is a reactionary modification of one carried in 1849, which in its turn had been a considerable advance upon one granted in 1816. The single chamber consists of fifteen members (three of whom represent Pyrmont), elected indirectly for three years. In the event of the male line of the present ruling family becoming extinct the female line succeeds in Waldeck, but Pyrmont falls to Prussia. In terms of a treaty concluded in 1868 for ten years and renewed in 1878 for a similar period, the finances and entire government of Waldeck-Pyrmont are managed by Prussia, the little country having found itself unable to support unassisted the military and other burdens involved by its share in the North-German Confederation. The government is conducted in the name of the prince by a Prussian "landes-director," while the state-officials are "Prussian subjects," and take the oath of allegiance to the king of Prussia. The prince of Waldeck reserves his whole rights as head of the church, and also the right of granting pardons, and in certain circumstances may exercise a veto on proposals to alter or enact laws. Education, the administration of justice, and similar matters are thus all conducted on the Prussian model; a previous convention had already handed over military affairs to Prussia. The budget for 1886 showed a revenue of £52,530 [$255,295.80] and an expenditure of £48,680 [$236,584.80]. The public debt was £117,550 [$571,293], paying interest at 4 per cent. The prince is supported by the income derived from crown-lands.

The princes of Waldeck-Pyrmont are descendants of the counts of Schwalenberg, the earliest of whom known to history was Wittekind, who died in 1137. His grandson seems to have been the first count of Waldeck. For many centuries the original possessions of the Schwalenbergs were divided among several collateral lines of counts (Waldeck, Landau, Wildungen, Eisenberg); and about 1428 Hesse obtained a right of superiority over Waldeck, in return for its protection during those troublous times. This right gave rise to important claims on the part of Hesse, which were not finally set aside until 1847, when the German diet decided that the right had come to an end with the extinction of the empire. In 1685 a *pactum primogenituræ* was made between the two surviving lines, which took effect in 1692, when the Eisenberg branch became extinct with the death of George Frederick, who had served with distinction as an imperial field-marshal, and had received the title of prince. Pyrmont had also originally belonged to a branch of the Schwalenberg family; but it had successively been held by the counts of Lippe (from 1557) and Gleichen (from 1584), before it finally fell back to Waldeck in 1625. From 1692 the lands have remained undivided under the Wildungen line, with the exception of a brief period (1805–1812) when Waldeck and Pyrmont were held by two brothers. Frederick Anthony Ulrich, who succeeded in 1706, was made prince by the emperor Charles VI. In 1807 Waldeck was a member of the Confederation of the Rhine; and in 1814 it entered the German Confederation. Its first constitution was granted in 1816 by Prince George Henry (1813–1845). George Victor, the present prince (1888), succeeded in 1845 at the age of 14, and assumed the government in 1852. The most important incident in the recent history of the principality is the conclusion of the above-mentioned treaty with Prussia, with whom it sided in the war against Austria.

WALDENBURG, an active industrial town in Prussian Silesia, is situated on the Polsnitz, 39 miles southwest of Breslau. It contains a handsome modern town-house and two churches. Among the chief industrial establishments are a large porcelain and stoneware factory, extensive fire-clay works, glass-works, and a china-painting establishment; and there are numerous flax-spinneries and linen factories in the neighborhood. Adjoining the town on the south is the village of Oberwaldenburg, with a chateau. Waldenburg lies in the centre of the extensive and productive coal-district of the Waldenburger Gebirge, a branch of the Sudetic chain. The town, which received municipal rights in the 16th century, had a population of 12,999 in 1885; in 1816 the population was 1768. There are villages of the same name in Saxony and Würtemberg.

WALDENSES, THE, a name given to the members of an heretical sect which arose in the south of France about 1170. The history of the sects of the Middle Ages is obscure, because the earliest accounts of them come from those who were concerned in their suppression, and were therefore eager to lay upon each of them the worst enormities which could be attributed to any. In later times the apologists of each sect reversed the process, and cleared that in which they were interested at the expense of others. In early times these sectaries produced little literature of their own; when they produced a literature at the beginning of the 15th century they attempted to claim for it a much earlier origin. Hence there is confusion on every side; it is difficult to distinguish between various sects and to determine their exact opinions or the circumstances under which they came into being. The polemical conception which has done much to perpetuate this confusion is that of the historical continuity of Protestantism from the earliest times. According to this view the church was pure and uncorrupt till the time of Constantine, when Pope Sylvester gained the first temporal possession for the papacy, and so began the system of a rich, powerful, and worldly church, with Rome for its capital. Against this secularized church a body of witnesses silently protested; they were always persecuted but always survived, till in the 13th century a desperate attempt was made by Innocent III. to root them out from their stronghold in southern France. Persecution gave new vitality to their doctrines, which passed on to Wycliffe and Huss, and through these leaders produced the Reformation in Germany and England.

This view rests upon a series of suppositions, and is entirely unhistorical. So far as can be discovered the heretical sects of the Middle Ages rested upon a system of Manichæism which was imported into Europe from the East (see MANICHÆISM). The Manichæan system of dualism, with its severe asceticism, and its individualism, which early passed into antinomianism, was attractive to many minds in the awakening of the 11th century. Its presence in Europe can first be traced in Bulgaria soon after its conversion in 862,[1] where the struggle between the Eastern and Western churches for the new converts opened a way for the more hardy speculations of a system which had never entirely disappeared, and found a home amongst the Paulicians in Armenia. The name of Cathari, taken by the adherents of this new teaching, sufficiently shows the Oriental origin of their opinions, which spread from Bulgaria amongst the Slavs, and followed the routes of commerce into central Europe. The earliest record of their presence there is the condemnation of ten canons of Orleans as Manichees in 1022, and soon after this we find complaints of the prevalence of heresy in northern Italy and in Germany. The strongholds of these heretical opinions were the great towns, the centres of civilization, because there the growing sentiment of municipal independence, and the rise of a burgher class through commerce, created a spirit of criticism which was dissatisfied with the worldly lives of the clergy and their undue influence in affairs.

The system of Catharism recognized two classes of adherents, *credentes* and *perfecti*. The *perfecti* only were admitted to its esoteric doctrines and to its superstitious practices. To the ordinary men it seemed to be a reforming agency, insisting on a high moral standard, and upholding the words of Scripture against the traditions of an overgrown and worldly church. Its popular aim and its rationalistic method made men overlook its real contents, which were not put clearly before them. It may be said generally that Catharism formed the abiding background of mediæval heresy. Its dualistic system and its anti-social principles were known only to a few, but its anti-ecclesiastical organization formed a permanent nucleus round which gathered a great deal of political and ecclesiastical discontent. When this discontent took any independent form of expression, zeal, which was not always accompanied by discretion, brought the movement into collision with the ecclesiastical authorities, by whom it was condemned as heretical. When once it was in conflict with authority it was driven to strengthen its basis by a more pronounced hostility against the system of the church, and generally ended by borrowing something from Catharism. The result was that in the beginning of the 13th century there was a tendency to class all bodies of heretics together: partly their opinions had coalesced; partly they were assumed to be identical.

Most of these sects were stamped out before the period of the Middle Ages came to a close. The Waldenses, under their more modern name of the Vaudois, have survived to the present day in the valleys of Piedmont, and have been regarded as at once the most ancient and the most evangelical of the mediæval sects. It is, however, by no means easy to determine their original tenets, as in the 13th and 14th centuries they were a body of obscure and unlettered peasants, hiding themselves in a corner, while in the 16th century they were absorbed into the general movement of the Reformation. As regards their antiquity, the attempts to claim for them an earlier origin than the end of the 12th century can no longer be sustained. They rested upon the supposed antiquity of a body of Waldensian literature, which modern criticism has shown to have been tampered with. The most important of these documents, a poem in Provençal, "La Nobla Leyczon," contains two lines which claimed for it the date of 1100:

> Ben ha mil e cent anez compli entierament
> Que fo scripta l'ora, car sen al derier temp.

But it was pointed out[2] that in the oldest MS. existing in the Cambridge university library the figure 4 had been imperfectly erased before the word "cent," a discovery which harmonized with the results of a criticism of the contents of the poem itself. This discovery did away with the ingenious attempts to account for the name of Waldenses from some other source than from the historical founder of the sect, Peter Waldo or Valdez. To get rid of Waldo, whose date was known, the name Waldenses or Vallenses was derived from Vallis, because they dwelt in the valleys, or from a supposed Provençal word Vaudes, which meant a sorcerer.

---

[2] Bradshaw, in *Transactions of Cambridge Antiquarian Society*, 1842. The text edited by Montet, 4to, 1887.

Putting these views aside as unsubstantial, we will consider the relation of the Waldenses as they appear in actual history with the sects which preceded them. Already in the 9th century there were several protests against the rigidity and want of spirituality of a purely sacerdotal church. Thus Berengar of Tours (999–1088) upheld the symbolic character of the Eucharist and the superiority of the Bible over tradition. The Paterines in Milan (1045) raised a protest against simony and other abuses of the clergy, and Pope Gregory VII. did not hesitate to enlist their Puritanism on the side of the papacy and make them his allies in imposing clerical celibacy. In 1110 an apostate monk in Zeeland, Tanchelm, carried their views still further, and asserted that the sacraments were only valid through the merits and sanctity of the ministers. In France at Embrun, Peter de Bruys founded a sect known as Petrobrusians, who denied infant baptism, the need of consecrated churches, transubstantiation, and masses for the dead. A follower of his a monk, Henry, gave the name to another body known as Henricians, who centred in Tours. The teachers of these new opinions were men of high character and holy lives, who in spite of persecution wandered from place to place, and made many converts from those who were dissatisfied at the want of clerical discipline which followed upon the struggle for temporal supremacy into which the reforming projects of Gregory VII. had carried the church.

It was at this time (1170) that a rich merchant of Lyons, Peter Waldo, sold his goods and gave them to the poor; then he went forth as a preacher of voluntary poverty. His followers, the Waldenses, or poor men of Lyons, were moved by a religious feeling which could find no satisfaction within the actual system of the church, as they saw it before them. Like St. Francis, Waldo adopted a life of poverty that he might be free to preach, but with this difference, that the Waldenses preached the doctrine of Christ while the Franciscans preached the person of Christ, Waldo reformed teaching while Francis kindled love; hence the one awakened antagonisms which the other escaped. For Waldo had a translation of the New Testament made into Provençal, and his preachers not only stirred up men to more holy lives but explained the Scriptures at their will. Such an interference with the ecclesiastical authorities led to difficulties. Pope Alexander III., who had approved of the poverty of the Waldensians, prohibited them from preaching without the permission of the bishops (1179). Waldo answered that he must obey God rather than man. The result of this disobedience was excommunication by Lucius III. in 1184. Thus a reforming movement became heresy through disobedience to authority, and after being condemned embarked on a course of polemical investigation how to justify its own position. Some were readmitted into the Catholic Church, and one, Durandus de Osca (1210), attempted to found an order of Pauperes Catholici, which was the forerunner of the order of St. Dominic. Many were swept away in the crusade against the ALBIGENSES (*q.v.*). Others made an appeal to Innocent III., protesting their orthodoxy. Their appeal was not successful, for they were formally condemned by the Lateran council of 1215.

The earliest definite account given of the Waldensian opinion is that of the inquisitor Sacconi about 1250.[1] He divides them into two classes, those north of the Alps and those of Lombardy. The first class hold (1) that oaths are forbidden by the gospel, (2) that capital punishment is not allowed to the civil power, (3) that any layman may consecrate the sacrament of the altar, and (4) that the Roman Church is not the church of Christ. The Lombard sect went farther in (3) and (4), holding that no one in mortal sin could consecrate the sacrament, and that the Roman Church was the scarlet woman of the Apocalypse, whose precepts ought not to be obeyed, especially those appointing fast-days. This account sufficiently shows the difference of the Waldenses from the Cathari: they were opposed to asceticism, and had no official priesthood; at the same time their objection to oaths and to capital punishment are closely related to the principles of the Cathari. Their other opinions were forced upon them by their conflict with the authority of the church. When forbidden to preach without the permission of the bishop, they were driven to assert the right of all to preach, without distinction of age or sex. This led to the further step of setting up personal merit rather than ecclesiastical ordination as the ground of the priestly office. From this followed again the conclusion that obedience was not due to an unworthy priest, and that his ministrations were invalid.

These opinions were subversive of the system of the mediæval church, and were naturally viewed with great disfavor by its officials; but it cannot fairly be said that they have much in common with the opinions of the Reformers of the 16th century. The mediæval church set forth Christ as present in the orderly community of the faithful; Protestantism aimed at setting the individual in immediate communion with Christ, without the mechanical intervention of the officers of the community; the Waldenses merely set forward a new criterion of the orderly arrangement of the church, according to which each member was to sit in judgment on the works of the ministers, and consequently on the validity of their ministerial acts. It was a rude way of expressing a desire for a more spiritual community. The earliest known document proceeding from the Waldensians is an account of a conference held at Bergamo in 1218 between the Ultramontane and the Lombard divisions, in which the Lombards showed a greater opposition to the recognized priesthood than did their northern brethren.[2]

As these opinions became more pronounced persecution became more severe, and the breach between the Waldenses and the church widened. The Waldenses withdrew altogether from the ministrations of the church, and chose ministers for themselves whose merits were recognized by the body of the faithful. Election took the place of ordination, but even here the Lombards showed their difference from the Ultramontanes, and recognized only two orders, like the Cathari, while the northern body kept the old three orders of bishops, priests, and deacons. Gradually the separation from the church became more complete; the sacraments were regarded as merely symbolical; the priests became helpers of the faithful; ceremonies disappeared; and a new religious society arose equally unlike the mediæval church and the Protestantism of the 16th century.

The spread of these heretical sects led to resolute attempts at their suppression. The crusade against the Albigensians could destroy prosperous cities and hand over lands from a heedless lord to one who was obedient to the church; but it could not get rid of heresy. The revival of preaching, which was the work of the order of St. Dominic, did more to combat heresy, especially where its persuasions were enforced by law. The work of inquisition into cases of heresy proceeded slowly in the hands of the bishops, who were too busy with other matters to find much time for sitting in judgment on theological points about which they were imperfectly informed. The greatest blow struck against heresy was the transference of the duty of inquiry into heresy from the bishops to Dominican inquisitors. The secular power, which shared in the proceeds of the confiscation of those who were found guilty of heresy, was ready to help in carrying out the judgments of the spiritual courts. Everywhere, and especially in the district round Toulouse, heretics were keenly prosecuted, and before the continued zeal of persecution the Waldenses slowly disappeared from the chief centres of population and took refuge in the retired valleys of the Alps. There, in the recesses of Piedmont, where the streams of the Pelice, the Angrogne, the Clusone, and others cleave the sides of the Alps into valleys which converge at Susa, a settlement of the Waldensians was made who gave their name to these valleys of the Vaudois. In the more accessible regions north and south heresy was exposed to a steady process of persecution, and tended to assume shifting forms. Among the valleys it was less easily reached, and retained its old organization and its old contents. Little settlements of heretics dispersed throughout Italy and Provence looked to the valleys as a place of refuge, and tacitly regarded them as the centre of their faith. At times attempts were made to suppress the sect of the Vaudois, but the nature of the country which they inhabited, their obscurity, and their isolation made the difficulties of their suppression greater than the advantages to be gained from it. However, in 1487 Innocent VIII. issued a bull for their extermination, and Alberto de' Capitanei, archdeacon of Cremona, put himself at the head of a crusade against them. Attacked in Dauphiné and Piedmont at the same time, the Vaudois were hard pressed; but luckily their enemies were encircled by a fog when marching upon their chief refuge in the valley of the Angrogne, and were repulsed with great loss. After this Charles II., duke of Piedmont, interfered to save his territories from further confusion, and promised the Vaudois peace. They were, however, sorely reduced by the onslaught which had been made upon them, and lost their ancient spirit of independence. When the Lutheran movement began they were ready to sympathize with it, and ultimately to adapt their old beliefs to those of the rising Protestantism. Already there were scattered bodies of Waldenses in Germany who had influenced, and afterwards joined, the Hussites and the Bohemian Brethren.

[2] Preger, *Beiträge zur Geschichte de Waldesier.*

The last step in the development of the Waldensian body was taken in 1530, when two deputies of the Vaudois in Dauphiné and Provence, Georges Morel and Pierre Masson, were sent to confer with the German and Swiss Reformers. A letter addressed to Œcolampadius[1] gives an account of their practices and beliefs at that time, and shows us a simple and unlettered community, which was the survival of an attempt to form an esoteric religious society within the mediæval church. It would appear that its members received the sacraments of baptism and the holy communion from the regular priesthood, at all events sometimes, but maintained a discipline of their own and held services for their own edification. Their ministers were called *barba*, a Provençal word meaning *guide*. They were chosen from among laboring men, who at the age of twenty-five might ask the body of ministers to be admitted as candidates. If their character was approved they were taught during the winter months, when work was slack, for a space of three or four years; after that they were sent for two years to serve as menial assistants at a nunnery for women, which curiously enough existed in a recess of the valleys. Then they were admitted to office, after receiving the communion, by the imposition of hands of all ministers present. They went out to preach two by two, and the junior was bound absolutely to obey the senior. Clerical celibacy was their rule, but they admit that it created grave disorders. The ministers received food and clothing from the contributions of the people, but also worked with their hands; the result of this was that they were very ignorant, and also were grasping after bequests from the dying. The affairs of the church were managed by a general synod held every year. The duties of the barbas were to visit all within their district once a year, hear their confessions, advise and admonish them; in all services the two ministers sat side by side, and one spoke after the other. In point of doctrine they acknowledged the seven sacraments, but gave them a symbolical meaning; they prayed to the Virgin and saints, and admitted auricular confession, but they denied purgatory and the sacrifice of the mass, and did not observe fasts or festivals. After giving this account of themselves they ask for information about several points in a way which shows the exigencies of a rude and isolated society, and finally they say that they have been much disturbed by the Lutheran teaching about free-will and predestination, for they had held that men did good works through natural virtue stimulated by God's grace, and they thought of predestination in no other way than as a part of God's foreknowledge.

Œcolampadius gave them further instruction, especially emphasizing the wrongfulness of their outward submission to the ordinances of the church: "God," he said, "is a jealous God, and does not permit his elect to put themselves under the yoke of Antichrist." The result of this intercourse was an alliance between the Vaudois and the Swiss and German Reformers. A synod was held in 1532 at Chanforans in the valley of the Angrogne, where a new confession of faith was adopted, which recognized the doctrine of election, assimilated the practices of the Vaudois to those of the Swiss congregations, renounced for the future all recognition of the Roman communion, and established their own worship no longer as secret meetings of a faithful few but as public assemblies for the glory of God.

Thus the Vaudois ceased to be relics of the past, and became absorbed in the general movement of Protestantism. This was not, however, a source of quiet or security. In France and Italy alike they were marked out as special objects of persecution, and the Vaudois Church has many records of martyrdom. The most severe trial to which the Vaudois of Piedmont were subjected occurred in 1655. The Congregation *de Propaganda Fide* established, in 1650, a local council in Turin, which exercised a powerful influence on Duke Charles Emmanuel II., who ordered that the Vaudois should be reduced within the limits of their ancient territory. Fanaticism took advantage of this order; and an army composed partly of French troops of Louis XIV., partly of Irish soldiers who had fled before Cromwell, entered the Vaudois valleys and spread destruction on every side. They treated the people with horrible barbarity, so that the conscience of Europe was aroused, and England under Cromwell called on the Protestant powers to join in remonstrance to the duke of Savoy and the French king. The pen of Milton was employed for this purpose, and his famous sonnet is but the condensation of his state papers. Sir Samuel Morland was sent on a special mission to Turin, and to him were confided by the Vaudois leaders copies of their religious books, which he brought back to England, and ultimately gave to the university library at Cambridge. Large sums of money were contributed in England and elsewhere, and were sent to the suffering Vaudois.

By this demonstration of opinion peace was made for a time between the Vaudois and their persecutors; but it was a treacherous peace, and left the Vaudois with a hostile garrison established among them. Their worship was prohibited, and their chief pastor, Leger, was obliged to flee, and in his exile at Leyden wrote his *Histoire Générale des Églises Vaudoises* (1684). The revocation of the edict of Nantes in 1685 began a new period of persecution, which aimed at entire extermination. This was found so difficult that the remnant of the Vaudois, to the number of 2600, were at last allowed to withdraw to Geneva. But the love of their native valleys was strong among the exiles, and in 1689 one of their pastors, Henri Arnaud, led a band of 800 men to the reconquest of their country. His first attempts against the French were successful; and the rupture between Victor Amadeus, duke of Savoy, and Louis XIV. brought a sudden change of fortune to the Vaudois. They were recognized once more as citizens of Savoy, and in the war against France which broke out in 1696 the Vaudois regiment did good service for its duke. The peace of Utrecht saw the greater part of the French territory occupied by the Vaudois annexed to Savoy, and, though there were frequent threatenings of persecution, the idea of toleration slowly prevailed in the policy of the house of Savoy. The Vaudois, who had undergone all these vicissitudes, were naturally reduced to poverty, and their ministers were partially maintained by a subsidy from England, which was granted by Queen Anne. The 18th century, however, was a time of religious decadence even among the Alpine valleys, and the outbreak of the French Revolution saw the Vaudois made subjects of France. This led to a loss of the English subsidy, and they applied to Napoleon for an equivalent. This was granted, and their church was organized by the state. On the restoration of the house of Savoy in 1816 English influence was used on behalf of the Vaudois, who received a limited toleration. From that time onwards the Vaudois became the objects of much interest in Protestant countries. Large sums of money were collected to build hospitals and churches among their valleys, and they were looked upon as the possible centre of a Protestant church in Italy. Especially from England did they receive sympathy and help. An English clergyman, Dr. Gilly, visited the valleys in 1823, and by his writings on the Vaudois Church attracted considerable attention, so that he was enabled to build a college at La Torre. Moreover, Dr. Gilly's book (*A Visit to the Valleys of Piedmont*), chancing to fall into the hands of an officer who had lost his leg at Waterloo, Colonel Beckwith, suggested an object for the energies of one who was loath at the age of twenty-six to sink into enforced idleness. Beckwith visited the valleys, and was painfully struck by the squalor and ignorance of a people who had so glorious a past. He settled among them, and for thirty-five years devoted himself to promote their welfare. He married a Vaudois peasant girl, lived amongst the people, and established no fewer than 120 schools. Moreover he brought back the Italian language which had been displaced by the French in the services of the Vaudois Church, and in 1849 built a church for them in Turin. He lived in La Torre till his death in 1862, and the name of the English benefactor is still revered by the simple folk of the valleys whom he did so much to civilize.

[1] Scultetus, *Annales*, ii. 294, etc.

According to the latest official returns the Waldensian Church had, in 1886–87, 43 churches and 38 mission stations throughout Italy. The ordained pastors numbered 37, evangelists 6, and male and female teachers 56, the total number of salaried agents being 124. The church had 4005 members, and the day schools were attended by 2206 scholars, the Sunday schools by 2482. The total income, about three-fourths of it contributions from the United Kingdom and other Protestant countries of northern Europe, amounted to upwards of £10,000 [$48,600].

The literature on the subject of the Waldensian and other sects is copious. For their rise the most important authorities are to be found in Moneta, *Adversus Catharos et Waldenses*; D'Argentré, *Collectio Judiciorum de Novis Erroribus*; Alanus, *Adversus Hæreticos*; D'Achery, *Spicilegia*, vol. i.; Gretser, *Opera*, vol. x.; Limborch, *Historia Inquisitionis*, at the end of which is the *Liber Sententiarum* of the Inquisition of Toulouse from 1307–1322. Of modern books may be mentioned Schmidt, *Histoire des Cathares*; Hahn, *Geschichte der neu-manichäischen Ketzer*; Dieckhoff, *Die Valdensier in Mittelalter*; Preger, *Beiträge zur Geschichte der Waldesier*; Cantù, *Gli Eretichi in Italia*; Comba, *Storia della Riforma in Italia*, and *Histoire des Vaudois d'Italie*; Tocco, *L'Eresia nel Medio Evo*; Montet, *Historie littérarie des Vaudois*; Lea, *History of the Inquisition of the Middle Ages*. Amongst books dealing with the more modern history of the Vaudois specially are Leger, *Histoire des l'Églises Vaudoises*; Arnaud, *Histoire de la Rentrée des Vaudois*; Perrin, *Histoire des Vaudois*; Monastier, *Histoire de l'Église Vaudoise*; Musten, *L'Israel des Alpes*; Gilly, *Excursion to the Valleys of Piedmont*, and *Researches on the Waldensians*; Todd, *The Waldensian Manuscripts*; Melia, *The Origin, Persecution, and Doctrines of the Waldensians*. (M. C.)

WALDO, Valdo, or Valdez, Peter. See p. 344 *supra*.

WALES. See England.

WALKER, a town of Northumberland, England, on the north bank of the river Tyne, 2 miles east of Newcastle-on-Tyne, with which it is connected by railway. Christ Church, in the Perpendicular style, erected in 1848, consists of chancel, nave, aisles, and tower with beautiful illuminated clock erected in 1887. The windows of the church are all monumental stained glass. There is a large colliery, in which at one time was a salt spring, which was used in the manufacture of soda, begun by permission of the Government in 1795, by a company who may be regarded as the first producers of mineral alkali and soda in England. Along the banks of the Tyne there are large iron and chemical works, coal staiths, ship- and boat-building establishments, and brick and tile works. The corporation of Newcastle-on-Tyne are lords of the manor. The town is formed of what were formerly the villages of Walker, Low Walker, and Walker Quay. It is governed by a local board of health of twelve members. The population of the urban sanitary district (area 1200 acres) in 1871 was 8888, and in 1881 it was 9527.

WALKER, Frederick (1840–1875), subject painter, was born in Marylebone, London, on May 24, 1840. While very young he began to draw from the antique in the British Museum, and at the age of sixteen he was placed in the office of Baker, an architect. The occupation proved uncongenial; at the end of eighteen months he resumed his work from the Elgin marbles at the Museum, attending art classes; and in March, 1858, he was admitted a student of the Royal Academy. He soon turned his attention to designing for the wood-engravers, and served an apprenticeship of three years with J. W. Whymper. His earliest book-illustrations appeared in 1860 in *Once a Week*, a periodical to which he contributed largely, as also to the *Cornhill Magazine*, where his admirable designs to the works of Thackeray and those of his daughter appeared. These woodcuts are among the most spirited and artistic works of their class, and entitle Walker to rank with Millais at the very head of the draughtsmen of our time who have dealt with scenes of contemporary life. In the intervals of work as a book-illustrator he practiced painting in water-colors, his subjects being frequently more considered and refined repetitions in color of his black and white designs. Among the more notable of his productions in water-color are Spring, a Fishmonger's Shop, the Ferry, and Philip in Church, which gained a medal in the Paris International Exhibition of 1867. He was elected an associate of the Society of Painters in Water Colors in 1864, and a full member in 1866; and in 1871 he became an associate of the Royal Academy. His first oil picture, the Lost Path, was exhibited in the Royal Academy in 1863, where it was followed in 1867 by the Bathers, one of the artist's finest works, in 1868 by the Vagrants, now in the National Gallery, in 1869 by the Old Gate, and in 1870 by the Plough, a powerful and impressive rendering of ruddy evening light, of which the landscape was studied in Somerset. In 1871 he exhibited his tragic life-sized figure of a Female

Prisoner at the Bar, a subject which now exists only in a finished oil study, for the painter afterwards effaced the head, with which he was dissatisfied, and was prevented by death from again completing the picture. The last of his fully successful works was the Harbor of Refuge, shown in 1872, for the Right of Way, exhibited in 1875, bears evident signs of the artist's failing strength. In the end of 1873 he made a journey to Algiers for his health, but, returning in the bitter English spring, he was again prostrated; and on June 5, 1875, he died of consumption at St. Fillan's, Perthshire.

The works of Frederick Walker are thoroughly original and individual, both in the technique of their color and execution and in their view of nature and humanity. His color, especially in his water-colors, is pure, powerful, and full of delicate gradations: he had an admirable sense of design, and the figures of his peasants at their daily toil show a grace and sweeping largeness of line which recalls the antique; while the sentiment of his subjects is unfailingly refined and poetic.

WALKER, SEARS COOK (1805–1853), astronomer, was born at Wilmington, Massachusetts, U. S., on March 28, 1805. He kept a school at Philadelphia till 1845, when he was appointed assistant at the Washington observatory. Shortly afterwards he took charge of the astronomical department of the United States Coast Survey, where he was among the first to make use of the electric telegraph for the purpose of determining the difference of longitude between two stations [see vol. xxiii. p. 422], and he introduced the method of registering transit observations electrically by means of a chronograph. He also investigated the orbit of the newly discovered planet Neptune.[1] He died at Cincinnati on January 30, 1853.

WALLACE, SIR WILLIAM, the most popular national hero of Scotland, is believed to have been the second son of Sir Malcolm Wallace of Elderslie and Auchinbothie, in Renfrewshire. The date of his birth is not certainly ascertained, but is usually given as 1270. The only authority for the events of his early life is the metrical history of Blind Harry. That authority cannot be implicitly relied on, though we need not conclude that the minstrel invented the stories he relates. He lived about two centuries later than Wallace, during which a considerable body of legend had probably gathered round the name, and these popular "gestis" he incorporates in his narrative. At the same time he professes to follow as his "autour" an account that had been written in Latin by John Blair, the personal friend and chaplain of Wallace himself. As Blair's account has perished, we cannot tell how far the minstrel has faithfully followed his authority, but some comparatively recent discoveries have confirmed the truth of portions of the narrative which had previously been doubted. At best, however, his authority must be regarded with suspicion, except when it is confirmed by other and more trustworthy evidence.

Only for a period of less than two years in his life—from the beginning of the insurrection in 1297 to the battle of Falkirk—does Wallace come before us in the clearest historical light. With the exception of one or two glimpses of him that we obtain from authentic historical documents, the recorded events of his later as of his earlier life rest on no more certain authority than that of Blind Harry.

In his boyhood, according to the usual accounts, he resided for some time at Dunipace, in Stirlingshire, with an uncle, who is styled "parson" of the place. By this uncle he was partially educated, and from him he imbibed an enthusiastic love of liberty. His education was continued at Dundee, where he made the acquaintance of John Blair. On account of an incident that happened at Dundee—his slaughter of a young Englishman named Selby, for an insult offered to him—he is said to have been outlawed, and so driven into rebellion against the English. Betaking himself to the wilds of the country, he gradually gathered round him a body of desperate men whom he led in various attacks upon the English. In consequence of the success of these early enterprises his following largely increased, several of the more patriotic nobles—including the steward of Scotland, Sir Andrew Moray, Sir John de Graham, Douglas the Hardy, Wishart, bishop of Glasgow, and others—having joined him. His insurrection now became more open and pronounced, and his enterprises of greater importance. An attack was made upon the English justiciar, Ormsby, who was holding his court at Scone. The justiciar himself escaped, but many of his followers were captured or slain. The burning of the Barns of Ayr, the quarters of English soldiers, in revenge for the treacherous slaughter of his uncle, Sir Ronald Crawford, and other Scottish noblemen, followed. The success of these exploits induced the English king to take measures for staying the insurrection. A large army, under the command of Sir Henry Percy and Sir Robert Clifford, was sent against the insurgents, and came up with them at Irvine. Dissensions broke out among the Scottish leaders, and all Wallace's titled friends left him and made submission to Edward, except the ever faithful Sir Andrew Moray. The treaty of Irvine, by which these Scottish nobles agreed to acknowledge Edward as their sovereign lord, is printed in Rymer's *Fœdera*. It is dated 9th July, 1297, and is the first public document in which the name of Sir William Wallace occurs. Wallace retired to the north, and although deserted by the barons was soon at the head of a large army. The vigor and success of his operations was such that in a short time he succeeded in recovering almost all the fortresses held by the English to the north of the Forth. He had begun the siege of Dundee when he received information that an English army, led by the earl of Surrey and Cressingham the treasurer, was on its march northward. Leaving the citizens of Dundee to continue the siege of the castle, he made a rapid march to Stirling. Encamping in the neighborhood of the Abbey Craig—on which now stands the national monument to his memory—he watched the passage of the Forth. After an unsuccessful attempt to bring Wallace to terms, the English commander, on the morning of 11th September, 1297, began to cross the bridge. When about one-half of his army had crossed, and while they were still in disorder, they were attacked with such fury by Wallace, that almost all—Cressingham among the number—were slain, or driven into the river and drowned. Those on the south side of the river were seized with panic and fled tumultuously, having first set fire to the bridge. The Scots, however, crossed by a ford, and continued the pursuit of the enemy as far as Berwick. Sir Andrew Moray fell in this battle. The results of it were important. The English were everywhere driven from Scotland. To increase the alarm of the English, as well as to relieve the famine which then prevailed, Wallace organized a great raid into the north of England, in the course of which he devastated the country to the gates of Newcastle. On his return he was elected guardian of the kingdom. In this office he set himself to reorganize the army and to regulate the affairs of the country. His measures were marked by much wisdom and vigor, and for a short time succeeded in securing order, even in the face of the jealousy and opposition of the nobles. Edward was in Flanders when the news of this successful revolt reached him. He hastened home, and at the head of a great army entered Scotland in July, 1298. Wallace was obliged to adopt the only plan of campaign which could give any hope of success. He slowly retired before the

---

[1] [He showed that this planet was the same body as a star observed by Lalande in 1795 and thus was enabled to determine its orbit with great accuracy. Many of Walker's investigations were made conjointly with his half-brother, Professor E. O. Kendall of Philadelphia.—AM. ED.]

English monarch driving off all supplies and wasting the country. The nobles as usual for the most part deserted his standard. Those that remained thwarted his councils by their jealousies. His plan, however, came very near being successful. Edward, compelled by famine, had already given orders for a retreat when he received information of Wallace's position and intentions. The army, then at Kirkliston, was immediately set in motion, and next morning (July 22, 1298) Wallace was brought to battle in the vicinity of Falkirk. After an obstinate fight the Scots were overpowered and defeated with great loss. Among the slain was Sir John de Graham, the bosom friend of Wallace, whose death, as Blind Harry tells, threw the hero into a frenzy of rage and grief. The account of his distress is one of the finest and most touching passages in the poem. With the remains of his army Wallace found refuge for the night in the Torwood—known to him from his boyish life at Dunipace. He then retreated to the north, burning the town and castle of Stirling on his way. He resigned the office of guardian, and betook himself again to a wandering life and a desultory and predatory warfare against the English. At this point his history again becomes obscure. He is known to have paid a visit to France, with the purpose of obtaining aid for his country from the French King. This visit is narrated with many untrustworthy details by Blind Harry; but the fact is established by other and indisputable evidence. When in the winter of 1303–4 Edward received the submission of the Scottish nobles, Wallace was expressly excepted from all terms. And after the capture of Stirling Castle and Sir William Oliphant, and the submission of Sir Simon Fraser, he was left alone but resolute as ever in refusing allegiance to the English king. A price was set upon his head, and the English governors and captains in Scotland had orders to use every means for his capture. On the 5th August, 1305, he was taken—as is generally alleged through treachery—at Robroyston, near Glasgow, by Sir John Menteith, carried to the castle of Dumbarton, and thence conveyed in fetters and strongly guarded to London. He reached London on the 22d August, and next day was taken to Westminister Hall, where he was impeached as a traitor by Sir Peter Mallorie, the king's justice. To the accusation Wallace made the simple reply that he could not be a traitor to the king of England, for he never was his subject, and never swore fealty to him. He was found guilty and condemned to death. The sentence was executed the same day with circumstances of unusual cruelty.

The cause of national independence was not lost with the life of Wallace. Notwithstanding the cruelty and indignity amid which it terminated, that life was not a failure. It has been an inspiration to his countrymen ever since. The popular ideas regarding his stature, strength, bodily prowess, and undaunted courage are confirmed by the writers nearest his own time—Wyntoun and Fordun. And indeed no man could in that age have secured the personal ascendency which he did without the possession of these qualities. The little we know of his statesmanship during the short period he was in power gives proof of political wisdom. His patriotism was conspicuous and disinterested. He was well skilled in the modes of warfare that suited the country and the times. That he failed in freeing his country from the yoke of England was due chiefly to the jealousy with which he was regarded by the men of rank and power. But he had a nobler success in inspiring his countrymen with a spirit which made their ultimate conquest impossible. (A. F. H.)

WALLACE, WILLIAM (1768–1843), mathematician, was born on September 23, 1768, at Dysart, in Fifeshire, where he received his school education. In 1784 his family removed to Edinburgh, where he himself was set to learn the trade of a bookbinder; but his taste for mathematics had already developed itself, and he made such use of his leisure hours that before the completion of his apprenticeship he had made considerable acquirements in geometry, algebra, and astronomy. He was further assisted in his studies by Professors Robison and Playfair, to whom his abilities had become known. After various changes of situation, dictated mainly by a desire to gain time for study, he became assistant teacher of mathematics in the academy of Perth in 1794, and this post he exchanged in 1803 for a mathematical mastership in the Royal Military College at Great Marlow (afterwards at Sandhurst). In 1819 he was chosen to succeed Playfair in the chair of mathematics at Edinburgh, and in 1838, when compelled by ill-health to retire, he received a Government pension for life. He died in Edinburgh, after a lingering illness, on April 28, 1843.

In his earlier years Wallace was an occasional contributor to Leybourne's *Mathematical Repository* and to the *Gentleman's Mathematical Companion*. Between 1801 and 1810 he contributed the articles "Algebra," "Conic Sections," "Trigonometry," and several others in mathematical and physical science to the fourth edition of the *Encyclopædia Britannica*, and some of these were retained in subsequent editions from the fifth to the eighth inclusive. He was also the author of the principal mathematical articles in the *Edinburgh Encyclopædia*, edited by Brewster (1808–30). Subjoined is a list of his more important papers contributed to the *Transactions* of the Royal Society of Edinburgh: "Geometrical Porisms, with Examples of their Applications to the Solution of Problems" (1796); "A new Method of expressing the Coefficients in the Development of the Formula which represents the Mutual Perturbation of two Planets" (1802); "New Series for the Quadrature of the Conic Sections, and the Computation of Logarithms" (1808; "Investigation of Formulæ for finding the Logarithms of Trigonometrical Quantities from one another" (1823); "Account of the Invention of the Pantograph, and a Description of the Eidograph," the latter being an instrument of his own invention (1831); "Analogous Properties of Elliptic and Hyperbolic Sectors" (1839); and "Solution of a Functional Equation, with its Application to the Parallelogram of Forces and the Curve of Equilibration." In 1836 he contributed "Two Elementary Solutions of Kepler's Problem by the Angular Calculus" to the Royal Astronomical Society; and for the Cambridge Philosophical Society he wrote a paper on "Geometrical Theorems and Formulæ, particularly applicable to some Geodetical Problems."

WALLASEY, a town of Cheshire, England, on rising ground near a branch of the Mersey called Wallasey Pool, which bounds it on the S.E., while to the N.W. is the Irish Sea. It is about 2 miles northwest of Birkenhead, of which part of it is practically a suburb, and Wallasey Pool is now occupied by the Great Float, forming an immense dock of about 150 acres. The church of St. Hilary, rebuilt in the 18th century, with the exception of the tower bearing date 1536, having been gutted by fire in 1857, the whole, except the tower, was rebuilt in the Early English style. The free grammar school, built and endowed by Major Henry Meols in 1656–57, was re-established under a scheme of the charity commissioners, and reopened in 1876. On the shore of the Irish Sea is Leasowe Castle, once known as Mock-Beggar Hall, and supposed to have been erected by the earls of Derby in the reign of Elizabeth, in order to witness the races. On the sides of Wallasey Pool are remains of a submarine forest bed, in which various animal skeletons have been found. The population of the urban sanitary district (which includes Liscard and Poulton, with Seacomb, the total area being 3408 acres) in 1871 was 14,944, and in 1881 it was 21,192.

At the Conquest Wallasey formed part of the possessions of Robert de Rhuddlan, and on his decease became part of the fee of Halton. In the reign of Elizabeth it had a small port, to which there belonged three barques and fourteen men. In 1668 the manor was possessed by the earl of Derby, but various parts afterwards became alienated. For a considerable time the horse races held on what was then a common had considerable reputation, but they were discontinued in 1760. At these races the duke of Monmouth, natural son of Charles II., once rode his own horse and won the plate.

WALLA WALLA, a city and the county seat of Walla Walla county, Washington Territory, United States, is situated in a valley on Mill Creek, a tributary of the Walla Walla, in a fertile agricultural region, devoted mainly to the growth of wheat, fruit, and vegetables. The population which in 1880 was 3588, was estimated at 5000 in 1888.

WALLENSTEIN (properly WALDSTEIN), ADALBERT EUSEBIUS VON (1583–1634), duke of Friedland, Sagan, and Mecklenburg, was born on the hereditary estate of his family, Hermanic, in Bohemia, on 15th September, 1583. His parents were Protestants, and in early youth he attended the school of the Brothers of the Common Life at Koschumberg. After the death of his parents he was sent by his uncle, Slawata, to the Jesuit college at Olmütz, where he joined the Roman Catholic Church. In 1599 he went to the university of Altdorf, which he had to leave in consequence of some boyish follies. Afterwards he studied at Bologna and Padua, and, according to the custom of the young nobles of the time, visited many places in southern and western Europe. While in Padua, he gave much attention to astrology, and during the rest of his life he seems never to have wavered in the conviction that he might trust to the stars for indications as to his destiny.

For some time Wallenstein served in the army of the emperor Rudolph II. in Hungary. In 1606 he returned to Bohemia, and soon afterwards he married a rich widow, Lucretia Nikossie von Landeck, whose lands in Moravia he inherited after her death in 1614. Supporting the archduke Ferdinand in his war with Venice, he became favorably known at court, and his influence was increased by his marriage with Isabella Katharina, daughter of Count Harrach, a confidential adviser of the emperor Matthias.

In the disturbances which broke out in Bohemia in 1618—disturbances which proved to be the beginning of the Thirty Years' War—advances were made to Wallenstein by the revolutionary party; but he preferred to associate himself with the imperial cause, for which he repeatedly fought with marked success. In 1620 he was made quartermaster-general of the army of the League, commanded by Tilly. Wallenstein was not present at the battle of the Weissenberg (1620), but soon afterwards he did brilliant service as second in command of the army which opposed Bethlen Gabor in Moravia.

The battle of the Weissenberg placed Bohemia absolutely at the mercy of the emperor Ferdinand; and Wallenstein, who was a man of insatiable ambition, knew how to turn the prevailing confusion to his own advantage. Through no very honorable means he secured the inheritance of the great estates belonging to his mother's family, and the emperor sold to him on easy terms vast tracts of confiscated lands. His possessions he was allowed to form into a territory called Friedland, and he was raised in 1622 to the rank of an imperial count and palsgrave, in 1623 to that of a prince. In 1625 he was made duke of Friedland. In the government of his principality he displayed much vigor and foresight. He not only placed the administration of justice on a firm basis, but by many wise measures developed agriculture and mining and manufacturing industries.

The early successes of the emperor Ferdinand in the Thirty Years' War were due chiefly to the army of the League, which he could only indirectly control. When he was threatened with a coalition of the Protestant powers, with Christian IV. of Denmark as his most active enemy, he was anxious to have an army of his own, which should be more devoted than that of the League to the interests of his dynasty. He had not, however, the means of securing the fulfilment of his wish. In these circumstances Wallenstein saw that he might have an opportunity of playing a great part in the events of the age; and accordingly, early in 1626, he offered to raise an army for the imperial service. After some negotiations the offer was accepted, the understanding being that the troops were to be maintained at the cost of the countries they might occupy. Wallenstein had always been a popular commander, and great numbers of recruits flocked to his standard, so that he soon found himself at the head of an army of 30,000 men. With this force he marched northwards for the purpose of co-operating with Tilly against Christian IV. and Mansfeld. No engagement was fought in 1625; but on April 25, 1626, Wallenstein defeated Mansfeld at the bridge of Dessau, and later in the year Christian IV. was defeated by Tilly at Lutter. Wallenstein pursued Mansfeld into Hungary, where the Protestant general effected a junction with Bethlen Gabor. Before the end of the year Mansfeld died, and Bethlen Gabor came to terms with the emperor.

Having established peace in Hungary, Wallenstein proceeded, in 1627, to clear Silesia of some remnants of Mansfeld's army; and at this time he bought from the emperor the duchy of Sagan, his outlay in the conduct of the war being taken into account in the conclusion of the bargain. He then joined Tilly in the struggle with Christian IV., and afterwards took possession of the duchy of Mecklenburg, which was granted to him in reward for his services, the hereditary dukes being displaced on the ground that they had helped the Danish king. He failed to capture Stralsund, which he besieged for several months in 1628. This was his first important reverse and it caused him bitter disappointment, for he had hoped that by obtaining free access to the Baltic he might be able to make the emperor as supreme at sea as he seemed to be on land. It was a part of Wallenstein's scheme that he should obtain possession of the Hanseatic towns, and through them destroy the naval power of the Scandinavian kingdom, the Netherlands, and England. This plan completely broke down when he was compelled to withdraw his troops from the brave city which he had sworn to take even if it were bound with chains to heaven. Notwithstanding this check, the imperial cause prospered; and early in 1629 Christian IV. was obliged to accept terms of peace. About the same time Ferdinand issued the famous edict of restitution, which excited deep resentment in every Protestant state in the realm.

Meanwhile Wallenstein had made for himself a host of enemies among the princes of the empire. They regarded him as an upstart, and complained of the incessant exactions of his army. Moreover, it was by no means clear what he intended to do with the great force he had gathered around him. He was sometimes heard to speak ominously of the arrogance of the princes, and it appeared probable that he might try to bring them, Catholics and Protestants alike, into rigid subjection to the crown. Again and again, therefore the emperor was advised to dismiss him from his command. Ferdinand was very unwilling to part with one who had served him so well; but the demand was pressed so urgently by the electors in 1630 that he had no alternative, and in September of that year envoys were sent to Wallenstein to announce his removal. Had the emperor declined to take this course, the princes would probably have combined against him; and the result would have been a civil war even more serious than that which had already brought so many disasters upon the country. This was perfectly understood by Wallenstein, who therefore accepted the emperor's decision calmly, and retired to Gitschin, the capital of his duchy of Friedland.

Some months before the dismissal of Wallenstein, Gustavus Adolphus had landed in Germany, and it soon became obvious that he was by far the most formidable of the enemies with whom the emperor had yet had to contend. Tilly was defeated at Breitenfeld and in the battle of the Leth, where he received a mortal wound; and Gustavus advanced to Munich, while Bohemia was occupied by his allies the Saxons. After the battle of Breitenfeld the emperor entreated Wallenstein to come once more to his aid. Wallenstein at first declined; he had, indeed, been secretly negotiating with Gustavus Adolphus, in the hope that he might thus be able to maintain his hold over his great possessions. In the end, however, he accepted the offers made to him by Ferdinand, and in the spring of 1632 he took the field with an army of more than 40,000 men. This army was placed absolutely under his control, so that he assumed the position of an independent prince rather than of an ordinary subject.

His first aim was to drive the Saxons from Bohemia —an object which he accomplished without serious difficulty. Then he advanced against Gustavus Adolphus, who attacked him near Nuremberg on the 3d of September, but was driven back. On the 16th of November 1632, a decisive battle was fought at Lützen, in Saxony. In this battle the imperialists were routed, but Gustavus Adolphus was killed.

To the dismay of Ferdinand, Wallenstein made no use of the opportunity provided for him by the death of the Swedish king, but withdrew to winter quarters in Bohemia. In the campaign of 1633 much astonishment was caused by his apparent unwillingness to attack the enemy. The truth was that he was preparing to desert the emperor. That he sincerely desired to secure for Germany the benefits of peace is probable enough, but it is certain that he was also resolved to make for himself a position of commanding importance. He entered into negotiations with Saxony, Brandenburg, Sweden, and France; and one of his conditions was that the possession of the kingdom of Bohemia should be guaranteed to him. He had vast and somewhat vague schemes for the reorganization of the entire constitutional system of the empire, and he himself was to have supreme authority in determining the political destinies of his country.

Irritated by the distrust excited by his proposals, and anxious to make his power felt, he at last assumed the offensive, and in October he defeated the Swedes at Steinau. Soon afterwards he entered Lusatia and took Görlitz and Bautzen, and despatched a troop of cavalry as far as Berlin. He then resumed the negotiations, and pressed for a full and final acceptance of his plans. In December he retired with his army to Bohemia, fixing his headquarters at Pilsen.

It had soon been suspected in Vienna that Wallenstein was playing a double part, and the emperor, encouraged by the Spaniards at his court, anxiously sought for means of getting rid of him. Wallenstein was well aware of the designs formed against him, but displayed little energy in his attempts to thwart them. This was due in part, no doubt, to ill health, in part to the fact that he trusted to the assurances of his astrologer, Seni, with whom he often conferred. He also felt confident that when the time came for his army to decide between him and the emperor the decision would be in his own favor.

His principal officers assembled around him at a banquet on the 12th January, 1634, when he submitted to them a declaration to the effect that they would remain true to him. This declaration they signed. More than a month later a second paper was signed; but on this occasion the officers' expression of loyalty to their general was associated with an equally emphatic expression of loyalty to their emperor. By this time Wallenstein had learned that he had too easily allowed himself to be lulled into a sense of security, and that he needed to act warily. On the 24th of January the emperor had signed a secret patent removing him from his command and requiring the army to obey Count Gallas; and imperial agents had been laboring to undermine Wallenstein's influence. Another patent charging Wallenstein and two of his officers with high treason, and naming the generals who were to assume the supreme command of the army, was signed on the 18th February, and published in Prague.

When Wallenstein heard of the publication of this patent, he realized the full extent of his danger, and on the 23d February, accompanied by several of his most intimate friends, and guarded by about 1000 men, he went from Pilsen to Eger, hoping to obtain the protection of the Protestant general Bernard of Weimar. After the arrival of the party at Eger, Colonel Gordon, the commandant, and Colonels Butler and Leslie agreed to rid the emperor of his enemy. On the evening of the 25th February, Wallenstein's supporters Illo, Kinsky, Terzky, and Neumann were received at a banquet by the three colonels, and murdered by several dragoons. Butler, accompanied by Captain Devereux and a number of soldiers, then hurried to the house where Wallenstein was staying, and broke into his room. He had just taken a bath and was standing in his shirt ready to go to bed. He was instantly killed by a thrust of Devereux's partisan. The body was taken to the citadel, and laid beside those of his murdered comrades. Wallenstein was buried at Gitschin, but in 1732 the remains were removed to the castle chapel of Münchengrätz.

No direct orders for the murder of Wallenstein had been issued, but it was well understood that tidings of his death would be welcome at court. The murderers were handsomely rewarded for what they had done, and their deed was commended as a necessary act of justice.

Wallenstein was tall, thin, and pale, with reddish hair, and eyes of remarkable brilliancy. He was of a proud and imperious temper, and was seldom seen to laugh. He worked hard, and invariably acted on the motto that if speech is silvern silence is golden. In times of supreme difficulty he listened carefully to the advice of his counsellors, but the final decision was always his own, and he rarely revealed his thoughts until the moment for action arrived. Few generals have surpassed him in the power of quickly organizing great masses of men and of inspiring them with confidence and enthusiasm; and as a statesman he was distinguished for the boldness of his conceptions and the liberality of his sentiments. All his good qualities were, however, marred by a furious lust for power, in the gratification of which he allowed no scruples to stand in his way.

(J. SI.)

WALLER, Edmund (1605–1687), enjoyed in the latter half of his long life a high reputation as a poet, which has been partly fixed by the compliments of Dryden and Pope. Waller is a singular and piquant figure in the history of the 17th century; his relations with Charles I., with the Long Parliament, with Cromwell, with Charles II., his position as a poet, as a courtier, as a privileged water-drinker among the bibulous Restoration wits, form a combination that has no parallel. The character might be paralleled, but the run of incidents is unique. He was born at Coleshill, in Hertfordshire, March 3, 1605, and came of distinguished ancestry, landed gentry, with estates in Kent and other counties, and prominent places in the public service from the reign of Henry V. downwards. He inherited a position of difficulty in view of the civil strife that began when he reached manhood; his mother was herself an ardent Royalist, but was connected by blood with Hampden and by marriage with Cromwell. His father died when he was eleven years old. He entered parliament at sixteen, and sat also in the first and in the third parliaments of Charles I. He was thus, as Clarendon put it, nursed in parliament, and this early experience helped him to make a figure afterwards; but he took no active part at the time, the chief use that he made of his advantages as a courtier and a youth of fashion being to marry a wealthy city heiress. With this addition to the handsome fortune left him by his father, he retired to his estate at Beaconsfield and studied literature. This was about 1632.

When he first began to write verses is a doubtful and disputed point. Clarendon says that he began at an age when most men leave off, and if we put this at thirty there is no published or even probable evidence to the contrary; but, on the other hand, it is argued that he began at the age of eighteen, in 1623, this being the date of the subject of his first poem,—Prince Charles's escape from a storm at St. Andero. This earliest date must be increased by at least two years, the whole point of the poem being Charles's marriage with his queen Henrietta, which took place in 1625. The exact date of his beginning acquires some interest from Johnson's dictum that he wrote as smoothly at eighteen as at eighty, "smoothness," being his established merit; and the difficulty of determining the date arises from his not having "gathered his sticks into a faggot" and published till 1645. The incidents that furnished him with themes for his peculiar artificial and decorative treatment occurred long before,—for example, the duke of Buckingham's death in 1628, the taking of Salle in 1632, the repair of St. Paul's in 1633, the death of the earl of Carlisle in 1636, his courtship of Lady Dorothy Sidney, "Saccharissa"—between the death of his first wife in 1634, and Saccharissa's marriage to another in 1639. But that the poems, as we now have them, were written immediately after the incidents glorified in his verse is an uncertain assumption, considering his elaborating habits, the strongly Royalist tone of his verses on public events, and the express statement of Clarendon, who was likely to have known if copies had been circulated in the society of the court long before they appeared in print. If they were at least retouched by him between the ages of thirty and forty, the wonder of his uniformity of manner from first to last—which, after all, has been somewhat exaggerated—is considerably lessened.

In the struggle between king and parliament, Waller tried at first to mediate, holding the king's demands unconstitutional, but endeavoring through his advisers to induce him to modify them. He made such a mark as a speaker in the Short Parliament that at the opening of the Long Parliament he was chosen by the Commons to conduct the impeachment of Judge Crawley for his ship-money decision. Thereafter, as the struggle became fiercer, with a view apparently to prevent parliament from proceeding to extremities, he engaged in what was known as Waller's plot. The object of the plot seems to have been to restrain the extreme Parliamentarians by some public declaration of moderate opinion, but it was complicated with another plot, the object of which was to assist the king with armed force. All Waller's relations, except his mother, were anti-Royalist, and it is said that his complicity was discovered by domestic treachery. He behaved with the most abject meanness when arrested by order of Pym on May 31, 1643, saved himself by at once turning informer and making disclosures that were at least unreserved, and was let off eventually with a fine of £10,000 [$48,600] and banishment. It was from his exile in Paris, in 1645, that he directed his first publication of poems. He lived there in high repute as a wit and a munificent host till 1654, when Cromwell, at the intercession of his anti-Royalist relatives, allowed him to return to England, and try to mend his impaired estate. He celebrated the Protector's greatness in a lofty panegyric, and Cromwell is said to have relished his pleasant qualities as a companion. It deserves to be noted, as evidence of a real admiration, that he wrote also a lament "Upon the Death of the Lord Protector," when the sincerity of his panegyric was less open to question. The poem contains two famous lines of pathos—

> Under the tropic is our language spoke
> And part of Flanders hath received our yoke.

But otherwise it does not fall beneath the poet's steady level.

Upon the Restoration Waller hastened to express his joy, mingled with trembling, "Upon His Majesty's Happy Return," and found little difficulty in making his peace. He met the king's complaint that his congratulation was inferior to his panegyric on the Protector with the famous retort, "Poets, Sire, succeed better in fiction than in truth." He was soon on such terms with Charles that he applied for the provostship of Eton; the king agreed, but Clarendon refused, on the ground that he was a layman, and the refusal was sustained by the council. He thus failed in his only application for substantial evidence of the king's favor, but in every other respect the changed state of things made his old age happy and glorious. He entered parliament again, and became, Burnet says, "the delight of the House, and, though old, said the liveliest things of any of them." His witty sayings were circulated through the town, and, as Johnson suspects, good things were fathered on him,—a tribute to his reputation. Although a water-drinker, he was a boon companion with the roystering wits, Dorset saying that "no man in England should sit in his company without drinking, except Ned Waller." Further, surviving all his early contemporaries, he found himself in higher reputation than ever as a poet. His poems now went through several editions, each increased by new productions, though the bulk was never large. He wrote in his formed eulogistic fashion on topics of the day, on St. James's Park, on Somerset House, the victory over the Dutch, the queen's birthday, the beauties, and other celebrities of the time. He fitted *The Maid's Tragedy* with a happier ending in rhymed couplets, assisted Dorset and Godolphin in the translation of the *Pompey* of Corneille, and wound up his career becomingly with *Divine Poems*, continuing to write to the last. He died in 1687, at the age of eighty-two, and at the height of his poetic reputation. Rymer of the *Fœdera*, the savage critic of Shakespeare, wrote the epitaph for his tomb at Beaconsfield, in which it is recorded that "inter poetas sui temporis facile princeps, lauream, quam meruit adolescens, octogenarius haud abdicavit." Fenton, Pope's coadjutor in the translation of the *Odyssey*, edited and commented on his poems after his death, justifying the pains bestowed by comparing him to Petrarch and Malherbe.

There can be no doubt that as a panegyrical poet, ready to overlay any subject, entirely irrespective of its intrinsic worth with a cleverly woven and tastefully colored garment of words and images, Waller deserved all the admiration he received, and would be hard to beat in our literature. Fenton showed true discernment in urging that his excellence lay in commendation, whether or not he was right in adding that any ill-natured person could be a satirist. And complimentary poetry was so much in fashion when poets were courted and munificently rewarded by politicians that Waller's fame from the Restoration till the time of Walpole, who dispensed with the aid of complimentary poets, is easy to understand. But Mr. Gosse's recent contention that Waller must be regarded as the founder of the classical school, and that his influence changed the course of our literature for a century, must pass as a hurried exaggeration. He was so eminently successful that he influenced minor poets at the close of his life and for generations afterwards, but his range of subjects as well as his art was extremely limited, and much larger and wider influences were at work. He is an example of one of the tendencies, but it is absurd to represent him as a commanding influence, except in a very humble field. He influenced panegyrical writing, and, inasmuch as this fell in with and influenced the tendency "to dress nature to advantage," "to raise sentiments above the vulgar pitch" with the borrowed riches of genuinely impassioned poetry, it might be argued that Waller's influence extended beyond his own narrow circleof aims. But his effect on Dryden or on Pope was infinitesimal. Even on the form of the favorite "classical" couplet Waller's single example cannot be held to have told in any considerable degree. It was already an established form for complimentary verse when he began to write. "Waller was smooth," it is true, but Pope at once qualifies the compliment with a reference to his want of variety. And Pope is also strictly correct in confining Waller's metrical improvements to his post-Restoration verse. When we place Waller's later couplets side by side with his earlier, say *The Triple Combat* or *The Divine Poems*, with *His Majesty's Escape*, or *The Countess of*

Carlisle in Mourning, or *The Death of Lady Rich*, we become aware of a marked change in his metrical scheme, notwithstanding the current opinion to the contrary. It is only in his later couplets that he aims, under French influence, as Pope justly implies, at making each distich complete in itself, varying this only with a stave of four, generally with a break in the third line. His earlier couplets are less monotonous, and were obviously modelled on the *Hero and Leander* of Marlowe and Chapman. To that noble poem, indeed, which was not known in the days when Waller's rhythm was so admired, he owed a large part of his panegyrical stock-in-trade, as anybody familiar with it can trace, not merely in his "classical" allusions, but also in his diction and his earlier metre. As regards smoothness and balance, there are no couplets in the edition of 1645 that could not be paralleled from the verses of his contemporaries, George Sandys and Cowley. (W. M.)

WALLIS, John (1616–1703), an eminent English mathematician, logician, and grammarian, was born on the 23d November, 1616 at Ashford, in Kent, of which parish his father was then incumbent. Having been previously instructed in Latin, Greek, and Hebrew, he was in 1632 sent to Emmanuel College, Cambridge, and afterwards was chosen fellow of Queen's College. Having been admitted to holy orders he left the university in 1641 to act as chaplain to Sir William Darley, and in the following year accepted a similar appointment from the widow of Sir Horatio Vere. It was about this period that he displayed surprising talents in deciphering the intercepted letters and papers of the Royalists. His adherence to the Parliamentary party was in 1643 rewarded by the living of St. Gabriel, Fenchurch Street, London. In 1644 he was appointed one of the scribes or secretaries of the Assembly of Divines at Westminster. During the same year he married Susanna Glyde, and thus vacated his fellowship; but the death of his mother had left him in possession of a handsome fortune. In 1645 he attended those scientific meetings which led to the establishment of the Royal Society. When the Independents obtained the superiority, Wallis adhered to the Solemn League and Covenant. The living of St. Gabriel he exchanged for that of St. Martin, Ironmonger Lane; and, as rector of that parish, he in 1648 subscribed the Remonstrance against putting Charles I. to death. Notwithstanding this act of opposition, he was in June, 1649, appointed Savilian professor of geometry at Oxford. In 1654 he there took the degree of D.D., and four years later succeeded Dr. Langbaine as keeper of the archives. After the Restoration he was named one of the king's chaplains in ordinary. While complying with the terms of the Act of Uniformity, Wallis seems always to have retained moderate and rational notions of ecclesiastical polity. He died at Oxford on the 28th of October, 1703, in the eighty-seventh year of his age.

The works of Wallis are numerous, and relate to a multiplicity of subjects. His *Institutio Logicæ*, published in 1687, was very popular, and in his *Grammatica Linguæ Anglicanæ* we find indications of an acute and philosophic intellect. The mathematical works are published some of them in a small 4to volume, Oxford, 1657, and a complete collection in three thick folio volumes, Oxford, 1695–93–99. The third volume includes, however, some theological treatises, and the first part of it is occupied with editions of treatises on harmonics and other works of Greek geometers, some of them first editions from the MSS., and in general with Latin versions and notes (Ptolemy, Porphyrius, Briennius, Archimedes, Eutocius, Aristarchus, and Pappus). The second and third volumes include also two collections of letters to and from Brounker, Frenicle, Leibnitz, Newton, Oldenburg, Schooten, and others; and there is a tract on trigonometry by Caswell. Excluding all these, the mathematical works contained in the first and second volumes occupy about 1800 pages. The titles in the order adopted, but with date of publication, are as follows: "Oratio Inauguralis," on his appointment (1649) as Savilian professor, 1657; "Mathesis Universalis, seu Opus Arithmeticum Philologice et Mathematice Traditum, Arithmeticam Numerosam et Speciosam Aliaque Continens," 1657; "Adversus Meibomium, de Proportionibus Dialogus," 1657; "De Sectionibus Conicis Nova Methodo Expositis," 1655; "Arithmetica Infinitorum, sive Nova Methodus Inquirendi in Curvilineorum Quadraturam Aliaque Difficiliora Matheseos Problemata," 1655; "Eclipsis Solaris Observatio Oxonii Habita 2d Aug. 1654," 1655; "Tractatus Duo, prior de Cycloide, posterior de Cissoide et de Curvarum tum Linearum Εὐθύνσει tum superficierum Πλατυσμῶ," 1659; "Mechanica, sive de Motu Tractatus Geometricus," three parts, 1669–70–71; "De Algebra Tractatus Historicus et Practicus, ejusdem originem et progressus varios ostendens," English, 1685; "De Combinationibus Alternationibus et Partibus Aliquotis Tractatus," English, 1685; "De Sectionibus Angularibus Tractatus," English, 1685; "De Angulo Contactus et Semicirculi Tractatus," 1656; "Ejusdem Tractatus Defensio," 1685; "De Postulato Quinto, et Quinta Definitione, Lib. VI. Euclidis, Disceptatio Geometrica," ? 1663; "Cuno-Cuneus, seu Corpus partim Conum partim Cuneum Representans Geometrice Consideratum," English, 1685; "De Gravitate et Gravitatione Disquisitio Geometrica," 1662 (English, 1674); "De Æstu Maris Hypothesis Nova," 1666–69.

The *Arithmetica Infinitorum* relates chiefly to the quadrature of curves by the so-called method of indivisibles established by Cavalleri, 1629, and cultivated in the interval by him, Fermat, Descartes, and Roberval. The method is substantially that of the integral calculus; thus, *e.g.*, for the curve $y = x^2$ to find the area from $x = 0$ to $x = 1$, the base is divided into n equal parts, and the area is obtained as $= \frac{1}{n^3}(1^2 + 2^2 \ldots + n^2)$, $= \frac{1}{6n^3}n(n+1)(2n+1)$, which, taking n indefinitely large, is $= \frac{1}{3}$. The case of the general parabola $y = x^m$(m a positive integer or fraction), where the area is $\frac{1}{m+1}$, had been previously solved. Wallis made the important remark that the reciprocal of such a power of x could be regarded as a power with a negative exponent $\left(\frac{1}{x^m} = x^{-m}\right)$, and he was thus enabled to extend the theorem to certain hyperbolic curves, but the case m a negative value larger than 1 presented a difficulty which he did not succeed in overcoming. It should be noticed that Wallis, although not using the notation x^m in the case of a positive or negative fractional value, nor indeed in the case of a negative integer value of m, deals continually with such powers, and speaks of the positive or negative integer or fractional value of m as the index of the power. The area of a curve, $y =$ sum of a finite number of terms Ax^m, was at once obtained from that for the case of a single term; and Wallis, after thus establishing the several results which would now be written $\int_0^1 (x - x^2)^0 dx = 1$, $\int_0^1 (x - x^2)^1 dx = \frac{1}{6}$, $\int_0^1 (x - x^2)^2 dx = \frac{1}{30}$, $\int_0^1 (x - x^2)^3 dx = \frac{1}{140}$, etc., proposed to himself to interpolate from these the value of $\int_0^1 (x - x^2)^{\frac{1}{2}} dx$, which is the expression for the area $(= \frac{1}{8}\pi)$ of a semicircle, diameter $= 1$; making a slight transformation, the actual problem was to find the value of $\square\left(= \frac{4}{\pi}\right)$, the term halfway between 1 and 2, in the series of terms, 1, 2, 6, 20, 70, . . .; and he thus obtained the remarkable expression $\pi = \frac{2.4.4.6.6.8.8\ldots}{3.3.5.5.7.7.9\ldots}$, together with a succession of superior and inferior limits for the number π.

In the same work Wallis obtained the expression which would now be written $ds = dx\sqrt{1 + \left(\frac{dy}{dx}\right)^2}$ for the length of the element of a curve, thus reducing the problem of rectification to that of quadrature. An application of this formula to an algebraical curve was first made a few years later by W. Neil; the investigation is reproduced in the "Tractatus de Cissoide, etc." (1659, as above), and Wallis adds the remark that the curve thus rectified is in fact the semicubical parabola.

The *Mathesis Universalis* is a more elementary work intended for learners. It contains copious dissertations on fundamental points of algebra, arithmetic, and geometry, and critical remarks.

The *De Algebra Tractatus* contains (chapters 66–69) the idea of the interpretation of imaginary quantities in geometry. This is given somewhat as follows: the distance represented by the square root of a negative quantity cannot be measured in the line backwards or forwards, but can be measured in the same plane above the line, or (as appears elsewhere) at right angles to the line either in the plane, or in the plane at right angles thereto. Considered as a history of algebra, this work is strongly objected to by Montucla on the ground of its unfairness as against the early Italian algebraists and also Vieta and Descartes, and in favor of

Harriot; but De Morgan, while admitting this, attributes to it considerable merit.

The two treatises on the cycloid and on the cissoid, etc., and the *Mechanica* contain many results which were then new and valuable. The latter work contains elaborate investigations in regard to the centre of gravity, and it is remarkable also for the employment of the principle of virtual velocities. The cuno-cuneus is a highly interesting surface; it is a ruled quartic surface, the equation of which may be written $c^2y^2 = (c - z)^2(a^2 - x^2)$.

Among the letters in volume iii., we have one to the editor of the Leipsic *Acts*, giving the decipherment of two letters in secret characters. The ciphers are different, but on the same principle: the characters in each are either single digits or combinations of two or three digits, standing some of them for letters, others for syllables or words,—the number of distinct characters which had to be deciphered being thus very considerable.

For the prolonged conflict between Hobbes and Wallis, see HOBBES, vol. xii. pp. 39–40. (A. CA.)

WALLON, or **WALLOON**, the collective name of the inhabitants of the southeastern division of Belgium, who are distinguished from the rest of the population chiefly by their Romance speech and darker complexion. The Wallon domain comprises the four provinces of Hainault, Namur, Liége, and Luxemburg, besides about one-third of Brabant. It forms a nearly regular right-angled triangle, with apex at Maestricht within the Dutch frontier, and base stretching along the French frontier in a southeasterly direction, from the neighborhood of Lille to Longwy at the southwest corner of German Luxemburg. It coincides almost exactly with the section of the Meuse basin comprised within Belgian territory, and has a total area of 6000 square miles, or about one-half of the kingdom, with a population (1886) of 2,780,000, or considerably less than half of the entire Belgian population. But from the following figures it is evident that the Romance is steadily gaining on the Flemish (Teutonic) section and will soon be in a majority. In 1830 the Wallon population numbered 1,360,000 as against 1,860,000 Flemish; in 1866 the corresponding figures were 2,040,000 and 2,406,000; and in 1886 they were 2,780,000 and 3,060,000.

This northeastern extremity of ancient Gaul, originally inhabited by the Aduatici, Eburones, Tungri, and other Belgic nations, was reduced by Cæsar (51 B.C.), and early brought within the sphere of Roman culture. Hence the Latin language was already too firmly established to be supplanted by the Teutonic when the country was occupied in the 5th century by the Franks previous to their conquest of the more central provinces. But about the same time Roman institutions and speech were entirely supplanted in the more open low-lying districts of western Belgium by the same Franks penetrating from the east, and by the roving Saxon and Frisian tribes arriving by sea on the *Litus Saxonicum*. Since that time the two elements have remained, without much further change, in close proximity, or separated only by intervening strips of "marches" or borderlands formed by the uncleared forest formerly known as the *Silva Carbonaria*.

The Wallons, allowing for inevitable intermingling, especially towards the German frontier, are thus Romanized Gauls, lineal representatives of the ancient Belgæ, in a much truer sense than their Flemish neighbors, although accepting from them this name of "Wallon," that is, *Welsh* or *Foreign*, just as the Saxon intruders in Britain imposed the same designation on its primitive inhabitants. Their Gallic descent is shown specially in their much darker complexion, as clearly established by the anthropological statistics collected by Dr. Beddoe.[1] In other respects the Wallons contrast favorably with the Teutonic-speaking populations of Belgium. They are physically a stronger race, more bony, angular, and taller, and also more long-lived and exempt from disease, as shown by the much lower death-rate in the province of Namur (18 per 1000) than in West Flanders (25 per 1000). The cause of this superiority has been attributed by some writers to a greater inherent vitality of the Wallons, but by others with more probability to their greater general comfort, and particularly to the more salubrious climate of their elevated and more hilly territory. In mediæval times the Flemings were certainly far superior in wealth, culture, and public spirit. But the great centres of industry have since been shifted from Bruges and Ghent (Flanders) to Liége and Namur, and the Wallons now take the lead in all these respects,—in fact, in everything except music, painting, and the fine arts generally.

The Wallon language is a very marked dialect of the Langue d'Oïl (Northern French), betraying strong affinities to the neighboring idioms of Picardy and Lorraine, but still distinct from both. Being little cultivated, and possessing no literary standard, it has developed several varieties, the chief of which are—(1) the *Liégcois*, current throughout the districts bordering on Rhenish Prussia, and largely affected by German influences; (2) the *Namurois* of the central districts and the Ardennes, with several local patois; (3) the *Hennuyer* of Hainault and the western districts, so named from the town of Hennuyères, where it is spoken with the greatest purity. But since French has been accepted as the written standard and the official language of the whole kingdom Wallon is gradually receding from the large towns and assuming more and more the character of a purely rural patois. It possesses no literary remains of any consequence, and its earliest extant monument appears to be the "Declaration des Provost, Juret, Eskievin de Valenchienes" of the year 1256.

WALLSEND, a town of Northumberland, England, on the north bank of the Tyne and on the Newcastle and Tynemouth Railway, 4 miles east-northeast of Newcastle. The church of St. Peter, erected in 1809 at a cost of £5000 [$24,300] has a tower surmounted by a spire. There are still some remains of the old church of the 11th century in the Transition Norman style. The church of St. Luke was erected in 1886 at a cost of £4000 [$19,440]. At an early period Wallsend was famous for its coals, but the name has now a general application to coal that does not go through a sieve with meshes ⅝ths of an inch in size. The colliery, which was opened in 1807, has frequently been the scene of dreadful accidents. There are also ship and boat building yards, engineering works, lead and copper smelting works, cement works, and brick and tile works. The ecclesiastical commissioners are lords of the manor. The town is governed by a local board of twelve members. The population of the urban sanitary district (area 1202 acres) in 1871 was 4169, and in 1881 it was 6351.

Wallsend derives its modern name from its position at the extremity of HADRIAN'S WALL (*q.v.*); originally it was the Roman station *Segedunum*. It had a quay, of which remains have been discovered, and possessed a magazine of corn and other provisions for the supply of the stations in the interior.

WALNUT (*Juglans*), a genus of seven or eight species, natives of the temperate regions of the northern hemisphere, some even extending into Mexico and the West Indies. They are all trees, usually of large size, with alternate, stalked, unequally pinnate leaves, and abounding in an aromatic resinous juice. The scars left by the fallen leaves are unusually large and prominent. The buds are not unlike those of the ash; and it frequently happens that in the axils of the leaves, instead of one, several buds may be formed. The utility of this is seen in seasons when the shoot produced from the first bud is killed by frost; then one of the supplementary buds starts into growth, and thus replaces the injured shoot. The flowers are unisexual and monœcious, the numerous males borne in thick catkins proceeding from the side of last year's shoot. The female flowers are solitary or few in number, and borne on short terminal spikes of the present season's growth. In the male flower the receptacle is "concrescent" or inseparate from the bract in whose axil it originates. The receptacle is, in consequence, extended more or less horizontally, so that the flowers appear to be placed on the upper surface of horizontally-spreading stalks. The perianth consists of five or six oblong greenish lobes, within which is found a tuft, consisting of a large number of stamens, each of which has a very short filament and an oblong two-lobed anther bursting longitudinally, and surmounted by an oblong lobe, which is the projecting end of the connective. There is usually no trace of ovary in the male flowers, though by exception one may occasionally be formed.

---

[1] In Namur, a central point of the Wallon domain, the proportion of dark eyes is 47 and of dark hair 57.5 per cent., as compared with 24 and 20 respectively in Mechlin, a corresponding central point in the Flemish domain.

The female flower consists of a cup-like receptacle, inseparate from the ovary, and bearing at its upper part a bract and two bracteoles, uplifted with the receptacle. From the margin of this latter organ springs a perianth of four short lobes. The one-celled ovary is immersed within the receptacular tube, and is surmounted by a short style with two short ribbon-like stigmatic branches. The solitary ovule springs erect from the base of the ovarian cavity. The fruit is a kind of drupe, the fleshy husk of which is the dilated receptacular tube, while the two-valved stone represents the two carpels. The solitary seed has no perisperm or albumen, but has two large and curiously crumpled cotyledons concealing the plumule, the leaves of which, even at this early stage, show traces of pinnæ.

The species best known is *J. Regia*, the Common Walnut, a native of the mountains of Greece, of Armenia, of Afghanistan and the northwest Himalayas, and also found in Japan. Traces of the former existence of this or of a very closely allied species are found in the Post-Tertiary deposits of Provence and elsewhere, proving the former much wider extension of the species. At the present day the tree is largely cultivated in most temperate countries for the sake of its timber or for its edible nuts. The timber is specially valued for cabinet work and for gunstocks, the beauty of its markings rendering it desirable for the first-named purpose, while its strength and elasticity fit it for the second. The leaves and husk of the fruit are resinous and astringent, and are sometimes used medicinally as well as for dyeing purposes. It is stated that sugar is prepared from the sap in a similar manner to that obtained from the maple *Acer saccharinum* in Canada. The young fruits are used for pickling. When ripe the seeds are much esteemed as a delicacy, while in France much oil of fine quality is extracted from them by pressure. There are several varieties in cultivation, varying in the degree of hardihood, time of ripening, thickness of shell, size, and other particulars. In the climate of Great Britain a late variety is preferable. as securing the young shoots against injury from frost, to which otherwise they are very subject. The kernel of the large-fruited variety is of very indifferent quality, but its large shells are made use of by the French as trinket-cases.

Among the American species *J. nigra*, the Black Walnut, is especially noteworthy as a very handsome tree, whose timber is of great value for furniture purposes, but which is now becoming scarce. In Britain it forms a magnificent tree. The White Walnut, *J. cinerea*, is a smaller tree; its leaves are used medicinally.

Closely allied to the walnuts and sometimes confounded with them are the hickories (see HICKORY). See also vol. xii. p. 289.

WALPOLE, HORACE (1717–1797), who was born on 24th September, 1717, was accepted and recognized throughout his life as the youngest of the six children of Sir Robert Walpole by Catherine Shorter, but by some of the scandal-mongers of a later age, Carr, Lord Hervey, the half-brother of the peer who wrote the *Memoirs of the Court of George the Second*, has been called his father. This parentage has been assigned to him partly through the circumstance that the first wife of Sir Robert Walpole lived for some time estranged from her husband and on terms of friendship with Carr, Lord Hervey, not the least clever or unprincipled member of a family notorious for ability and for laxity of morals, and partly through the antagonism of the qualities shown by Horace Walpole to those of the prime minister, and through their affinity with the talents of the Herveys. If this rumor be correct, no such suspicion ever entered into the mind of Horace Walpole. To his mother he erected a monument, with an inscription couched in terms of sincere affection, in the chapel of Henry VII. in Westminster Abbey, and from the beginning to the end of his life his sarcasms never spared the Newcastles and the Hardwickes, who had shown, as he thought, lukewarmness in support of his father's ministry. About 1728 he was sent to Eton, and in 1735 matriculated at King's College, Cambridge. Two years (1739–41) were spent in the recognized grand tour of France and Italy, in company with Gray the poet, whose acquaintance had been made amid the classic groves of Eton and Cambridge. They stopped a few weeks in Paris, and lingered for three months under the shadow of the magnificent portals of the cathedral of Rheims, on the pretence of learning the French language. Henry Seymour Conway, whose mother was a sister of Lady Walpole, shared their society in the French city, and retained Horace Walpole's warm friendship during life. The other two members of this little circle next proceeded to Florence, where Walpole rested for more than a year in the villa of Horace Mann, the British envoy-extraordinary for forty-six years to the court of Tuscany. Mann's family had long been on terms of the closest intimacy with his guests, as Robert Mann was concerned in the contract for which Sir Robert Walpole was expelled from the House of Commons in 1712, and the envoy continued the correspondent of Walpole until 1786, for as they never met again their friendship remained unbroken. At Reggio Walpole and Gray parted in resentment. The latter was shy in manners and absorbed in literature, while his more opulent companion lived in society, and only dabbled in antiquities for pleasure's sake. Walpole in after years took the blame of these differences on himself, and it is generally believed that the quarrel arose from his laying too much stress on his superiority in position. In 1744 the two friends were nominally reconciled, but the breach was not cemented.

During Walpole's absence he was returned to parliament in 1741 for the Cornish borough of Callington over which his elder brother, through his marriage with the heiress of the Rolles, exercised supreme influence. He represented three constituencies in succession, Callington 1741–54, the family borough of Castle Rising from 1754 to 1757, and the more important constituency of King's Lynn, for which his father had long sat in parliament, from the latter date until 1768. In that year he retired, probably because his success in political life had not equalled his expectations, but he continued until the end of his days to follow and to chronicle the acts and the speeches of both Houses of Parliament. Through his father's influence he had obtained three lucrative sinecures producing at least £5000 [$24,300] a year and for many years (1745–84) he enjoyed a share, estimated at about £1500 [$7290] a year, of a second family perquisite, the collectorship of customs. The possession of these ample endowments and of a leasehold house in Arlington Street, which was left to him by his father, enabled him, a bachelor all his days, to gratify every expensive luxury and every costly taste. He purchased in 1747 the charmingly situated villa of Strawberry Hill, near Twickenham, on the banks of the Thames, and six years later began a series of alterations in the Gothic style, not completed for nearly a quarter of a century later, under which the original cottage became transformed into a building without parallel in Europe. Some years after this purchase he established a printing-press there for the gratification of his literary tastes, and many of the first editions of his own works were struck off within its walls. At this press were produced in 1753 the clever, if eccentric, designs of Richard Bentley (the youngest child of the great doctor, and for some time a protegé of Horace Walpole) for the poems of Gray; and among the reprints of Strawberry Hill were the *Life of Lord Herbert of Cherbury*, *Memoirs of Grammont*, Hentzner's *Journey into England*, and Lord Whitworth's *Account of Russia*. The rooms of this whimsical edifice were crowded with curiosities of every description, and the house and its contents were shown, by tickets to admit four persons, between 12 and 3 from May to October, but only one party was admitted on each day, and the owner, although enamored of notoriety, simulated discontent at this limited intrusion into his privacy. His nephew, the reckless third earl, died in 1791, and Horace succeeded to the peerage, but he never took his place in the House of Lords, and sometimes signed his name as "the uncle of the late earl of Orford." All his life long he was the victim of the gout, but he lived to extreme old age, and died unmarried, in Berkeley Square, London, March 2, 1797, when his body was buried privately at Houghton. The ancient estate of the family descended to the earl of Cholmondeley, whose ancestor had married Horace Walpole's younger sister. All Walpole's printed books and manuscripts were left to Robert Berry and his two daughters, Mary and Agnes; their friendship had been very dear to the declining days of Walpole, who, it has even been said, wished to marry Mary Berry. By his will each of the ladies obtained a pecuniary legacy of £4000 [$19,440], and for their lives the house and garden, formerly the abode of Kitty Clive, which adjoined Strawberry Hill. Strawberry Hill went to Mrs. Anne Damer, daughter of his lifelong friend General Conway, for her life, but it was entailed on the countess dowager of Waldegrave and her heirs. Walpole died worth £91,000 [$442,260] in the three per cents, and gave the whole of it away, the chief legacy being £10,000 [$48,600] for his niece the duchess of Gloucester. The collections of Strawberry Hill, which he had spent nearly fifty years in amassing, were dispersed under the hammer of George Robins in 1842. They are described in a catalogue of that date, and in a series of articles in the *Gentleman's Magazine* for that year.

The pen was ever in Horace Walpole's hands, and his entire compositions would fill many volumes. His two works of imagination, the romance of the *Castle of Otranto* and the tragedy of the *Mysterious Mother*, are now all but forgotten. The former, which purported to be a story translated by William Marshall, gent., from the original Italian of Onuphrio Muralto, canon of the church of St. Nicholas at Otranto, was often reprinted in England, and was translated into both French and Italian. By Sir Walter Scott it was lauded to the skies for its power in raising the passions of fear and pity; from Hazlitt it met with intense condemnation. The *Mysterious Mother*, a tragedy too horrible for representation on any stage, was never intended for performance in public, and only fifty copies of it were printed at Strawberry Hill. By Byron, who, like Horace Walpole, affected extreme liberalism, and like him never forgot that he was born within the purple, this tragedy was pronounced "of the highest order." Several of Walpole's antiquarian works merit high praise. The volume of *Historic Doubts on the Life and Reign of King Richard the Third*, one of the earliest attempts to rehabilitate a character previously stamped with infamy, showed acuteness and research. These doubts provoked several answers, which are criticised in a supplement edited by Dr. Hawtrey for the Philobiblon Society. A work of more lasting reputation, which has retained its vitality for more than a century, is entitled *Anecdotes of Painting in England, with some Account of the Principal Artists; collected by George Vertue, and now digested and published from his original manuscripts by Horace Walpole* (4 vols., 1762–71). Its value to art students and to admirers of biographical literature demanded its frequent reproduction, and it had the good fortune to be re-edited with additions by the Rev. James Dallaway in five volumes (1826–28), and then again was revised and edited by R. N. Wornum in 1849. A cognate volume, also based on the materials of Vertue, is entitled the *Catalogue of Engravers Born and Resident in England*, which, like its more famous predecessor, often passed through the press. On the *Catalogue of Royal and Noble Authors of England* Walpole, whose professed liberalism only stopped short of the principles of republicanism, spent many hours of toilsome research. The best edition is that which appeared in five volumes, in 1806, under the competent editorship of Thomas Park, who carefully verified and diligently augmented the labors of the original author. As a senator himself, or as a private person following at a distance the combats at St. Stephen's, Walpole recorded in a diary the chief incidents in English politics. For twenty-seven years he studied, a silent spectator for the most part, the characters of the chief personages who trod the stage of politics, and when he quitted the scene he retained the acquaintance of many of the chief actors. If he was sometimes prejudiced, he rarely distorted the acts of those whom he disliked, and his prejudices, which lie on the surface, were mainly against those whom he considered the traitors of his father. These diaries extend from 1750 to 1783, and cover a period of momentous importance in the annals of the national history. The *Memoirs of the Last Ten Years of the Reign of George II.* was edited by Lord Holland; its successor, *Memoirs of the Reign of King George III.*, was published under the editorial care of Sir Denis Le Marchant, who poured into his annotations a vast store of information; the last volumes of the series, *Journal of the Reign of George III. from* 1771 *to* 1783, were edited and illustrated by Doran; and to these works should be added the *Reminiscences*, which Walpole wrote in 1788 for the gratification of the Misses Berry. These labors would in themselves have rendered the name of Horace Walpole famous for all time, but his delightful *Letters* are the crowning glory of his life. His correspondents were numerous and widespread, but the chief of them were Cole the clerical antiquary of Milton, Robert Jephson, an obscure play-writer in Ireland, Mason the poet, Lord Hertford during his embassy in Paris, the countess of Ossory, Lord Harcourt, George Montagu, one of his earliest friends, Conway, and Sir Horace Mann. With most of these friends he quarrelled, but the friendship of the last two, in the former case through genuine liking, and in the latter through his fortunate absence from England, was never interrupted. The *Letters* were published at different dates, but the standard collection is that by Peter Cunningham (9 vols., 1857–59), and to it should be added the volumes of the letters addressed to Walpole by his old friend Madame du Deffand (1810, 4 vols.), and the publication of Dr. Doran, *Mann and Manners at the Court of Florence*, which is founded on the epistles sent in return to Walpole by the envoy-extraordinary. A handsome little volume, *Horace Walpole and his World*, consisting of select passages from his letters, extracted and strung together in a simple narrative by Mr. L. B. Seeley, was issued in 1884. Walpole has been called "the best letter-writer in the English language"; and few indeed are the names, possibly none save Swift and Cowper, which can compare with his. In these compositions his very foibles are penned for our amusement, and his love of trifles—for, in the words of another Horace, he was ever "nescio quid meditans nugarum et totus in illis"—minister to our instruction. To these friends he communicated every fashionable scandal, every social event, and the details of every political struggle in English life. The politicians and the courtiers of his day were more akin to his character than were the chief authors of his age, and the weakness of his intellectual perceptions stands out most prominently in his estimates of such writers as Johnson and Goldsmith, Gibbon and Hume. On many occasions he displayed great liberality of disposition, and he bitterly deplored for the rest of his days his neglect of the unhappy Chatterton.

Abundant information about Horace Walpole will be found in the *Memoirs* of him and of his contemporaries edited by Eliot Warburton, Jesse's *George Selwyn and his Contemporaries*, and the extracts from the journals and correspondence of Miss Berry; and it would be unpardonable to omit mention of Macaulay's sketch of Walpole's life and character. (W. P. C.)

WALPOLE, Sir Robert, Earl of Orford (1676–1745), prime minister of England from 1721 to 1742, was the third but eldest surviving son of Robert Walpole, M.P., of Houghton in Norfolk,[1] by Mary, only daughter and heiress of Sir Jeffery Burwell, of Rougham, in Suffolk. The father, a jolly old squire who revelled in outdoor sport and the pleasures of the table, transmitted to his son the chief traits in his own character. The future statesman was born at Houghton on 26th August, 1676, and was sent to Eton and to King's College, Cambridge, where he was admitted as scholar on 22d April, 1696. At this time he was destined, as a younger son, for the church, but his two elder brothers died young and he became the heir to an estate producing about £2000 a year, whereupon in May, 1698, he resigned his fellowship, and was soon afterwards withdrawn by his father from the university. His education lasted sufficiently long, however, to enable him to gratify the tastes of the county members in parliament with the usual quotations from Horace, though in classical attainments he was excelled by Pulteney, Carteret, and many others of his contemporaries in politics. On his father's decease the electors of the family borough of Castle Rising returned him in January, 1701, to the House of Commons as their representative, but after two short-lived parliaments he sought the suffrages of the more important constituency of King's Lynn (1702), and was elected as its member at every subsequent dissolution until he left the Lower House. From the first he took a keen interest in the business of the House, and not many months passed away before his shrewdness in counsel and his zeal for the interests of the Whigs were generally recognized. In March, 1705, according to the statement of Archdeacon Coxe, he was appointed one of the council to Prince George of Denmark, the inactive husband of Queen Anne, and then lord high admiral of England. Complaints against the administration of the navy were then loud and frequent (Burton's *Queen Anne*, ii. 22–31), and the responsibilities of his new position tested his capacity for public life. His abilities proved equal to the occasion, and justified his advancement, in succession to his life-long rival Henry St. John, to the more important position of secretary-at-war (February, 1708), an office of recent creation but in time of war of great responsibility, which brought him into immediate contact with the duke of Marlborough and the queen. With this post he held for a short time (1710) the treasurership of the navy, and by the discharge of his official duties and by his skill in debate became admitted to the inmost councils of the ministry. He could not succeed, however, in diverting Godolphin from the great error of that statesman's career, the impeachment of Sacheverell, and when the committee was appointed for elaborating the articles of impeachment Walpole was called upon to act as one of the managers for the House of Commons. On the wreck of the Whig party which ensued upon this fatal mistake, Walpole shared in the general misfortune, but neither cajolery nor menace could induce him to retain office, and he took his place with his friends in opposition. His energies now shone forth with irresistible vigor; both in debate and in the pamphlet press he took up the cause of the ejected ministry, and in revenge for his zeal his political opponents brought against him an accusation of personal corruption. On these charges, now universally acknowledged to have proceeded from party animosity, he was in the spring of 1712 expelled from the House and committed to the Tower. His prison cell now became the rendezvous of the Whigs among the aristocracy, while the populace heard his praises commemorated in the ballads of the streets. The ignominy which the Tories had endeavored to inflict upon him was turned into augmented reputation. At the dissolution of 1713 the faithful electors of King's Lynn again placed their trust in him, and during this parliament, the last summoned by Queen Anne, he took the leading part in defence of Steele against the attacks of the Tories.

---

[1] The head of a family whose ancestors and descendants are recorded in an elaborate pedigree published in the *Proceedings of the Norfolk and Norwich Archæol. Soc.*, i. 363–79.

With the accession of George, the Whigs regained their supremacy, and for nearly half a century they retained the control of English politics. The prizes fell to the victors, and Walpole obtained the lucrative if unimportant post of paymaster-general of the forces in the administration which was formed under the nominal rule of Lord Halifax, but of which Stanhope and Townshend were the guiding spirits. A committee of secrecy was appointed to inquire into the acts of the late ministry, and especially into the peace of Utrecht, and to Walpole was entrusted the place of chairman. Most of his colleagues in office were members of the House of Lords, and the lead in the Commons quickly became the reward of his talents and assiduity. Halifax died, and after a short interval Walpole was exalted into the conspicuous position of first lord of the treasury and chancellor of the exchequer (11th October, 1715). Jealousies, however, prevailed among the Whigs, and the German favorites of the new monarch quickly showed their discontent with the heads of the ministry. Townshend was forced into resigning his secretaryship of state for the dignified exile of viceroy of Ireland, but he never crossed the sea to Dublin, and the support which Sunderland and Stanhope, the new advisers of the king, received from him and from Walpole was so grudging that Townshend was dismissed from the lord-lieutenancy (April, 1717), and Walpole on the next morning withdrew from the ministry. They plunged into opposition with unflagging energy, and in resisting the measure by which it was proposed to limit the royal prerogative in the creation of peerages Walpole exerted all his powers. This display of ability brought about a partial reconciliation of the two parties among the Whigs. To Townshend was given the presidency of the council, and Walpole once again assumed the paymastership of the forces (June, 1720). On the financial crash which followed the failure of the South Sea scheme, the public voice insisted that he should assume a more prominent place in public life. At this crisis in England's fortunes Stanhope and Craggs were seized by death, Aislabie, the chancellor of the exchequer, was committed to the Tower, and Sunderland, though acquitted of corruption, was compelled to resign the lead. Walpole, as first lord of the treasury and chancellor of the exchequer (April, 1721), became with Townshend responsible for the country's government (though for some years they had to contend with the influence of Carteret), and during the rest of the reign of George I. they remained at the head of the ministry. The hopes of the Jacobites, which revived with these financial troubles, soon drooped in disappointment. Atterbury, their boldest leader, was exiled; Bolingbroke, in dismay at their feebleness, sued for pardon, and was permitted to return to his own country. The troubles which broke out in Ireland over Wood's patent for a copper coinage were allayed through the tact of Carteret, who had been banished as its lord lieutenant by his triumphant rivals. The Continent was still troubled with wars and rumors of wars, but a treaty between England, Prussia, and France was successfully effected at Hanover in 1725. England was kept free from warfare, and in the general prosperity which ensued Walpole basked in the royal favor. His eldest son was raised to the peerage as Baron Walpole (10th June, 1723), and he himself became a knight of the Bath in 1725, and was rewarded with the Garter in 1726. Next year the first King George died, and Walpole's enemies fondly believed that he would be driven from office, but their expectations were doomed to disappointment. The confidence which the old king had reposed in him was renewed by his successor, and in the person of Queen Caroline, the discreet ruler of her royal spouse, the second George, the Whig minister found a faithful and life-long friend. For three years he shared power with Townshend, but the jealous Walpole brooked no rival near the throne, and his brother-in-law withdrew from official life to the groves of Norfolk in May, 1730. Before and after that event the administration was based on two principles, sound finance at home and freedom from the intrigues and wars which raged abroad. On the Continent congresses and treaties were matters of annual arrangement, and if the work of the plenipotentiaries soon faded it was through their labors that England enjoyed many years of peace. Walpole's influence received a serious blow in 1733. The enormous frauds on the excise duties forced themselves on his attention, and he proposed some arrangements by which the income resulting to the national exchequer from the duties on wine and tobacco might be largely increased. His opponents fastened on these proposals with irresistible force, and so serious an agitation stirred the country that the ministerial measure was dropped amid general rejoicing. Several of his most active antagonists were dismissed from office or deprived of their regiments, but their spirit remained unquenched, and when Walpole met a new House of Commons in 1734 his supporters were far less numerous. The Gin Act of 1736, by which the tax on that drink was raised to an excessive amount, led to disorders in the suburbs of London; and the imprisonment of two notorious smugglers in the Tolbooth at Edinburgh resulted in those Porteous riots which have been rendered famous in the *Heart of Midlothian.* These events weakened his influence with large classes in England and Scotland, but his parliamentary supremacy remained unimpaired, and was illustrated in 1737 by his defeat of Sir John Barnard's plan for the reduction of the interest on the national debt, and by his passing of the Playhouse Act, under which the London theatres are still regulated. That year, however, heralded his fall from power. His constant friend Queen Caroline died, and the prince of Wales, long discontented with his parents and their minister, flung himself into active opposition. Many of the boroughs within the limits of the duchy of Cornwall were obedient to the prince's will, and he quickly attracted to his cause a considerable number of adherents, of whom Pitt and the Grenvilles were the most influential. The leading orators of England thundered against Walpole in the senate, and the press resounded with the taunts of the poet and pamphleteer, illustrious and obscure, who found abundant food for their invectives in the troubles with Spain over its exclusive pretensions to the continent of America and its claim to the right of searching English vessels. The minister long resisted the pressure of the opposition for war, but at the close of 1739 he abandoned his efforts to stem the current, and with a divided cabinet was forced, as the king would not allow him to resign, into hostility with Spain. The Tory minority had seceded from parliament, but at the commencement of the session, in November, 1739, they returned to their places with redoubled energies. The campaign was prosecuted with vigor, but the successes of the troops brought little strength to Walpole's declining popularity, and when parliament was dissolved in April, 1741, his influence with his fellow-countrymen had faded away. His enemies were active in opposition, while some of his colleagues were lukewarm in support. In the new House of Commons political parties were almost evenly balanced. Their strength was tried immediately on the opening of parliament. The Bossiney election went against him by six votes; a member of the opposition was elected as chairman of committees by a majority of four; and the ministry was twice defeated over the Westminster election. The voting on the return for Chippenham was accepted as a decisive test of parties, and, as Walpole was beaten on a preliminary point in connection with the return, he resolved upon resigning his places. On the 9th of February, 1742, he was created earl of Orford, and two days later he ceased to be prime minister. A committee of inquiry into the conduct of his ministry for the previous ten years was ultimately granted, but its deliberations ended in nought, and Walpole was allowed to spend the rest of his days in retirement at Houghton. There he died 18th March, 1745, and in its parish church he was buried on March 25. With the permanent places, valued at £15,000 [$72,900] per annum, which he had secured for his family, and with his accumulations in office, he had rebuilt the mansion at great expense, and formed a gallery of pictures within its walls at a cost of £40,000 [$194,400], but the collection was sold by his grandson for a much larger sum in 1779 to the empress of Russia, and the estate and house of Houghton, a vast and gloomy edifice described in the *Art Journal* for March, 1887, passed to Lord Cholmondeley, the third earl having married the premier's younger daughter. Walpole was twice married,—in 1700 to Catherine, eldest daughter of John Shorter, who died in 1737, having had issue three sons and two daughters, and in 1738 to Maria, daughter of Thomas Skerret, a lady often mentioned in the letters of Lady Mary Wortley Montague.

Civil wars at home and the protracted struggle with France on the Continent had produced in Englishmen an intense desire for peace, and, in their remembrance of the constant disputes under the previous two sovereigns over the succession to the throne, the great majority of them cheerfully consented to the rule of the electors of Hanover. Walpole knew the disposition of his countrymen, and he gratified their tastes by consistently acting both in ecclesiastical and civil affairs on the principle *quieta non movere.* He had profited by the lesson of the ill-fated prosecution of Sacheverell, and while he was prime minister the Church of England slept in peace without fear of danger from her enemies. The followers of dissent ranged themselves behind his banner, but they were fed by promises rather than by actual concessions, and the wisest among them were contented with permission to worship undisturbed. His aim ever was to maintain peace abroad and quiet at home, and the chief blot on his ministerial career is that through love of office he allowed himself to be drawn into the war with Spain. In business matters he was methodical; his judgment was sound in financial affairs; and his speeches were marked by clearness of expression. Pope, who loved him not, has borne witness to his merits "in the happier hours of social pleasure," but neither in private nor in public life were his manners refined or his estimates of men and women exalted. "All these men have their price" was his estimate of members of the House of Commons, and although he gathered together at Houghton many of the masterpieces of painting he was not a lover either of art or of letters. All the eminent writers of the day were opposed to his rule, and at his fall his jealous spirit had driven into opposition every politician of repute. Great as his faults were, his character was suited to the temperament of the period within which he lived, and during his tenure of office his country advanced in prosperity by leaps and bounds.

His life is written by Archdeacon Coxe in three ponderous folios, and has more recently been described in one volume by Mr. Ewald. (W. P. C.)

WALPURGIS, Walpurga, or Walburga,[1] St., was born in Sussex about the end of the 7th or the beginning of the 8th century, and was educated at Winburn, Dorset, where, after taking the veil, she remained for twenty-seven years. She then at the instance of her uncle, St. Boniface, and her brother, St. Wilibald, set out along with some other nuns to found religious houses in Germany. Her first settlement was at Bischofsheim in the diocese of Mainz, and two years later (754) she became abbess of the Benedictine nunnery at Heidenheim, within her brother Wilibald's diocese of Eichstädt in Bavaria, where also another brother, Winebald, had at the same time been made head of a monastery. On the death of Winebald in 760 she succeeded him in his charge also, retaining the superintendence of both houses until her death on February 25, 779. Her relics were translated to Eichstädt, where she was laid in a hollow rock, from which exuded a kind of bituminous oil afterwards known as Walpurgis oil, and regarded as of miraculous efficacy against disease. The cave became a place of pilgrimage, and a fine church was built over the spot. She is commemorated at various times, but principally on May 1, her day taking the place of an earlier heathen festival, which was characterized by various rites marking the commencement of summer. In art she is represented with a crozier, and bearing in her hand a flask of balsam.

WALRUS, or Morse.[2] In the article Mammalia (vol. xv. p. 450) is was shown that the existing members of the Pinniped division of the order *Carnivora* are divided into three very distinct groups, the true seals (*Phocidæ*), the sea-bears or eared seals (*Otariidæ*), and the *Trichechidæ*, containing the walrus alone, in some respects intermediate between the other two, but also possessing, especially in its greatly modified dentition, peculiar characters of its own.

---

[1] French forms of the name are Gualbourg, Falbourg, Vaubourg, and Avougourg.

[2] The former word is a modification of the Scandinavian *vallros* or *hvalros* ("whale-horse"), the latter an adaptation of the Russian name for the animal.

Trichechus is the almost universally accepted generic name by which the walrus is known to zoologists, but lately some confusion has been introduced into literature by the revival of the nearly obsolete terms *Rosmarus* by some authors and *Odobænus* by others. *T. rosmarus* is the name of the species met with in the Arctic seas; that of the North Pacific, if distinct, is *T. obesus.* The following description will apply equally to both. A full grown male walrus measures from ten to eleven feet from the nose to the end of the very short tail, and is a heavy, bulky animal, especially thick about the shoulders. The head is rounded, the eyes rather small, and there are no external ears. The muzzle is short and broad, with, on each side, a group of very stiff, bristly whiskers, which becomes stouter and shorter in old animals. The tail scarcely projects beyond the skin. The fore-limbs are free only from the elbow; the hand is broad, flat and webbed, the five fingers being of nearly equal length, the first slightly the longest. Each finger has a small flattened nail, situated on the dorsal surface at a considerable distance from the end. The hind-limbs are enclosed in the skin of the body almost to the heel. The free portion, when expanded, is fan-shaped, the two outer toes (first and fifth) being the longest, especially the latter. Cutaneous flaps project considerably beyond the bones of the toes. The nails of the first and fifth toes are minute and flattened; those of the second, third, and fourth elongated, sub-compressed, and pointed. The soles of both fore and hind feet are bare, rough, and warty. The surface of the skin generally is covered with short, adpressed hair of a light, yellowish-brown color, which, on the under parts of the body and base of the flippers, passes into dark reddish-brown or chestnut. In old animals the hair becomes more scanty, sometimes almost entirely disappearing, and the skin shows ample evidence of the rough life and pugnacious habits of the animal in the innumerable scars with which it is usually covered. It is everywhere more or less wrinkled, especially over the shoulders, where it is thrown into deep and heavy folds.

Walrus.

One of the most striking external characteristics of the walrus is the pair of tusks which descend almost directly downwards from the upper jaw, sometimes attaining a length, in old animals, of 20 inches, or even more. In the female they are as long or sometimes longer than in the male, but less massive. In the young of the first year they are not visible. These tusks correspond to the upper canine teeth of other mammals. All the other teeth, including the lower canines, are much alike—small, simple, and one-rooted, and with crowns, rounded at first, but wearing to a flat or concave surface. The complete dentition appears to be $i\,\frac{3}{3}$, $c\,\frac{1}{1}$, $pm\,\frac{4}{4}$, $m\,\frac{1}{0}=\frac{9}{8}$, total 34. Many of these teeth are, however, lost early, or remain through life in a rudimentary state concealed beneath the gum. The teeth which are usually functionally developed are $i\,\frac{1}{0}$, $c\,\frac{1}{1}$, $pm\,\frac{3}{3}=\frac{5}{4}$, total 18. The tusks are formidable weapons of defence, but their principal use seems to be scraping and digging among the sand and shingle for the molluscs and crustaceans on which the walrus feeds. They are said also to aid in climbing up the slippery rocks and ledges of ice on which so much of the animal's life is passed. Although this function of the tusks is affirmed by numerous authors, some of whom appear to have had opportunities of actual observation, it is explicity denied by Malmgren.

Walruses are more or less gregarious in their habits, being met with generally in companies or herds of various sizes. They are only found near the coast or on large masses of floating ice, and rarely far out in the open sea; and though often moving from one part of their feeding ground to another, they have no regular seasonal migrations. Their young are born between the months of April and June, usually but one at a time, never more than two. Their strong affection for their young, and their sympathy for each other in times of danger, have been particularly noticed by all who have had the opportunity of observing them in their native haunts. When one of their number is wounded the whole herd usually join in a concerted and intelligent defence. Although harmless and inoffensive when not molested, they exhibit considerable fierceness when attacked, using their great tusks with tremendous effect either on human enemies who come into too close quarters or on polar bears, the only other adversary they can meet with in their own natural territory. Their voice is a loud roaring, and can be heard at a great distance; it is described by Dr. Kane as "something between the mooing of a cow and the deepest baying of a mastiff, very round and full, with its bark or detached notes repeated rather quickly seven or nine times in succession."

The principal food of the walrus consists of bivalved molluscs, especially *Mya Truncata* and *Saxicava rugosa*, two species very abundant in the Arctic regions, which it digs up from the mud and sand in which they lie buried at the bottom of the sea by means of its tusks. It crushes and removes the shells by the aid of its grinding teeth and tongue, and swallows only the soft part of the animal. It also feeds on other molluscs, sand-worms, star-fishes, and shrimps. Portions of various kinds of algæ or sea-weeds have been found in its stomach, but whether swallowed intentionally or not is still doubtful.

The commercial products of the walrus are its oil, hide (used to manufacture harness and sole-leather and twisted into tiller ropes), and tusks. The ivory of the latter is, however, inferior in quality to that of the elephant. Its flesh forms an important article of food to the Eskimo and Tchuktchis. Of the coast tribes of the last-named people the walrus forms the chief means of support. "The flesh supplies them with food, the ivory tusks are made into implements used in the chase and for other domestic purposes, as well as affording a valuable article of barter, and the skin furnishes the material for covering their summer habitations, harness for their dog-teams, and lines for their fishing gear" (Scammon).

Geographically the walrus is confined to the northern circumpolar regions of the globe, extending apparently as far north as explorers have penetrated, but its southern range has been much restricted of late in consequence of the persecutions of man. On the Atlantic coast of America it was met with in the 16th century as low as the southern coast of Nova Scotia and in the last century was common in the Gulf of St. Lawrence and on the shores of Labrador. It still inhabits the coast round Hudson's Bay, Davis Straits, and Greenland, where, however, its numbers are daily decreasing. It is not found on the Arctic coast of America between the 97th and 158th meridians. In Europe, occasional stragglers have reached the British Isles, and it was formerly abundant on the coasts of Finmark. It is rare in Iceland, but Spitzbergen, Nova Zembla, and the western part of the north coast of Siberia are still constant places of resort, in all of which a regular war of extermination is carried on. The North Pacific, including both sides of

Behring's Strait, northern Kamchatka, Alaska, and the Pribyloff Islands are also the haunts of numerous walruses, which are isolated from those of the North Atlantic by the long stretches of coast, both of Siberia and North America, in which they do not occur. The Pacific walrus appears to be as large as, if not larger than, that of the Atlantic; its tusks are longer and more slender, and curved inwards; the whiskers are smaller, and the muzzle relatively deeper and broader. These and certain other minor differences have induced some naturalists to consider it specifically distinct under the name of *Trichechus obesus*. Its habits appear to be quite similar to those of the Atlantic form. Though formerly found in immense herds, it is rapidly becoming scarce, as the methods of destruction used by the American whalers, who have systematically entered upon its pursuit, are far more certain and deadly than those of the native Tchuktchis, to whom, as mentioned before, the walrus long afforded the principal means of subsistence.

Fossil remains of walruses and closely allied animals have been found in the United States, and in England, Belgium, and France, in deposits of Quaternary and late Tertiary age.

An exhaustive account of this animal, with references to all the authors who have written upon it, will be found in Allen's *History of North American Pinnipeds*, 1880. (W. H. F.)

WALSALL, a municipal and parliamentary borough and market-town of Staffordshire, England, is situated chiefly on an eminence above a rivulet tributary to the Tame, on various canals and branch railway lines, 8 miles north-northwest of Birmingham and 123 northwest of London. The principal street is spacious and regular, and, although the side streets are generally crooked and mean, the suburbs are for the most part built with regularity and neatness. The parish church of St. Matthew, occupying a prominent position on an eminence, is a handsome modern building in the Transition style. The other five parish churches are also all modern. The schools include the grammar school, founded in 1554 for the education of boys, natives of Walsall, in the classics, the blue coat and national infant schools, and several board schools. The public library, established in 1859, enlarged in 1872, contains about 12,000 volumes; the scientific and art institution was established in 1854, and the literary institute in 1883. Among the principal public buildings are the town-hall in the Italian style, erected in 1866; the guild hall (1773), the theatre (formed out of the old agricultural hall in 1881), the drill hall (1866), the temperance hall (1866), the county court-house (1869), and the post-office (1879). The charitable institutions include the corporation almshouses (1825); Harper's almshouses for six women, founded in the reign of James I. and rebuilt in 1793; the Henry Boy's almshouse, opened in 1887; the memorial cottages at Caldmore, erected in 1868 by private benefaction of two townspeople, for twelve poor couples or widows; the Walsall cottage hospital (1863); the epidemic hospital (1872); and a number of minor charities. In the vicinity of the town are extensive coal-mines and limestone quarries. Ironstone is also obtained, and brick clay is dug. The town possesses iron and brass foundries, corn mills, and tanneries. One of the staple industries is the manufacture of the various kinds of ironmongery required in the construction of harness and carriages. Locks and keys, bolts, pulleys, and other hardware goods are also largely manufactured. The town is governed by a mayor, six aldermen, and eighteen councillors. The area of the municipal borough was extended in 1877 to 6929 acres; the population in 1871 was 46,447 (estimate of that in the extended area 49,018), and in 1881 it was 58,795. The population of the parliamentary borough (area 7478 acres) in 1871 was 49,018, and in 1881 it was 59,402.

In the early part of the 10th century Walsall was fortified by Ethelfleda, daughter of Alfred the Great and countess of Mercia. At the time of the Conquest it was retained by William as a royal demesne for about twenty years, until it was bestowed on Robert, son of Asculpus, who had accompanied the Conqueror to England. Subsequently it was owned by Richard Neville, earl of Warwick, the king-maker, and it was held successively by Henry VII. and Henry VIII. By the latter it was granted to John Dudley, duke of Northumberland, on whose attainder and execution in the reign of Mary it was forfeited and came into the possession of the Wilbrahams, from whom it passed by marriage to the Bridgmans. It is spoken of by Camden as "none of the meanest of market towns." Queen Elizabeth visited Walsall in the 28th year of her reign, and made a grant of lands to the town. Walsall was the residence of Henrietta Maria for a short time in 1643. It is a borough by prescription, but received charters from Edward III. and Henry IV., confirming the privileges and immunities conferred on it by previous sovereigns. Its oldest charter is that bestowed in the 3d of Charles I., which was confirmed in the 13th of Charles II. It is now governed under the Municipal Act of 1835. It was constituted a parliamentary borough by the Reform Act of 1832, and returns one member to parliament.

WALSH, WILLIAM (1663–1709), is included among Johnson's *Most Eminent English Poets*, but is justly said to be "known more by his familiarity with greater men than by anything done or written by himself." It was he who gave Pope in his boyhood the advice to study correctness. The value of his counsel is acknowledged in the *Essay on Criticism* (l. 729). He was a native of Worcestershire, represented his native county in several parliaments, and was gentleman of the horse to Queen Anne.

WALSINGHAM, SIR FRANCIS (*c.* 1536–1590), secretary of state under Elizabeth, was descended from an old Norfolk family, and was the third and youngest son of William Walsingham of Scadbury, Chislehurst, Kent, where he was born about 1536. After a good private education he entered King's College, Cambridge, but did not take a degree. He remained abroad during the reign of Mary, and the knowledge of foreign languages he thus acquired is said to have commended him to the notice of Cecil, Lord Burghley. In the parliament which met in January, 1558–59, he was returned for Banbury, and in that which met in January, 1562–63, for both Banbury and Lyme Regis; he decided to sit for the latter place. Nothing further is known of his political history, till in 1568 he wrote to Cecil a letter on the Darnley murder, which shows that he enjoyed the confidence of Cecil and the regent Murray, and was fully convinced of Queen Mary's guilt. In the following year Ridolfi, the papal agent, was confined, under suspicion of conspiracy, in Walsingham's house. In August, 1570, Walsingham was selected as special ambassador to France in connection with the negotiations for the toleration of the Huguenots, and in December took up his residence as permanent ambassador at Paris. On the 19th April, 1572, he was successful in obtaining the signature of a treaty of peace between England and France, but the beneficial results of his skilful diplomacy in connection with the negotiations for the Anjou and Alençon marriages were neutralized by the uncertain and changeable moods of Elizabeth, and finally frustrated by the massacre of St. Bartholomew. He took his leave of the king of France on 23d May, 1573, and on 20th December of the same year he was made secretary of state. On 1st December, 1577, he was knighted, and on 22d April of the following year made chancellor of the order of the garter. In June following, along with Lord Cobham, he was sent to the Netherlands to assist in arranging a pacification of the States, but the extraordinary vacillation of Elizabeth rendered his mission a total failure. In July, 1581, he was again sent on an embassy to Paris, but his instructions were of a kind both so dishonorable and so foolish that he said he wished rather the queen had sent him to the Tower. In such circumstances he could only endeavor to temper and qualify the policy of Elizabeth in such a manner as to prevent a fatal breach in the relations between the two countries, and in this he was successful. His embassy to Scotland in 1583 to endeavor to persuade James to dismiss the earl of Arran was also, as he prognosticated, a failure. He therefore recommended that the purpose of Elizabeth should be effected by fostering a conspiracy among the Scottish nobles, but the project was not carried out for some time afterwards. In 1584 Walsingham was appointed *custos rotulorum* of Hants and recorder of Colchester, and in 1585 high steward of Winchester. On 23d November, 1586, he was returned member for Surrey, and again on 29th October, 1587.

From the first Walsingham, equally with Cecil, Lord Burghley, was strongly hostile to Queen Mary of Scotland. By constant watchfulness and the skilful use of spies he succeeded in discovering the inmost secrets of her policy and plans. He permitted the Babington conspiracy to develop until letters passed between Babington and Mary which, if they are to be accepted as genuine, proved that the scheme for the assassination of Elizabeth had Mary's full approval. Mary and her friends declared that Walsingham had counterfeited her ciphers; but that Babington sent her letters informing her of the assassination scheme is beyond denial. Mary's friends, without any proof but her own asseveration, affirm that the letters never reached her, and that Mary's letters in reply, the authenticity of which Babington to the last never doubted, were forged by the agents of Walsingham. The asseveration of Mary is, however, robbed of all value by the fact that, in addition to denying the authenticity of the letters, she denied all knowledge of the Babington conspiracy; for Mendoza, the Spanish ambassador, while the plot was in progress, wrote to Philip II. that Mary had informed him she was fully acquainted with it. The accusation against Walsingham, that he was an accomplice in bringing Mary to the block on false and forged evidence, cannot therefore be entertained, although there cannot be any doubt that he regarded her execution as a happy deliverance from a position of great political embarrassment. He was one of the commissioners on her trial, and on Mary hinting that the incriminating letters had been written by him, called God to witness that he "had done nothing unbecoming an honest man."

By becoming surety for the debts of Sir Philip Sidney, Walsingham, on account of a flaw in the power of attorney left by Sidney, found himself on Sidney's death unexpectedly involved in pecuniary ruin. But, although one of the ablest and wisest of Elizabeth's councillors, his honesty had frequently ruffled her self-esteem, and she witnessed his embarrassments without deigning to lend him the smallest help. He died at his house in Seething Lane, London, 6th April, 1590, in circumstances of so great poverty that his friends buried him in St. Paul's at night to save the expense of a public funeral. Walsingham was a Puritan in his religious principles, but was unable to obtain for the Puritans the consideration from Elizabeth he desired. He established in 1586 a divinity lectureship at Oxford; he was a general patron of learning; and he encouraged Sir R. Hakluyt and other navigators in their voyages of discovery. By Spencer he is described as

> "The Great Mæcenas of this age
> As well to all that civil acts professe
> As those that are inspired with martial rage."

A large number of Walsingham's letters and state documents are in the library of the British Museum and State Paper Office. An account of his embassies to France with letters and despatches is contained in the *Compleat Ambassador*, edited by Sir Dudley Digges, 1655; the "Heads of a Conference between James VI. and Sir Frances Walsingham, September, 1853," is published in vol. i. of the *Bannatyne Miscellany*; and his "Journal from December, 1570, to April, 1583," is published in vol. vi. of the *Camden Miscellany* (1871). The *Arcana Aulica or Walsingham's Prudential Maxims for the Statesman and the Courtier*, London, 1655, said to have been translated from the Spanish, was probably translated by another Walsingham than Sir Francis. In Sir Robert Cotton's *Cottoni Posthuma* is a short article entitled "Sir Francis Walsingham's Anatomizing of Honesty, Ambition, and Fortitude."

WALTHAM, a city in Middlesex county, Massachusetts, United States, like the other so-called cities and towns of New England is in effect a township, containing several bodies of urban population, together with rural districts. It is situated about 9 miles west-northwest from Boston, being in fact a suburb of that city, in a country of rounded hills of glacial gravel. Besides the large village of Waltham, there are comprised in the city five others, viz., Bleachery, Chemistry, New Church, Prospectville, and Robert's Crossing. These have absorbed nearly all the population of the city, the rural inhabitants being comparatively few in number. The population, by the State census of 1885, was 14,609, about one-fourth being of foreign birth. Waltham is known all over the world for its machine-made watches, of which over 1400 are turned out daily. It has also a cotton-mill, a bleachery, and watch-tool manufactories.

The present area of Waltham was settled in 1630 by Puritans. In 1783 the town was incorporated, and in 1884 it received a city charter.

WALTHAM ABBEY, or **WALTHAM HOLY CROSS**, a market-town of Essex, England, on the borders of Hertfordshire and Middlesex, is situated on the Lea, near the great northern road, and on the Cambridge branch of the Great Eastern Railway, 13 miles north of Liverpool Street station, London. The town lies in a hollow, with streets for the most part crooked and narrow, and although many additions have lately been made it still retains much of the characteristic appearance of an old town. Of the former magnificent abbey church the only portion of importance now remaining is the nave, forming the present parish church, the two easternmost bays of the nave being converted into the chancel. It is a very fine specimen of Norman, and in the opinion of Mr. Freeman forms part of the original building of Harold, although others assign its date to the time of Henry I. Only the western supports of the ancient tower now remain. A tower corresponding with the present size of the church was erected in 1556 and restored in 1798. On the south side of the church is a lady chapel of about the end of the reign of Edward II. or beginning of that of Edward III., containing some good decorated work. Bishop Hall became curate of Waltham in 1612, and Thomas Fuller was curate from 1648 to 1658. At Waltham Cross on the great northern road, about a mile west of Waltham, is the beautiful cross erected (1291–94) by Edward I. at one of the resting-places of the corpse of Queen Eleanor on its way to burial in Westminster Abbey. It is of Caen stone and is supposed to have been designed by Pietro Cavalini, a Roman sculptor. It is hexagonal in plan, and consists of three stages, decreasing towards the top, which is finished by a crocketed spirelet and cross. The lower stage is divided into compartments enclosing the arms of England, Castile and Leon, and Ponthieu. It underwent restoration in 1833, and a scheme for the same object was started in 1885. The old Elizabeth market-house that formerly stood in the market-square of Waltham was taken down in 1852. The town is the seat of a county court for Epping division of Essex, and possesses a court-house erected in 1849. The royal gunpowder factory is in the immediate vicinity; and the town possesses guncotton and percussion-cap factories, flourmills, malt kilns, and breweries. Watercresses are largely grown in the neighborhood, and there are extensive market-gardens and nurseries, including Paul's famous rose nursery. The area of the urban sanitary district of Waltham Holy Cross, which is identical with the parish of Waltham Abbey and is in the civil county of Essex and registration county of Middlesex, is 11,017 acres, the population being 5197 in 1871 and 5368 in 1881.

Waltham appears first in history as the hunting seat of the Danish thane Tovi or Tofi, the royal standard-bearer at whose wedding feast Hardicanute died. The great forest on the edge of which it was built was long known as the forest of Waltham, but the only portion of it now remaining is called Epping forest. A wonderful cross which had been found in Tovi's land at Montacute, Somerset, was brought to Waltham, and Tovi built a church for its reception, which was named the Church of the Holy Cross. When the estate after being confiscated to the crown came into the possession of Harold, he pulled down Tovi's church and built a new one of great magnificence, which was consecrated in 1060. He also founded a great secular college, which, though usually referred to as an abbey, did not, as is pointed out by Mr. Freeman, become a religious house till the reign of Henry II. Shortly before the fatal battle of Hastings, Harold made a pilgrimage to Waltham, bringing with him many gifts. His body, which was first buried under a cairn at Hastings, was subsequently brought to Waltham and buried in the place of honor by the high altar. The tomb was destroyed about 1540. The site and property of the abbey were given by Henry VIII. to Sir Anthony Denny, whose grandson, Sir Edward Denny, was created by James I. baron of Waltham, and by Charles I. earl of Norwich. The town obtained a grant of a market from Henry III.

See "Architecture and Early History of Waltham Abbey Church," by E. A. Freeman, and other papers in vol. ii. of *Transactions of the Essex Archæological Society*; Thomas Fuller's *History of Waltham Abbey*; Stubbs's *Foundation of Waltham Abbey*; and Freeman's *Norman Conquest*.

WALTHAMSTOW, a town of Essex, England, now practically a suburb of London, is situated a short distance east of the river Lea, on a branch of the Great Eastern Railway, 6 miles north of Liverpool Street station. The original village grouped round the church is of comparatively small dimensions, but a large number of houses and villas have been built along the high road, from which diverge a number of streets and "ends." The church of St. Mary existed at a very early period, but the present building, chiefly of brick, was erected in 1535 by Sir George Monoux, lord mayor of London, and has undergone frequent alteration and improvement. Besides other old brasses it contains in the north aisle the effigies in brass of Sir George Monoux and Anne his wife. Among the other public buildings are the town hall, erected in 1876 at a cost of £4500 [$21,870], the literary institute, founded in 1882, and the workingmen's club and institute. There are a number of educational institutions, including a school of art connected with the science and art department of South Kensington, the Monoux grammar school, the Forest school, founded in 1834 in connection with King's College, and the home for orphan boys. The benevolent and charitable institutions include the public dispensary (1873), the Leyton and Walthamstow hospital home for children (1877), Sir George Monoux's almshouses for thirteen poor men (1527), the Collard almshouses for ten married couples (1851), and the Squire almshouses for widows of decayed tradesmen. In the vicinity are the reservoirs of the East London Waterworks Company. On the banks of the Lea there are flour-mills and an oil-mill. The population of the urban sanitary district (area 4374 acres) in 1871 was 10,692, and in 1881 it was 21,715.

In Domesday the name occurs as Welamestun. In the reign of Edward the Confessor it belonged to Waltheof, son of Siward, earl of Northumberland, who married Judith, niece of the Conqueror, who betrayed him to his death in 1075. The estate subsequently passed to Guy de Beauchamp, earl of Warwick, and on the attainder of Earl Thomas in 1396 reverted to the crown. Afterwards it came into the possession of Edmund Beaufort, duke of Somerset; from the Somersets it passed to Sir George Rodney, and subsequently it came to the Maynard family. It is supposed to have been the birthplace of George Gascoigne the poet (d. 1577). Sir William Patten, commissioner of the navy, the friend of Pepys, had his seat at Walthamstow, and was frequently visited there by Pepys.

WALTHER, BERNHARD (1430–1504), astronomer, was born at Nuremberg in 1430. He was a man of large means, which he devoted to scientific pursuits. When REGIOMONTANUS (*q.v.*) settled at Nuremberg in 1471, Walther built for their common use an observatory and a printing office, from which numerous calendars and ephemerides were issued, which became of great importance for the voyages of discovery. At this, the first German observatory, clocks driven by weights were first used in astronomical observations in 1484. The observations, continued until Walther's death in May, 1504, were published by Schoner in 1544, and by Snell in 1618, as an appendix to his edition of Landgrave William's observations.

WALTHER VON DER VOGELWEIDE (*c.* 1170–*c.* 1230), the most illustrious of the German minnesänger, was born in Tyrol between 1165 and 1170. He belonged to a noble family, but had no hereditary possessions. At an early age he seems to have given evidence of an aptitude for poetry, and his genius was developed under the influence of the older poet, Reinmar, whom he soon far surpassed. His earliest patron was the young and brilliant Duke Frederick of Austria, at whose court in Vienna he spent several years. After Duke Frederick's death Walther betook himself to King Philip, at whose coronation in Mainz, on the 8th September, 1198, he was present. King Philip appreciated his genius, but nothing is definitely known as to their relations to one another, or as to the causes which brought their connection to an end. After a short stay at the court of Duke Leonhard of Carinthia Walther went to Eisenach, where poets were always welcomed by the landgrave Hermann. Here he remained until 1211, when the landgrave, in deference to the pope, joined some other princes in an attempt to secure the crown for the prince afterwards known as Frederick II. Walther, who disapproved of this policy, soon afterwards entered the service of the emperor Otho; but, the emperor having proved unfriendly towards him, he associated himself with the cause of Frederick, who greatly pleased him by granting him a small fief near Würzburg, thereby gratifying a wish the poet had often expressed. He might now have led a settled life, but he had so long been accustomed to go from court to court that it was apparently hard for him to live without the excitement of travel and adventure. In 1217 he was at the court of Duke Leopold of Austria, after whose departure for the Holy Land he appears to have been received first by the duke's uncle, Henry of Medlik, then by Berthold of Andechs, the patriarch of Aquileia. On the return of Duke Leopold Walther again spent some time with him; but in 1220 he joined the retinue of the imperial vicar Engelbert of Cologne and Frederick II.'s son, Henry, to whom he seems to have acted as tutor. In 1224 Walther retired to Würzburg, where, although living in privacy, he watched closely the course of public affairs. He may have taken part in the crusade of 1228, but he certainly did not reach Palestine. He died about 1230 at Würzburg, where, under a tree in the Laurence garden of the new minster, a stone was long pointed out as that which, according to tradition, marked his grave. A new monument to him was erected at Würzburg in 1843, and a statue of him was unveiled at Innsbruck in 1877.

Walther von der Vogelweide was a poet not only of exquisite sensibility, but of a frank, independent, and manly character. He lived in a troubled age, when church and state were often in deadly conflict. In this struggle, in which he took keen interest, his sympathy was wholly with the imperial cause, and he did much to influence opinion by the vigor with which he attacked the extravagant pretensions of the papacy. While defending the rights of secular rulers, he did not forget their duties, and many of his verses—considering the period to which they belonged—display a remarkably clear and generous conception of the principles of humanity and freedom. In writing of love, the favorite subject of the minnesänger, he had all the brightness, freshness, and gayety of the best of his contemporaries, and he excelled them in his delicate appreciation of the noblest womanly qualities. His love of nature, especially in the season of spring, was an essential element of his intellectual and emotional life, and gives an enduring charm to the poems in which it is incidentally or indirectly expressed. He was a master of all the forms of verse used in Middle High German, and the perfection of his rhythm and diction, combined with the depth and wide range of his ideas, secures for him an enduring place in the front rank of the lyrical poets of his country.

A critical edition of his poems was issued by Lachmann in 1827, and there have been later editions by Wackernagel, Rieger, and Pfeiffer. There are renderings into modern German by Simrock, Koch, and Weiske. An admirable biography of the poet was written by Uhland (1822). Biographical and critical studies have also been written by Reuss, Rieger, Menzel, and Böse.

WALTON, or WALTON-LE DALE, a township of Lancashire, is situated on the south bank of the Ribble, 1½ miles southeast of Preston. The township includes the town of Walton-le-Dale, the villages of Bumber Bridge and Higher Walton, and several hamlets. The Ribble is crossed by a stone bridge of three arches erected in 1782, connecting Walton-le-Dale with Preston. The church of St. Leonard, situated on an eminence to the east of the town, was originally erected in the 11th century. The earliest portions of the present building are the chancel and tower, in the Perpendicular style, the nave having been rebuilt in 1798, while the transepts were erected in 1816. The nave was re-pewed in 1855 and the chancel restored in 1864. There are a number of interesting old brasses and monuments. A workingmen's institute was built in 1881. Cotton-spinning is carried on, and there are market-gardens in the vicinity. The population of the urban sanitary district (area 4683 acres) was 8187 in 1871 and 9286 in 1881.

Walton occupies the site of a Roman station, probably that of *Coccium*. The manor was granted by Henry de Lacy about 1130 to Robert Banastre. It afterwards passed by marriage to the Langtons, and about 1592 to the Hoghtons, of Hoghton. Walton was the principal scene of the great battle of Preston, fought on the 17th August, 1648, between Cromwell and the duke of Hamilton. In 1701 the duke of Norfolk, the earl of Derwentwater, and other Jacobites incorporated the town by the style of the "mayor and corporation of the ancient borough of Walton." In 1715 the passage of the Ribble was bravely defended against the Jacobites by Parson Woods and his parishioners.

WALTON, or WALTON-ON-THE-HILL, a township of Lancashire, England, now practically a suburb of Liverpool, 3 miles northeast of the central station. It consists largely of villas and the better class residences, but a considerable portion of the Parish Church district is occupied by laborers and artisans. The parish church, dedicated to St. Mary, was originally founded in 1326, but has all been rebuilt within recent times, the nave in 1742, the chancel in 1810, and the embattled western tower in 1831–32. There are also situated within the township the West Derby union workhouse, erected in 1868 at a cost of £10,000 [$48,600.00]; the borough prison, 1855, £180,000 [$874,800.00] (which, however, is by a special Act of Parliament included within the borough of Liverpool); and the county police station, 1885, £8000 [$38,880.00]. One of the attractions of Walton is Stanley Park, 100 acres in extent, opened in 1870 at a cost of £200,000 [$972,000.00]. In the neighborhood are also the Liverpool parochial cemetery, the Anfield Park cemetery, and the Kirkdale cemetery. The population of the urban sanitary district (area 1907 acres) in 1871 was 6449, and in 1881 it was 18,536.

The parish of Walton originally included Liverpool, which was separated from the mother church in 1699. At Domesday it was held by a Saxon named Winestan, and subsequently it was for some centuries in the possession of a family who took from it their name. The earl of Sefton is now lord of the manor.

WALTON, BRIAN (1600–1661), bishop of Chester, and editor of the great London Polyglott Bible, was born at Seymour, in the district of Cleveland, Yorkshire, in 1600. He went to Cambridge as a sizar of Magdalene College in 1616, migrated to Peterhouse in 1618, was bachelor in 1619, and master of arts in 1623. After holding a school mastership and two curacies he was in 1626 made rector of St. Martin's Orgar in London (1626), where he took a leading part in the contest between the London clergy and the citizens about the city tithes, and compiled a treatise on the subject, which is printed in Brewster's *Collectanea*, 1752. His conduct in this matter displayed his ability, but his zeal for the exaction of ecclesiastical dues was remembered to his hurt in 1641 in the articles brought against him in Parliament, which appear to have led to the sequestration of his very considerable preferments.[1] He was also charged with Popish practices, but on frivolous grounds, and with aspersing the members of Parliament for the city. Up to this time he was perhaps more an active ecclesiastic than an eager student. In 1642 he was ordered into custody as a delinquent; thereafter he took refuge at Oxford, and ultimately returned to London to the house of Dr. Fuller, dean of Ely, whose daughter Jane was his second wife. In this retirement he planned and executed his great work, a Polyglott Bible which should be completer, cheaper, and provided with a better critical apparatus than any previous work of the kind (see POLYGLOTT). The proposals for the Polyglott appeared in 1652, and the book itself came out in six great folios in 1657, having been printing for five years. England had at this time a band of Biblical and Oriental scholars of unusual distinction, and Walton could reckon among his active helpers Usher, Lightfoot, and Pococke, Castle, Wheelock, and Patrick Young, Hyde, Thomas Greaves, and others of less note. The great undertaking was supported by liberal subscriptions, and Walton's political opinions did not deprive him of the help of the Commonwealth; the paper used was freed from duty, and the interest of Cromwell in the work was acknowledged in the original preface, part of which was afterwards cancelled to make way for more loyal expressions towards that restored monarchy under which Oriental studies in England immediately began to languish. To Walton himself, however, the Reformation brought no disappointment. He was consecrated bishop of Chester in December, 1660. In the following spring he was one of the commissioners at the Savoy Conference, but took little part in the business. In the autumn of 1661 he paid a short visit to his diocese, and returning to London he fell sick and died on 29th November.

However much Walton was indebted to his helpers, the Polyglott Bible is a great monument of industry and of capacity for directing a vast undertaking, and the *Prolegomena* (separately reprinted by Dathe, 1777, and Wrangham, 1825) show judgment as well as learning. The same qualities appear in Walton's *Considerator Considered* (1659), a reply to Dr. John Owen's *Considerations*, who thought that the accumulation of material for the revision of the received text tended to atheism. Among Walton's works must also be mentioned an *Introductio ad Lectionem Linguarum Orientalium* (1654, 2d ed. 1655), meant to prepare the way for the Polyglott.

See Henry J. Todd, *Memoirs of the Life and Writings of Walton*, London, 1821, in 2 vols., of which the second contains a reprint of Walton's answer to Owen.

WALTON, IZAAK (1593–1683), author of *The Compleat Angler*, hooked a much bigger fish than he angled for when he offered his quaint treatise to the public. There is hardly a name in our literature, even of the first rank, whose immortality is more secure, or whose personality is the subject of a more devoted cult. Not only is he the *sacer vates* of a considerable sect in the religion of recreation, but multitudes who have never put a worm on a hook—even on a fly-hook—have been caught and securely held by his picture of the delights of the gentle craft and his easy leisurely transcript of his own simple, peaceable, lovable, and amusing character.

A succession of devotees have supplemented by patient inquiry what he tells us of himself. He was born at Stafford in August, 1593; the register of his baptism gives his father's name as Jervis, and nothing more is known of his parentage. He settled in London as a shopkeeper, and at first had one of the small shops, seven and a half feet by five, in the upper story of Gresham's Royal Burse or Exchange in Cornhill. In 1624 he had a shop in Fleet Street opposite the Temple, and was described as a linen-draper. In 1632 he bought a lease of a house and shop in Chancery Lane, and was described as a "sempster" or milliner.[1] His first wife, married in December, 1626, was Rachel Floud, a great-great-niece of Archbishop Cranmer.[2] She died in 1640. He married again soon after, his second wife being also of distinguished clerical connection, Anna Ken—the pastoral "Kenna" of *The Angler's Wish*—sister of Thomas Ken, afterwards bishop of Bath and Wells. When the civil war broke out he retired from business. He had bought some land near his birthplace, Stafford, and he went to live there, but, according to Wood, spent most of his time "in the families of the eminent clergymen of England, of whom he was much beloved." His second wife died in 1662, and was buried in Worcester cathedral church, where there is a monument to her memory. One of his daughters married Dr. Hawkins, a prebendary of Winchester, in whose house he died in December, 1683, at the age of ninety. The last forty years of his long life seem to have been spent in ideal leisure and occupation, the old man travelling here and there, visiting his "eminent clergymen" and other brethren of the angle, compiling the biographies of congenial spirits, and collecting here a little and there a little for the enlargement of his famous treatise.

---

[1] He was from January, 1635–36, rector of Sandon, in Essex, where his first wife, Anne Claxton, is buried. He appears to have also been a prebendary of St. Paul's, and for a very short time he had held the rectory of St. Giles in the Fields.

The first edition of *The Compleat Angler* was published in 1653, but the peaceful angler continued to add to its completeness in his leisurely way for a quarter of a century. There was a second edition in 1656, a third in 1661 (identical with that of 1664), a fourth in 1668, and a fifth in 1676. In this last edition the thirteen chapters of the original have grown to twenty-one, and a second part was added by his loving friend and brother angler Charles Cotton, who took up "Venator" where Walton had left him and completed his instruction in fly-fishing and the making of flies. Walton did not profess to be an expert with the fly; the fly-fishing in his first edition was contributed by Mr. Thomas Barker, a retired cook and humorist, who produced a treatise of his own in 1659; but in the use of the live worm, the grasshopper and the frog "Piscator" himself could speak as a master. The famous passage about the frog—often misquoted about the worm—"use him as though you loved him, that is, harm him as little as you may possibly, that he may live the longer"—appears in the original edition. The additions made as the work grew were not merely to the didactic part; happy quotations, new turns of phrase, songs, poems and anecdotes were introduced as if the leisurely author, who wrote it as a recreation, had kept it constantly in his mind and talked it over point by point with his numerous brethren. There were originally only two interlocutors in the opening scene, "Piscator" and "Viator;" but in the second edition, as if in answer to an objection that "Piscator" had it too much in his own way in praise of angling, he introduced the falconer, "Auceps," changed "Viator" into "Venator," and made the new companions each dilate on the joys of his favorite sport.

Although *The Compleat Angler* was not Walton's first literary work, his leisurely labors as a biographer seem to have grown out of his devotion to angling. It was probably as an angler that he made the acquaintance of Sir Henry Wotton, but it is clear that Walton, whatever his education and breeding may have been, must have had more than a love of fishing and a humorous temper to recommend him to the friendship of the accomplished ambassador. At any rate, Wotton, who had intended to write the life of John Donne, left the task to Walton, who had lamented his pastor's death in an *Elegy* in 1633, and now completed and published the life, much to the satisfaction of the most learned critics, in 1640. Sir Henry Wotton dying in 1639, Walton undertook his life also; it was finished in 1642, and published in 1651. His life of Hooker, was published in 1662, George Herbert in 1670, and Bishop Sanderson in 1678. All these subjects were endeared to the biographer by a certain gentleness of disposition and cheerful piety; three of them at least, Donne, Wotton and Herbert, were anglers. Their lives were evidently written with loving pains, in the same leisurely fashion as his *Angler*, and like it are of value less as exact knowledge than as harmonious and complete pictures of character. Walton also rendered affectionate service to the memory of his friends Sir John Skeffington and John Chalkhill, editing with prefatory notices Skeffington's *Hero of Lorenzo* in 1652, and Chalkhill's[3] *Thealma and Clearchus* a few months before his own death in 1683. Two political letters, published in 1680, under the title *Love and Truth*, though conciliatory enough in temper to be Walton's, are ascribed to him on somewhat doubtful authority (see Zouch's *Lives*, vol. ii. p. 387, ed. 1817).

There are biographies of Walton himself by Sir John Hawkins (prefixed to an edition of the *Angler*, 1760), Dr. Zouch (appended to an edition of the *Lives*, 1796), and Sir Harris Nicolas (prefixed to an edition of the *Angler*, 1836). There are notices also, with additional scraps of fact, annexed to two great American editions, Bethune's (1847, particularly splendid) and Dowling's (1857). A facsimile of the original edition of the *Angler* was issued by Bagster in 1810, another by Elliot Stock in 1876. (W. M.)

WĂN-CHOW-FU, a prefectural city in the Chinese province of Chĕ-keang, and one of the ports opened by treaty to foreign trade is situated (28° 1′ N. lat. and 120° 31′ E. long.) on the south bank of the river Gow, about 20 miles from the sea. The site is said to have been chosen by Kwo P'oh (276–324 A.D.), a celebrated antiquary who recognized in the adjacent mountain peaks a correspondence with the stars in the constellation of the Great Bear, from which circumstance the town was first known as the Tow, or Great Bear city. Subsequently, however, the appearance in its vicinity of a white deer carrying a flower in its mouth was deemed to be so favorable an omen as to more than justify the change of its name to Luh, or Deer, city. Its present name, which signifies the "mild district," and which is correctly descriptive of the climate, though not of the inhabitants, was given to it during the last dynasty (1368–1644). The walls, which were built in the 10th century, are about 6 miles in circumference, 35 feet in height, and 12 feet broad at the top. The gates, seven in number, were put up in 1598. Wăn-chow is about 1563 miles by road from Peking and 600 from Hankow. The country in the neighborhood of the town is hilly and pretty, while opposite the northwest gate "Conquest Island" forms a picturesque object. The island is, however, more beautiful than healthy. The port, which was opened to foreign trade in 1876, has not justified the great expectations which were formed of its probable success as a commercial centre.

In 1886 the imports (excluding treasure) were valued at £118,710 [$576,930.60], and the exports at £25,751 [$125,149 86]; 44 vessels entered, of which one only was British, and 45 cleared. A noticeable feature in the year's return is the falling off in the quantity of opium imported,—only 25 piculs, 62 per cent. less than the average of the previous three years. The principal item of import is cotton goods, which showed an increase of 12 per cent. over the same average. Kerosene oil, matches, window-glass, sugar, dates, and old iron are among the chief goods imported; while among the exports kittysols or umbrellas, timber, oranges, and tea figure prominently.

WANDERING JEW. See JEW, WANDERING.

WANSTEAD, a village of Essex, England, now really a London suburb, is situated on a branch of the Great Eastern Railway (Snaresbrook station), 8 miles by rail northeast of Liverpool Street station. It possesses the usual characteristics of the better-class eastern suburbs of London. Wanstead Park, 184 acres in extent, was opened in 1882. A feature of Wanstead is Eagle Pond or Lake, 10½ acres in extent. At Lake House Hood wrote *Tylney Hall*. The population of the urban sanitary district (area about 1072 acres) is estimated to have been 4311 in 1871; in 1881 it was 5362.

Wanstead is supposed to have been a Roman Station. It belonged to the monks of St. Peter's, Westminster, and afterwards to the bishop of London, of whom it was held at Domesday by Ralph Fitz Brien. In the reign of Henry VIII. it came into the possession of the crown, and in 1549 it was bestowed by Edward VI. on Lord Rich, whose son sold it in 1577 to Robert, earl of Leicester. The original manor house was rebuilt by Lord Chancellor Rich, who was here visited by Queen Elizabeth in 1561, and for her entertainment Sir Philip Sidney wrote a dramatic interlude which was played before the queen at Wanstead garden, and is printed at the end of the *Arcadia*. Sir Richard Child, afterwards earl of Tylney, built the splendid mansion of Wanstead House in 1715 (demolished in 1822), in which the prince of Condé and others of the Bourbon family resided during the reign of the first Napoleon.

---

[1] There was more millinery in men's clothes in those days; hence his location near the fashionable Temple.

[2] See *Notes and Queries*, Nov. 15, 1873.

[3] The existence of Chalkhill was called in question by S. W. Singer in 1820, and the pastoral supposed to be Walton's own. There can be little doubt that the poet is the same person whose tomb is in Winchester cathedral, and that Walton was simply mistaken in describing him as "an acquaintant and friend of Edmund Spenser."

WAR.

Modern changes in the art of war.

WHATEVER definition of the word "army" (see ARMY) be adopted, the fact that it is a body of men organized for the effective employment of *arms* is the essence of it. Hence the nature of the most effective organization and employment of armies in active warfare at any given period has always turned upon the nature of the arms in use at the time. The laboratory and workshops of science in recent years have in fact produced and forced on a change in the nature of fighting, of a kind which it is safe to say never entered the mind of any one of the inventors whose skill made it necessary. And yet the change is of such a kind that, though due to the development of very material things, as, for instance, the greater rapidity of fire, the greater range of weapons, and the like, it is much more remarkable in its effect on the spirit of armies and the nature of fighting discipline than in almost any other aspect.

An army an organism not a machine.

In all periods of war, under all conditions of arms, the moral forces which affect armies have been the great determining factors of victory and defeat. From a date much earlier than the day when Cæsar, defeated at Dyrrachium, gained the empire of the world by so acting as to restore the *morale* of his army before the great contest at Pharsalia, it has been on this nice feeling of the moral pulse of armies that the skill of great commanders has chiefly depended. In that respect there is nothing new in the modern conditions of war. But the sequence by which the development of arms has changed the moral pivot of military power in our own times is so remarkable that it deserves to receive a somewhat careful historical statement at the outset of this article. Unless it is understood the lessons of modern fighting cannot be learnt; for there has not yet occurred a modern war in which the principles of modern fighting, as they are now universally understood among the most thoughtful soldiers of all nations, have been deliberately applied to action, after those principles have been realized and worked out in practice during peace time. And yet it is among the first of these principles that for success in our days careful peace practice, adapted to the actual conditions of fighting, must precede the entry on a campaign. When letters from the seat of war in 1866 brought home to Europe the effect which the breech-loader was producing in determining the contest, the first impression was that of simple consternation. It was supposed that Prussia, by the possession of that weapon alone, had made herself mistress of Europe. Gradually it came to be known that the secret of Prussian power lay, not in her breech-loader alone, but at least as much in her perfect organization. In 1870 her scarcely less startling successes tended for a time to produce an effect almost as blinding upon the eyes of those who watched them. There was a disposition to assume that whatever had been done in the war by the Prussians was, by the deliberate choice and determination of the best and most successful soldiers in Europe, shown to be the best thing that could be done under the circumstances. The exhaustive statement of facts contained in the Prussian official narrative and in the regimental histories, and the evidence of eye-witnesses innumerable, have, however, gradually made it evident that, valuable as the experiences of the 1870 campaign unquestionably are for soldiers of all nations, the Prussian successes were certainly not due to the carrying out of what are now regarded by the best Prussian officers themselves as the principles of action which ought to determine practice in future wars. But during the course of the war itself the Prussian army, prepared by the soundest peace training to adapt itself to whatever conditions it met with, was continually and progressively modifying its practice under the experience of conditions which it had been impossible fully to anticipate.

It is upon the surface of the facts that the extreme loss of life suddenly occasioned at particular points by the effectiveness of the fire of the new weapons, both of artillery and infantry, compelled the gradual abandonment of close formations of men, massed together in dense columns or even in closed lines, and the gradual adoption of what are known as "skirmishing" or open order formations. In other words, when the French fire fell upon the solid columns of the advancing Prussians, the column instinctively scattered. The officers and non-commissioned officers were often lost in very large proportion, and during the actual course of the fighting, without any preconceived idea on the subject, a method of attack was adopted which proceeded by successive swarms of dispersed men taking advantage of such shelter as the ground permitted. The noise of the rapid breech-loader, and the crash of an artillery able to fire much more frequently than in former campaigns, and, moreover, accumulated in much greater masses than had ever been the case before, made words of command inaudible at a distance. Hence it came to pass that small parties of men, once launched into an infantry fight, were virtually beyond all control on the part of superior officers. All that these could do to influence the action was to determine the direction and object of the first attack of each fraction, and then to furnish it with fresh supports at the proper moment, sending them forward in such a way as to cause their blows to be delivered in the most telling direction.

Here then was the great change which had come about, produced, as has been said, by the efficiency of the new weapons, but rendered possible by those changes in the characteristics of the men of whom armies are composed, which had arisen from altogether different circumstances, such as the high educational standard of the Prussian nation, and the introduction into the ranks of highly cultivated classes. The army, at all events in battle, was and could be no longer a mere mechanical weapon in the hands of its commander. If this latter could not infuse into it a spirit of hearty willing co-operation and intelligent subordination, chaos and chaos only must ensue. For the very essence of the old forms of fighting in battle, as they had been inherited from the time of Frederick the Great, and, though modified by Napoleon, had yet in this respect remained the same, was that battle movements were led up to and prepared for by an elaborate system of drill, so arranged that by the issue of predetermined words of command the officer leading at least a division of an army could decide precisely the formation it was to assume and the movements it was to make in battle. Now, though no doubt many of the preliminary movements could still be accomplished in accordance with the old drill, yet, for at least the very mile and a half over which the issue had actually to be fought out, drill had vanished, as far at all events as the infantry were concerned. All effective movements and co-operation depended on perfect organization, and on a training which made every officer and every man know almost instinctively what to do and what decisions to form as each emergency arose. The Germans had in the largest sense perfected their organization, not merely in its form, itself a manner of no small importance, but in its preparedness for battle action. This had been done chiefly by keeping and training together much larger units of command than had ever been organically worked together before. By "organic working" we specifically mean such work as leads each man to know by long habit what the part assigned to him is, and how to contribute his share in bringing about the result desired by his general. In the article ARMY will be found an exhaustive statement of the successive *forms* which army organization has assumed at different periods of history. With regard to these forms, representing as they do the condition of an army in a state of rest, suffice it to say that the ancient proverb about new wine and old bottles applies perfectly. It would not have been possible for the Germans to have secured a complete correspondence of working, a unity amid great diversity, without having devised a form of organization which assigned to every man an adequate share of work and of responsibility, by bringing a limited number of men at each step under the authority of one, those so placed in authority being themselves at the next stage, in limited number, also under one man's authority. But the very idea of organization implies more than this mere perfection of form. It implies also, as animating the whole body, a spirit developed by careful training, a mutual reliance on the certainty of the adherence of all to known principles of action.

Subordination of drill to organization.

The essential change, then, which appears to have come over modern war may be stated thus. Under the conditions of the past, the general in command of an army relied upon its perfection in drill and in formal manœuvres for enabling him to direct it with success against the weak points of an adversary. Now he must depend instead upon the perfection of its organization and of a training adapted to make each man ready when required to apply sound principles in every emergency, and, above all, as soon as possible voluntarily to place himself under authority again so as to secure unity of action. To summarize this statement in a single sentence, and employing the word organization in the larger sense explained above, the change consists in the substitution of organization for drill as a means of battle-action. In other words a living organism must take the place of a mechanical instrument.

It will be seen at once that the perfection aimed at, involving as it does not merely a mechanical learning, by rote and drill-sergeant, of required changes of position, is of a much higher order both for the individual man and for the whole body than was the case under the old conditions. On the other hand, it is not possible that the practical performance should so nearly approach the ideal as happened formerly. Hence, great as was the excellence of the Prussian army in 1870 as a whole, yet the more thoroughly that campaign is studied the more manifest will be the mistakes in point of details committed by subordinate actors. It is in the nature of things impossible that this should ever be otherwise under the conditions of war which are now established. When the choice of action in detail is left to so many hands the possibilities of error are multiplied indefinitely.

Application of past experience to strategy and tactics.

It is clear from what has been said that a change of the most complete character has come over the very principle by which armies are held together. It is by no means surprising, therefore, that a few soldiers should have arrived at the conclusion that, because of the importance of this change, all past experience of fighting has ceased to be of any importance to him who would understand the principles of war as they exist to-day. On the other hand, others of far higher authority have declared it to be certain that change has only affected that branch of the art of war which is called tactics, and that the other branch, or strategy, is in no way affected. We are not able to subscribe absolutely to either of these statements. But before stating our views it will be convenient to define the terms employed. By strategy we understand "the art of rightly directing the masses of troops towards the object of the campaign." Of modern tactics no better definition perhaps has ever been given than that of Sir Edward Hamley. After defining the limits of either subject thus—"the theatre of war is the province of strategy, the field of battle is the province of tactics,"[1] he describes the manœuvres of a modern battle-field as "the quick orderly change of highly trained and flexible masses of men from one kind of formation to another, or their transference from point to point of a battle-field for purposes which become suddenly feasible in the changing course of action."

It is necessary, in discussing the application of past experience to modern war, to make intelligible the distinction between these two fields of experience, because undoubtedly the changes wrought by time affect the two great parts of the art of war in very different ways and in a very different degree. But in fact there are many parts of the study of tactics which are not strictly included within its province when that is limited to the field of battle. The distinction between the two provinces having been understood as a general idea, it will be seen at once how it has happened that in the varied incidents of warfare it has become necessary to apply the terms "tactics" and "strategy" to other matters. For no army can determine for itself or know beforehand absolutely what will be a field or a day of battle. Hence it is necessary throughout almost the entire course of a campaign to take those precautions and to take into account those considerations which apply properly to the period of actual combat. Thus, though an enemy may in fact be many marches distant, it is necessary to provide against his possible attack, by having some troops always on the alert whilst others are marching with all the ease and security which the protection of these procures for them. It is necessary also in a similar manner to have protection for the repose of an army, and to detail troops for this purpose. All the questions, then, which concern the fixing of "advanced guards" and "rear guards," which protect the front and rear of an advancing army, and the "outposts," which protect an army at rest, are usually included in the study of tactics, though in many instances they may have nothing to do with a battle-field. But again, though the campaign—the large field of war which concerns the marches and movements of armies striving against one another to obtain positions of vantage for the actual combat—is the province of strategy, yet it may well happen that on the actual battle-field it is necessary to take account, not only of those circumstances which will help to secure victory in the fight, but of the effect which victory or defeat will have upon the campaign. All these considerations we necessarily regard as "strategical," even though they occupy our minds on a battle-field.

The art of war as a study.

For it must be emphatically asserted that there does not exist, never has existed, and never, except by pedants, of whom the most careful students of war are more impatient than other soldiers, has there ever been supposed to exist, an "art of war" which was something other than the methodic study of military history. Those who have most assisted in making the study sufficiently methodic to enable it to be of practical profit in their own profession to soldiers for future use, or to historical students in watching the play of mind between great commanders, have been invariably the most emphatic in denouncing all attempts to formulate a systematic series of "rules of war." Among generals, Mack, the unfortunate Austrian who surrendered at Ulm to Napoleon, and in our own time Count Palikao, who had made himself the laughing-stock of the English staff during the advance on Peking, and who was afterwards responsible for bringing about the catastrophe of Sedan, have been the great sticklers for the "rules of war." At least once Count Palikao, in China, came without his sword to look on at the success of operations which he had denounced as "contrary to every maxim of war." On the other hand, Sir Edward Hamley, who has done more than any other Englishman to make known to English officers the value of a methodical treatment of the study of campaigns, has most vigorously denounced such talk as this.

---

[1] *Operations of War*, 4th ed., pt. iii. ch. i.; pt. vi. ch

> "Nothing is more common," he writes "than to find in writings on military matters reference to the 'rules of war,' and assertions such as that some general 'violated every principle of war,' or that some other general owed his success to 'knowing when to dispense with the rules of war.' It would be difficult to say what these rules are, or in what code they are embodied; and an inquirer, who is somewhat puzzled, perhaps, to understand how the highest proficiency can be displayed in a science by defiance of its principles, had better resolve to base his own conclusions upon fact and reason alone, when he will probably discover that such criticisms have only very vague ideas for their foundation."

Jomini, a very eminent authority in his day, though not a little disposed to somewhat exact definition, and perhaps sometimes to over-pedantic statement, has with very little difference expressed the same view. Clausewitz, probably the most profound of all military students, has even more emphatically declared that the theory of the art of war is valuable, just in so far as it assists to guide a man through the vast labyrinth of military experience, and to prepare his mind to be ready to act for itself under the emergencies of actual war; but he adds, "it must renounce all pretension to accompany him on to the field of battle." Both he and Jomini agree in asserting that it must have become with him an instinct, almost absorbed into his blood, to be of any value to him. "The wise teacher," says Clausewitz, "restricts himself to the work of directing and assisting the mental development of his pupil, and does not try to keep him in leading-strings throughout his career." Thus from all countries those who have come to be accepted as authorities on the study of war, the very men who, if any, ought to be tempted to magnify their office, have cried aloud against the abuse of such study. It is not from them, but from non-military writers like Macaulay, that the notion of some formal code of the rules of war has been derived. Macaulay's expression about Peterborough winning battles by violating the rules of war cannot be characterized otherwise than as worthless rhetoric, not only unsupported, but absolutely contradicted by fact. So thoroughly reasoned and so entirely worked out on a principle were Peterborough's campaigns that they have in our own day served to guide one of the most brilliant of English soldiers in the conduct of one of his most successful wars. The campaigns by which Colonel Gordon saved China were largely assisted in their conception by his careful study of Peterborough's generalship in Spain.

On the other hand, it is not from writers on war, but from the greatest generals, that the most emphatic statements have come as to the paramount importance to a soldier of the careful study of past campaigns. The classical instance of the most authoritative dictum on this subject is surrounded by circumstances of dramatic interest. Napoleon in 1813, sitting after dinner surrounded by his marshals, between the first and the second battle of Dresden, was drawn to speak on this subject by Marmont, the one who, in Napoleon's own judgment and that of others, had himself the most complete knowledge of war as an art. Marmont, observing how difficult it was, during the continued strain of war itself, to improve in its practice, maintaining that rather in peace than in war could war be best studied, said to Napoleon that he thought that Napoleon's own first campaign in Italy was the most brilliant in its conception of any that he had ever fought; so that sixteen years of high command had hardly made his knowledge of war as an art more perfect. Napoleon at once admitted the truth of this, and in reply said, "Yes; Turenne was the only one of us all who constantly improved in the management of his campaigns as he advanced in years." This reply is especially remarkable, because Napoleon was not only the greatest captain of his own age, but he was by far the most careful student that the world has known of the great generals of all ages. It is an unanswerable assertion that only by study of the past experience of war has any great soldier ever prepared himself for commanding armies.

It must, however, be always a question how far the circumstances of our own time have so changed as to limit the period within which it is worth while to devote very careful study to the wars of the past. On the one hand, the greater number of officers in any army will never find time exhaustively to study all the great campaigns which would be of value if they had really so known them as to acquire the experience, as far as may be, of the various actors in them, and it is therefore of special importance that the most modern experiences at least should be completely known to them. On the other hand, even after all the campaigns which have taken place since breech-loaders and rifle-guns have become the determining factors of battles have been carefully studied, it can hardly be claimed for them that they present a picture approximately complete of all the possibilities of modern war. To any one who tells us that nothing applicable to the wars of the future is now to be learnt from the campaigns of Napoleon, or even from the events of the Peninsular War, we are prepared to reply by adducing, either from almost any one of Napoleon's most important campaigns or from the Peninsula, specific lessons, for the most part experiences of human nature, and illustrations of the mistakes which men are liable to make, which have in no wise been diminished in value by the changes which have come over the face of war.

As an instance in point, reference may here be made to a recently published study of the campaign of Fredericksburg during the civil war in America. It deals in a sound and useful manner with both strategy and tactics, and yet it is based entirely on conclusions drawn from a period of war prior to the introduction of the breech-loader. We are disposed to put it forward as a very powerful illustration of the kind of lessons which a careful student may draw from one condition of tactics and apply to another. What is most interesting in the work is perhaps the way in which those lessons are made to apply with exceptional force to the peculiar and special conditions involved in breech-loader fighting. It seems impossible for any one who has appreciated its excellence not to perceive that in a similar manner, with the like wise appreciation of those things which are permanent and those things which change, sound deductions may be drawn from even the tactical experiences of the Napoleonic era. Nay, the statement of the most brilliant and successful general in the British army of to-day appears to be indisputable, that a perusal of the words of even Cæsar himself will suggest to any thoughtful soldier, who knows something also of modern war, reflections that he may afterwards recall with advantage as applicable to modern campaigns.

That tactics have been first and most directly affected by the changes which have recently taken place in the conditions of modern war it is impossible

Changes in tactics and in strategy.

to doubt. The nature of tactics has been always of a kind more tending to admit of rapid change, and more frequently suggesting to a commander of originality new developments. Napoleon indeed declared that tactics should be changed every ten years. Strategy has always, on the other hand, been assumed to possess a more permanent character. All important changes in armament immediately affect tactics. No one now disputes the general character of the tactical changes which have been produced by the introduction of the breech-loader and the development of artillery. Indeed, when we come to describe the broad features of modern tactics, we shall be dealing with matters as to which, except as to a few specific points, it may be said that practically the military world of Europe is agreed; but we confess that we are not prepared to accept the assumption that tactics only have been changed, and that he who would be ready for future war on the grand scale must not also look for some change in the general character of strategy.

Sir E. Hamley, in his *Operations of War*, has graphically described how it was that armies lived in the days of Edward III.; how they depended absolutely upon the food and supplies which they found in the country through which they moved; and how, when they had exhausted that country, and were opposed by an enemy holding a strong position, which they could not venture to assail, they were obliged to fall back simply because they had no arrangements for obtaining supplies regularly from their own land. Now the great strategic movements of armies have depended always upon this question of food and of warlike supplies in the first instance. It will therefore be evident at once that the character of strategy changed from the moment when a system was devised by which along a regular chain of posts, or "line of communications," an army received its supplies of food, warlike implements and reinforcements, from either its own country or some other source which came to be known as its "base of supply." It began to be the object of generals to manœuvre in such a way as to interfere with the lines by which their opponents were receiving their supplies and to protect their own. In many respects, no doubt, even the Roman armies in the time of Hannibal acted on strategical principles that are applicable in our own time. Yet the change in the conditions under which armies began to live in the field was so great from the moment when, in order to facilitate and hasten their movements, they began to be thus supplied from a particular "base," and along these "lines of communication," that the art of handling them in campaigns changed almost as completely as tactics ever changed. New combinations became possible. Skill was turned into a new direction. In other words, strategy, like tactics, changes when its implements or weapons change. If now it be asked whether since the days of Napoleon and Wellington the implements of strategy have not changed almost as completely as those of tactics, it must be answered that the change has been even more complete.

Changes in the general conditions of war.

Since 1815 the face of Europe has been more altered than it had been in five previous centuries. It is now covered with a network of railways and telegraphs. The commerce of the world and its means of intercommunication have developed in a manner that has everywhere revolutionized the conditions of life. The advance of science has operated in a thousand forms upon the circumstances under which armies exist in the field. The conditions of sea transport and of sea warfare are even more completely changed than those of land. Further, it must be remembered that battle-action is itself one of the determining factors of strategy. If, in their general character, the nature of battles and the circumstances under which battles have to be fought change very materially, that in itself involves a further change in the combinations which are open for manœuvres in the field of which the ultimate object is to lead up to battle. Once more, the size of the armies which will enter into the next great campaign in Europe will be so vastly different from those which fought out the great wars of the past that their manœuvring in campaigns must necessarily be very different from anything that Napoleon undertook. Now, even during the later wars of Napoleon, Jomini was obliged to admit that many of the experiences of the past must be materially modified as armies increased in size. One of the most familiar forms in which Napoleon exercised his strategic skill lay in defeating with his own entire army a fraction of the forces opposed to him, before it could be reinforced by the remainder of the enemy. Thus the element of time essentially entered into the question. Even during the great campaign of 1813, when Napoleon, holding a central position on the Elbe, endeavored to strike from thence against the masses of the allies formed in a great circle round him at Berlin, in Silesia, and in Bohemia, experience showed that it was by no means easy to crush with sufficient rapidity armies of 120,000 men so as to prevent them from being supported in time by others. As the allies gradually closed in on him, and the distances between their different forces diminished, this became continually more and more apparent. In fact, it became clear, if it had been doubtful beforehand, that the question was altogether a matter of proportion between time, distance, and the resisting power of the several armies concerned. On the other hand, in 1814, when the nature of the country invaded caused a reduction in the size of the armies moving forward separately, Napoleon was able as of old to strike his blows right and left with telling effect.

Now, if it were possible for an army of our day, supplied with all the implements with which modern science has provided it, to meet any army of equal members, equipped as Napoleon's armies were equipped, the difference in power of the modern army would be such that it would almost be able to deal with its enemy as civilized armies provided with firearms were at first able to deal with savages possessed only of bows and arrows. The artillery of the days of Napoleon would not be able to act at all, for our modern infantry can fire with effect at a distance greater than could Napoleon's big guns. Our artillery would be able to destroy Napoleon's army before either his artillery or infantry could act against us. Thus an army of 50,000 men of our own time must be reckoned as possessing at least the resisting power of 100,000 of the days of Napoleon. It is obvious, therefore, that the relationship between time, distance, and the resisting power of armies has been greatly affected by the change in the character of weapons, and that calculations as to what a superior army can do in a given time to break up the force of an army opposing it, and to be free to deal with another army, are greatly modified.

There is another element which has largely to be taken into account in our modern battles. The expenditure of ammunition is, from the rapidity of fire, enormous. Even in the days of Napoleon, it was extremely difficult, as his own words after the battle of Ligny show, for a victorious army rapidly to turn upon a second force which had not been engaged, because of the time required for filling up the empty ammunition wagons and the men's cartouches. These difficulties under our conditions of warfare are therefore immeasurably increased.

Again, in order that an army may nowadays be isolated in the way in which Napoleon in 1805 cut off the army of Mack in Ulm and utterly destroyed it, many conditions have to be secured which were not needed then. The telegraph is a formidable enemy to such an operation. The newspapers are a still greater. When MacMahon in 1870 attempted his disastrous march to the relief of Bazaine in Metz, to the success of which secrecy was essential, his movements first became known to the Prussian headquarters through French and English journals. Thus the rapid intercommunication between town and town, capital and capital, which is now extended in all directions over Europe to an extent that makes it extremely difficult to completely prevent news of all kinds from leaking out, is an element that cannot be neglected in any strategical calculations. The change in this respect is strikingly shown by the fact that seven weeks elapsed before the news of Trafalgar reached Naples. Furthermore, distant parts of an army may, under certain conditions, be in point of time much more closely connected than they formerly were because of the facilities afforded by railways and telegraphs. There are a variety of other elements less important individually than as all contributing to the same result, which must not be ignored,—the facilities afforded for the supply of armies by compressed food and compressed forage, the enormously extended area which caters for the feeding of the European populations and the organization of the commerce of the world rendering all which that area yields rapidly available, and, lastly, the continually improving methods of machine transport by road, bicycles, tricycles, etc., making it possible to effect rapid movements without forage at all.

Furthermore, not only have we to deal with new material conditions, but, as already observed, the armies which have to be led under these new circumstances have themselves been profoundly changed, not only in their armament but in the very spirit, discipline, and organization by which they are held together. What is true of the private, of the sergeant, of the captain, in his relations with superiors, is even truer of the leader of the brigade, of the division, of the army-corps, of the co-operating army. The whole method of the Prussian discipline and organization, as it showed itself in 1870, implied an intelligent independence of action in all ranks that most seriously affected the strategical operations. In fact, in that campaign two very noteworthy points may be observed. From the first battle at Weissenburg up to and including Gravelotte, the peculiar feature of the war was that the German successes at each action—Weissenburg, Wörth, Spicheren, Colombey-Nouilly, Mars-la-Tour—were much more important in their strategical than in their tactical aspect,—much more important, that is to say, in their general influence on the campaign than in the severity of the losses in men and material inflicted on the enemy. The losses in battle were in fact greater on the side of the victors than on that of the vanquished. Yet, secondly, each of these actions, up to but not including Gravelotte, was brought on by the determination of subordinate leaders, and was not designed beforehand either by the king's headquarters or by the headquarters of any one of the three armies. It cannot of course be denied that there was an element of danger in this way of managing a campaign. But the general who attempts to carry out a modern campaign without having realized the nature of this strictly strategical experience is reckoning without his host. Armies now occupy, even when in numbers similar to those of the past, distances vastly greater than was the case in former times. One of two things must happen: either a general must attempt to prescribe the action of his subordinate leaders with a rigidity which nowadays will continually prevent them from carrying out what would be his wishes could he be on the spot to advise them; or he will find that he has, as best he may, to make his strategical movements fit into events which have not been previously designed by himself. The Prussian headquarters, realizing fully the dangers involved in the plan which they, in fact yielding to necessity, accepted, found no fault with the generals who had initiated battles which had proved successful, fearing to do more injury to the spirit of the army than would be compensated by any other advantage. Nevertheless the notes of warning thrown out in the official history of the war are clear and unmistakable. To us it appears that this condition of things is an element in modern war to be foreseen and prepared for, that it represents, not an accident of the 1870 campaign, but an almost inevitable consequence of the present condition of armies. It was their high spirit, their high training, their knowledge of war, which made the German leaders so hard to keep within the leash when they saw the prey before them, and realized that it was a matter of moments whether it could be seized or not. There is nothing like this campaign, in the peculiar mode in which its strategical aspects developed, in all the past history of war.

Changes since time of Napoleon.

It would appear, therefore, that it tends to mislead a man who is anxious to consider what combinations are open to a general in the field in our day, to assure him that strategy has undergone no change since the days of Napoleon. No doubt a soldier who had never considered how or why Napoleon triumphed over his opponents, and when and why he failed, would have very little chance of solving aright the problems of a modern campaign. The handling of armies is, before all things, in the infinite variety of its elements, a dealing with human nature, under certain peculiar conditions, a play of mind against mind, and only by a study of the masters of the game can some of its experiences be gathered. If the changed conditions under which a modern war now takes place have been realized, then all study of the martial experiences of the past will in its own degree have value. We doubt extremely if any man can fairly appreciate the character of the campaign of 1866, or the campaign of 1870, who knows nothing of the campaigns of Napoleon. To take, for instance, the earlier of the two, the Prussian strategy in it has been the subject of much dispute; and those who think that questions of war can be settled by quoting maxims of Napoleon, or of other great generals, find no difficulty in picking out sayings of his that would condemn without excuse the scheme of the Prussian campaign. Certainly we should ourselves be sorry to suggest that it is the one satisfactory model for future guidance under analogous circumstances. To us it seems that its value, as a sample of what may be done in war, depends on a careful comparison of the handling of the Prussian armies, under the conditions in which they had to act, with the mode in which Napoleon and other great generals acted under their own conditions. The point in which the Prussians offended against the received maxims of Napoleon lay in their attempting to pass the Bohemian mountains in two separate armies,—one from Silesia, one from Saxony and Prussia. The Prussian headquarters remained at Berlin in telegraphic connection with both armies up to the moment when the junction of the two had been so far effected that they were able to communicate with each other. Now Napoleon in many letters, more especially those addressed to his brother Joseph in Spain, has condemned the attempt to arrange complicated schemes for the co-operation of armies acting from different bases of supply. His reason is that such complicated schemes are rarely worked out as they are intended to be. For our own part we do not believe that the warning from the past experience on which Napoleon's views were based has ceased to be of practical importance. We think that it ought to be present to the minds of all who are working out the plan of a campaign, and that the simpler, the less complicated, the less dependent on the successful combination of a number of different elements the plan is the more likely is it to be successful. But we think also that the actual circumstances of each case as a whole must be taken into account, and that in the instance of the campaign under consideration the Prussian headquarters were fully justified in the method they adopted. Such an operation indeed would not have been safe or wise in the days of Napoleon (see below); but for the moment our contention is that the

Merit not necessarily to be estimated by success.

modifications of the art of war which are necessitated by modern conditions extend to all its branches, and that criticism of modern campaigns which is based upon maxims derived from the past, without taking account of those new circumstances, is unsound and untrue. Few things are more unsafe in war than to judge by isolated cases of success alone, as to the soundness of the principles and the capacity of the leaders concerned in bringing about the successful result. The importance of military success is, in Britain more especially, apt to be measured much more by the national interest and national excitement which the result occasions than by any careful estimate of the difficulties actually overcome and the capacity for future command exhibited by the triumphant leader. To take illustrations sufficiently distant from our own days: scarcely any victory, naval or military, has ever excited wilder enthusiasm in England than the capture of Porto Bello by Vernon in 1725;[1] scarcely any disaster, the most disgraceful that ever occurred, caused greater horror and alarm in England than the return of Moore's expedition from Corunna in January, 1809. Yet, as subsequent events showed, Vernon was by no means a very able admiral; and, on the other hand, as all who have really studied the Corunna campaign well know, few have been ever conducted with more conspicuous ability or would have justified a higher confidence in the general. It is thus of the greatest importance that statesmen at least should not be carried away by the sort of hasty criticism which deals in glib phrases, and avoids reasoned examination of facts. The maxims of Napoleon may be as easily kiln-dried and deprived of life as those of Frederick had been by the Prussian army of Jena, which was so sure of defeating the upstart aspirant to military supremacy.

To sum up, then, what has been said on the art of war. There is no royal road to the knowledge of the art of handling armies any more than to that of any other branch of human activity. All that the best summary on that subject can profess to do for a reader is to assist him in undertaking a methodic study for himself of the principles which have guided great commanders, of the experiences of those who have fought in great battles and great campaigns, in endeavoring to put himself in their place so as to see with their eyes, hear with their ears, and realize the passions which influenced them, and the circumstances under which their decisions had to be formed.

Conditions of historical study.

It is not to be forgotten that even a commonplace critic may find it easy, when all the facts are fairly laid before him, to judge what ought to have been done in a given emergency. "La critique est facile, l'art est difficile," was the motto which Muffling, the very able representative of the Prussian army at Wellington's headquarters in 1815, chose for the title-page of his studies of war. The historical student has at least one advantage which is always and absolutely denied to the general. He may never, for many reasons, have an altogether correct and a completely true picture of all the circumstances which occurred on a given day, but he has a far more complete one than could possibly be before the general at the moment when he formed his decisions. Still more, he has far better materials for judgment than any of the minor actors who had themselves to decide what they ought to do, within the limitations of the orders they received, on most incomplete knowledge of what others were doing at distant parts of the field, of the positions and designs of the enemy, and of many other facts which may now be known with certainty by any one who will read what happened. He who would prepare himself in any measure for criticising aright must put himself in the place of the soldier who has to choose,—must realize the conditions of personal danger, of noise, of passion, of incomplete and constantly misleading information, of disorder, confusion, panic, excitement, under which decisions are to be formed that must be calm and cool though they involve the lives of thousands of men, the fate of nations, and the course of history, and yet must be given then and there, for the lost moment will not return. Then he will perhaps perceive that after all the question whether he would himself have given the right decision, no matter what his previous training may have been, will be more a question of character than of knowledge. Nevertheless he is much more likely to decide aright if he has in his mind some large knowledge of the accumulated experience of the past than if, without anything to guide him, he judges by a so-called "common sense" which has already led him to ignore the earnest advice of those who have been themselves most successful in war. He is still more likely to decide aright, if, after he has acquired some general knowledge of the experience of the past, his judgment has been exercised by considering under assigned conditions what course he would actually choose to adopt. This is the method of peace preparation for war in which the Prussian officers of our day have been most carefully trained. In all their current works on the study of war they insist on the importance of this formation of the judgment and this training of choice as a matter of the utmost importance. All their most important military educational works take the form of "studies" or problems. The use of the war game and the training given by peace-manœuvres, as well as all regimental instruction, are adapted to the same end.[2]

STRATEGY.

The character of all military operations, whether those of strategy or tactics, is mainly determined by the nature of the armies engaged in them. An army as it exists in the field owes its constitution largely to those military institutions which have been fully described for each of the armies of our time under ARMY. But an army in the field differs considerably in each case from that which has been described as "the machine in a state of rest." This will be obvious at once if we consider the first question which attracts the attention of a commander about to lead an army in war. He has to choose the line of operations along which his army will act. The considerations which determine his choice are mainly connected with the necessity he is under of providing at all times for the supply of his army with food, forage, and ammunition, whilst he directs it against the point at which he is to strike.

Supplies.

In order that, for actual fighting purposes and during war, "that vast and complicated machine," an army, may so act "that the whole aggregate force of its numerous parts may be exerted in any direction and on any point required," the necessities of the individual soldier must be so provided for as not to hamper its working. A body of even thirty thousand men occupies a very considerable space and requires an amount of food that completely disturbs the ordinary peace arrangements of most places at which it arrives in the course of its movements. Hence, apart from the large means of transport, such as a great fleet or ample railway communication, which may be sometimes used to carry a whole army to a given destination, an army requires what is known as "transport" for an alto-

---

[1] [This capture was 22d Nov., 1739. See vol. xix. p. 546.—AM. ED.]

[2] We are indebted to the Volunteer Tactical Society of Manchester for by far the best essay we have seen in any language on the history and use of the war game[a]—that by Captain Spenser Wilkinson—and for the beginning of a series of translations of exercises in strategy and tactics by some of the ablest German soldiers of the day.

[a] [Kriegsspiel, the Prussian war game, invented as a recreation by Vinturinus in 1795, reappeared as a serious study in 1824, at the hands of Lieutenant Reitzwitz. A like game, "Strategos," is of American origin.—AM. ED.]

Transport.

gether different purpose. The food and ammunition must be distributed to the several battalions of soldiers composing the army from the points at which it has been collected, and within the battalions it will often be necessary to distribute it by transport to the men. Similarly for the conveyance of the sick and wounded of an army transport is required. In former days the arrangements which were made to provide an army with what was needed in this way were clumsy in the extreme. It will be remembered that during the Peninsular War the Duke of Wellington was necessarily so much occupied with this question of food and supply that he used humorously to say that he did not know that he was much of a general, but he prided himself upon being a first-rate commissariat officer. As long as all armies depended upon the services of country carts and undisciplined drivers it was always possible to carry on war by these means. An army which, like the British in the Peninsula, fought continuously in the same country for six years, gained an enormous advantage by the gradual training and discipline of its transport drivers and commissariat employés. But now that the great nations of the continent of Europe have adopted a system by which all the population is available for military service, the result is that from the moment of declaration of war a modern army enters upon a campaign with the whole of its "transport," using the term in the sense we have employed, as definitely a part of the disciplined army as its infantry, its cavalry, or artillery are. It is scarcely possible to exaggerate the importance of this change in facilitating the operations of an army in the field. The British army stands at a very great disadvantage in this respect, from the fact that the population outside the fighting ranks is not, like that of Germany or France, ready to take up its place in the departments which cater for supply and transport. This modern perfecting of the efficiency of the interior transport of an army is a new strategical weapon in the hands of a general, to be reckoned among those spoken of in the earlier part of this article. Whether with the British army in an imperfect degree, or in a Continental army more completely, this transport must be understood to be as much a part of a modern army as any of its "arms." When, during a campaign, an infantry battalion is moved by train, it, unless for a very especial emergency, requires to have with it the wagons and carts which form what is called its "regimental transport." Other transport is required to carry the more general stores needed for a brigade, a division, or an army-corps. Thus each unit of an army, if it is to remain in a condition of fighting efficiency, requires to have with it a great number of horses and carts. It is impossible to realize the nature of the problems involved in the movements of armies unless this condition is kept in mind. For instance, when the British were moving to Ismailia in 1882, it was no uncommon assumption of the critics who at home watched the operations as they went on that within a day or two at the outside the small force, not exceeding about 10.000 men, which at first moved thither from Alexandria, had effected its landing. Had it been a body of 10,000 travellers landing from a variety of ships, to be provided for by the civil arrangements of the country after they had landed, that might not have been an exaggerated estimate of what was possible. But in fact the great ships were carrying not only 10,000 travellers,[1] but great quantities of stores of all kinds, of ammunition, of railway rolling-stock, of engineer equipment, of wagons and of horses. The landing of these and their passage up a narrow causeway was necessarily a very elaborate and slow operation. The whole scheme of the campaign had to take account of the time which such work would take, and, in fact, as a consequence of it, more than half the force to be ultimately employed was left either at Alexandria or at sea, and only arrived at Ismailia many days afterwards, when the landing of the first part had advanced considerably.

The same difficulty in rapidly transferring an army, chiefly because of its attendant departments, affects all strategical movements by railway. The embarking of troops on a railway, and their disembarking from the carriages, is an operation of such slowness that for comparatively short journeys it is actually quicker for troops to march than to move by railway. The miscalculations and mistakes which were made so recently as 1870 by the French army, from failure to understand these facts, led often to the most disastrous consequences. In one instance Gambetta, insisting on sending troops by railway which Aurelle de Palladines had wished to march, hampered the operations of that veteran by the delay which was thus imposed upon certain portions of the army. There is, in fact, between the distance to be moved over and the number of troops to be moved by a line of railway a proportion which determines whether it is a more rapid operation to march or to travel by railway. In a pamphlet published shortly after the war the French emperor attributed his disasters to the general ignorance of his army as to the conditions involved in railway transport.

Continuity of supplies.

An army in the field, however, in addition to having transport present with it for distribution, needs to be able to replenish its supplies; and, though in fertile countries like France the feeding of the army may be greatly assisted by requisitions or by opening markets, it is impossible to depend for existence on these alone. Fresh supplies of ammunition at least must be continually received from a secure source, and the means must be available for feeding the army in case the resources of the country fail. Nowadays, and in most countries, the main line of supply is carried along lines of railway; but, as these are always liable to be destroyed by a retreating enemy, transport, independent of that which is required merely for distribution, must be provided in the form of wagons, carts, or pack animals sufficient to supply, for a least some days, the entire army.

Line of communications.

The source from which an army is supplied is usually spoken of as its "base" or its "base of supply." The direction in which, looking forward, a general proposes to advance, and along which it will be necessary to arrange for supply, is spoken of as his "line of operations." The direction along which the army, having already advanced to some distance from its base, is supplied, is spoken of as its "line of communications." Now, as the line of communications may come to be of great length as an army advances, and as the army needs to have its fighting strength available in the front when it is engaged with the enemy, it is clear that the long lines of road or railway along which the food and ammunition are moving forward, while parties of sick and wounded men are going backward, become weak points in its condition, which must be jealously guarded, but are difficult adequately to protect throughout their length, without detracting too much from the force in the front. In modern war the effort of the general is directed to maintaining in its full efficiency "the vast and complicated machine" which he handles, and to breaking up and destroying the efficiency of that to which he is opposed. This is the central fact to be kept in mind. Generals and soldiers, long accustomed to look at war from this point of view, frequently embody their whole conception of strategy in a phrase which to a reader, taking it in its simple form, is apt to seem like a mere truism—that the great principle of strategy is to concentrate the largest possible force at the right moment at the decisive point. So stated, strategy may seem to have nothing exceptional in its nature, and to involve no study of the nature of the great organizations of men with which it is concerned.

---

[1] The entire army employed in Egypt was about 30,000 strong. Only the force which first landed at Ismailia is here spoken of.

But, in fact, this study and this knowledge are presupposed by those who thus explain their art. It is because armies are not mere gatherings of armed men, but have a vitality of their own, that some very heavy blows may be struck against them without affecting a vital point, whilst a more skilfully directed stroke may destroy their whole future power of action. An army then, as it stands in the field, is of this character, that, while the fighting force directly opposed to the enemy is an organism which depends for its vitality upon the trained spirit of order, discipline, and enthusiasm or devotion which holds it together, and on the trained capacity for mutual and effective fighting co-operation which makes it act like one man, it has also, reaching far behind it, a long and weak tail, on the safety of which its very existence depends.

Now, if by employing a large portion, or the whole of his own force, against a smaller portion of the enemy's, a general can break up and defeat it, the advantage gained depends on the fact that he has broken up the organic unity of this portion. Even, if, as may easily happen, he has lost more men than the enemy during the effort, that very little affects the importance of the result on the future of the campaign. The strength of armies cannot be measured by counting heads within the theatre of war. It depends upon the organized force that the general is able to use and to direct. During the earlier battles of the 1870 campaign, for instance, the Germans lost very many more men than the French, but at Weissenburg they broke up the organic efficiency of a French division of about 8000 men. At Wörth they broke up the organic efficiency of 40,000 men at least. After Wörth the French army which had fought there had for the time being ceased to be an effective fighting body at all. Throughout the campaign it never recovered efficiency. The German forces, on the other hand, though they had lost more fighting men than the French, had actually increased their own effective power. Their organic unity was retained, and the spirit which inspired it had been incalculably raised by victory. But if a general can in any way interefere with the source from which an enemy is obtaining his supplies of food, ammunition, and fresh men, he can diminish his fighting power as effectually as if he broke up the organic unity in battle. A body of men who are starving can as little be held in the bonds of organization as a body of men who are dispersed. Hence the slightest movement which threatens that long and weak tail already described obliges the general whose line of communications is threatened to take steps for its protection.

At first sight it is not very obvious, since each army possesses lightly movable troops—cavalry, mounted infantry, and the like—why these should not be able to pass around the front of the opposing army, and get at the unguarded parts of the roads and railways along which the supplies are moving. To some extent, during the American civil war, this was actually done by the great leaders of horsemen on either side,—Sheridan and Longstreet.[1] In all probability a similar attempt will be made in future wars by the great bodies of Russian Cossacks, and perhaps by the cavalry of Germany, France, and Austria. But what facilitated the raids of the American cavalry of either army was the fact that they were moving in a country where all the people spoke the same language as themselves, and where they were sure to find sympathizers to supply them with needed information. Under ordinary circumstances the difficulty is that each army faces the other without any approach to complete knowledge of the distribution of the troops opposed to it. The part of the enemy's line of communication which is nearest to you is also the part nearest to the main body of that enemy's own army. In order to get at some parts of his communications which would be out of reach of support from the main army, it would be necessary to send the assailing light troops to points several marches in rear. This involves a long détour. an elaborately prepared march, and the risk that the enemy may become aware of what is designed. In fact, to use the forcible illustration which Clausewitz has employed to explain the situation in which the leader of such a raid finds himself, he is like a man entering a dark room full of assailants, never knowing when or whence a blow may be struck against him.

The situation is altogether changed if, instead of the two armies fronting one another directly, one of the two is able to make its movements in such a way that, while it surely covers its own line of communications, its direct march forward threatens to strike the line of communications of the enemy. Then the light troops can at once strike the most exposed parts in all security. Under those circumstances the army whose communications are threatened is obliged immediately, for fear of losing its means of existence, to turn to face its opponents. The advantage so gained by the army which has obliged its enemy to conform to its movements is very great. For the choice of position can no longer be made by the assailed army solely with the view to gaining success in battle. It may be obliged to fight in a position tactically disadvantageous, and if it is defeated the defeat is almost certain to be fatal: for it will be driven away from the means of replenishing supplies. On the other hand, the army to which it is opposed, if obliged by ill-success in action to retreat, falls securely back upon fresh supplies, and suffers only in proportion to the extent of its actual defeat on the battle-field.

Aims of strategy.

Thus the aims of strategy directed against the actual condition of the armies of our time are twofold,—first, to break up the organic force of the opposing army by dealing in concentrated force with fractions of the enemy, and secondly, to threaten, and if possible to destroy, the enemy's connection with the sources from which he draws his supplies. Failing either of these opportunities, a superior army may nevertheless endeavor to force on a decisive action in order to make its superiority tell. In other words, in that case the aim of strategy becomes that of securing a decided tactical advantage. It might be supposed, since these facts are known to all men who are at all likely to be placed in the command of armies in the field, that opportunities would rarely occur for delivering blows of the kind described. In fact, the difficulties in the arrangements for the movement of armies are so great, and the difficulties in obtaining information of what is going on in a theatre of war are so serious, that such chances are presented in almost every campaign. Thus in the 1870 campaign the Germans, after first breaking up comparatively small fractions of the French army at Weissenburg, Wörth, and Spicheren, succeeded in separating one great mass of the French army under Bazaine from the other under MacMahon, and in separately crushing them. In the 1877–78 campaign the Russian army in Asia Minor advanced westward past Kars against Erzeroum, driving Mouktar Pasha back before it; but the arrival of a fresh hostile force from the neighborhood of Van in the south, which, marching northwards upon Bayazid, struck directly upon the line of communications of the Russian army, produced an immediate collapse of the whole movement. The Russian army was obliged to fall back at once. Similarly, in Europe the Russian forces advancing from Tirnova had pushed their advance across the Balkans towards Adrianople, when the arrival of Osman Pasha's army, moving from Widdin upon Plevna at right angles to their line of communications, caused the whole movement to collapse, and obliged the Russians to turn their attention to the force which thus threatened them.

This movement of Osman Pasha's illustrates very

Relations of strategy and tactics illustrated.

happily several points in the relation between strategy and tactics. In the first place, Osman's move was obviously in its general character, in what we call its strategical aspect, an offensive one directed against the most vital point of the Russian field of campaign, the bridge by which they had passed the Danube at Sistova. The threatening character of the position he took up obliged the Russians in some way to dispose of his force. Very unwisely they engaged in a series of ill-prepared and ill-directed attacks upon him. The result was so completely to shatter their forces that, had Osman advanced, after his final success, against Sistova, the small Russian remnant between him and the Danube must have been driven into the river, and in all probability all the Russian forces which had crossed it would have been destroyed. But, as he remained obstinately within his field fortress at Plevna, the Russians in their turn gradually succeeded in cutting off his communications, and in obliging him to surrender that which they could not take. Thus it is clear how a site for an army may be so chosen as, from its strategical character, to induce if not to compel an enemy to attack it. It is also clear that an army fighting in a well-chosen and well-fortified position, acting on the defensive, may inflict serious defeat upon forces superior to it in numbers. Finally, it is clear that such an army will, in the long run, lose all the advantages of its success, if it is not able to advance and to act offensively when the opportunity is presented to it. It has been convenient to illustrate these points from the most recent campaign in Europe, but they had been already deduced and were fully understood long before that campaign had been entered on. They illustrate the way in which the experience of the past indicates what will happen in future war. The arrival of Osman Pasha at Plevna was a complete surprise to the Russians. Its disastrous effect for them was largely due to this cause. Apparently the same thing is true of the arrival of the Van forces at Bayazid. Yet, at the time, the existence of the Turkish forces both at Van and Plevna was known in London. The want of information at the Russian headquarters appears therefore to suggest the most extraordinary negligence on the part of the Russian staff. In any case, the vital effect upon a campaign of being able to procure the best information in any way obtainable can hardly be exaggerated. Cavalry being the arm employed to spread round an army in all directions, to gain information and to conceal the movements of the army, is on this account often justly called the strategical arm.

Secrecy of operations essential.

In whatever way strategy is employed surprise and concealment are essential to its success. On this account it will continually happen, in selecting a line of operations or a scheme of campaign, that the most important point of all is to carry out just what an enemy does not expect. Very often successful campaigns, the method of which has been subsequently much criticised, have owed their success to the fact that, from a nice calculation of time and distance, the successful general has seen that he could carry through an operation dangerous in itself, but sure not to be the one expected by his opponent. For the same reason, in all the most brilliant and successful efforts of strategic skill, steps have been taken beforehand to carry out the preliminary movements of an army in such a way as to leave an enemy up to the last moment uncertain in what direction the blow would be struck. Usually also some special effort has been made to induce the enemy to believe that he would be attacked in some very different direction from that intended.

One of the means by which this has been most successfully accomplished is the selection of the point of concentration prior to the opening of a campaign. The motives and causes for this "concentration" require, however, some explanation. It is much more easy to feed and supply an army which is distributed over a considerable area than one which is closely concentrated for the purposes of action. Furthermore, armies when moving along roads occupy a very great length. The head of the column is more or less distant from the rear in proportion to the number of troops, wagons, and animals that march by the same road. Hence it follows that the more roads an army can employ in its march the more easy will it be for its several parts to reach a required point at the same moment. Therefore, for facility of supply and for facility of movement, as long as an army is out of reach of an enemy, a considerable dispersion is advisable. But it is vitally necessary to an army entering on a campaign to be able to get all its parts together before there is any possibility of an enemy's attacking it. Otherwise it would be in the position of exposing some of its fragments to the danger of being separately attacked by superior forces of the enemy, and having their efficiency destroyed before they could be supported. Hence a concentration out of reach of an enemy's concentrated army is the preliminary necessity of every campaign.

Detention of a large force by a small one.

Though it is nearly always to the advantage of a body of troops which comes in contact with a hostile force inferior to it in fighting power to fight with it and destroy its organic unity, yet a small force may for a time succeed in delaying the movements of one very superior to it. The fighting power of an army depends upon the number of weapons that it is able to bring to bear upon its enemy. Now, as for rapid movement that does not fatigue the men an army is ordinarily obliged to march along roads, it follows that the number of weapons available for fighting in front of the line of march is very small. Hence, though a general may have under his command a very large body of troops, representing a very great amount of power when that power is developed, yet as long as he is simply marching forward he cannot immediately use that power at the point which the head of his column has reached. In order to do so he must bring those men who are far away from the front up to a position in which they can use their arms. Such an operation often takes a very long time. The time becomes much longer if, instead of marching on a road through open country or between hedge-rows, he has great mountain precipices on either side of him, so that he cannot easily get his men out of the path in which they are. Or again, if he finds that it is necessary for him to develop the power of his army in order to force his way across a bridge over a river, it may be necessary for him in the first instance to extend his artillery and infantry along the side of the stream nearest him in order to use his weapons; and then, when he wants to resume his march, he may have to bring them back again to the bridge. These are instances of the delay which is imposed upon armies which have to force their way through "defiles."

Now, if a small force is employed in delaying a larger one, which it does not intend seriously to engage, its object almost always is to induce the larger one thus to "deploy" its force from the march to a position for fighting, purposing itself to escape before the enemy seriously attacks it. It may seem at first that, as the small force has itself necessarily to pass from the march formation to the fighting position and to return again to the march, there is no gain of time. But, in fact, if the successive positions be judiciously chosen for the small force, it is extremely difficult for the general commanding the superior army to know what number of enemies he has before him. If, not wishing to delay the movement of his army, he deploys too small a force, the defender may use his whole power to inflict a crushing defeat upon this before it can be supported. If, on the other hand, he deploys a force sufficient to destroy the body opposed to him, this must involve a long delay, and very probably he will find, when he moves to attack, that the defensive force is already gone, or has left only some light troops to make a show up to the last. By such means again and again in war a small force employed in well-chosen ground has been able to hamper the movements of a superior body and to gain time for other operations. The different applications of this detaining power of small bodies are so numerous that hardly any problems either of strategy or tactics are intelligible unless its nature is understood. The essence of it lies in the smaller body not allowing itself to become so engaged as to have its organic unity destroyed by defeat.

Interior lines.

The simplest application of this detaining power of small bodies occurs in this way. Suppose, as often happens, that two allied armies, or two parts of the same army, are moving to unite against an enemy. It may happen that by skilful dispositions or the chance of war the general engaged against them is able to interpose between them whilst they are still several marches apart from one another. Suppose now that in a country favorable to such an operation he employs a small portion of his own force to delay the march of one of his opponents, whilst he throws the bulk of his forces against the other. In attempting to defeat this body before it can receive support he holds a position of very great advantage. This is the situation which is commonly described by saying that the general in question is acting on "interior lines" against the two armies opposed to him. But it is vitally important to his success in this matter that he shall succeed in defeating one of his opponents whilst the other is still some marches off, otherwise their union against him on the field of battle may, from the very fact of their striking his position from different directions, prove even more disastrous to him than if he had allowed them to unite before he attacked them. Thus when Napoleon, during the Waterloo campaign, had broken in at Charleroi upon the intended point of concentration of the allied armies, he, with Ney opposing Wellington at Quatre-Bras long before the English army was concentrated, and himself able to act with the bulk of his forces against Blücher at Ligny before the Prussian army was fully concentrated, was acting in the most perfect way upon interior lines. But, when at Waterloo, whilst he was still engaged with Wellington in his front, Blücher broke in upon his flank; though the bulk of the French army was still between its opponents, that was a position of disaster. During the 1866 campaign the Prussians crossed the Bohemian mountains in two separate armies,—one from Silesia under the crown prince, one from Saxony and Prussia under Prince Frederick Charles. Had the army under the Austrian commander Benedek been concentrated in Bohemia, so that, whilst one part of his forces detained either the crown prince or Prince Frederick Charles, the main body had been thrown against the other, the general would have gained all the advantages of interior lines. But, when on the field of Sadowa, whilst Benedek was still fiercely engaged against the army of Frederick Charles in front, the crown prince broke upon his flank, though the Austrian army was still in one sense between the two Prussian armies, it was so only in a sense disastrous for it. This event, in which an army attempting to take advantage of the separation of two opponents is crushed between them on the field of battle, is described by German soldiers by the phrase that such an army is taken "tactically between them" ("in der taktischen Mitte").

The operation of acting on interior lines was the favorite form of Napoleon's strategy. He would have condemned unhesitatingly the attempt to carry out any plan of campaign which involved such a combination as the Prussians attempted in 1866. But in his day armies were not connected by telegraph. In speaking of the concentration of armies prior to a campaign as necessarily made out of reach of a concentrated enemy there is this reservation to be noted. If two armies acting against a third can so nicely time their union as to strike against the enemy on the field of battle within a few hours of one another, they gain all the advantage of getting their enemy "tactically between them." The difficulties, however, of this nice adjustment of time are so great that no prudent commander would deliberately beforehand arrange his general concentration in this way on the field of battle. Nevertheless, the fact that it is sufficient for the armies to have effected their junction so nearly as to be within reach of mutual support on a field of battle considerably enlarges the area within which their union can be accomplished. Thus at the beginning of the 1866 campaign the Prussians had fixed the point of junction of their two armies at Gitchin; but, though it would have been possible for them to have joined their forces on June 30, they did not carry out this actual meeting. They were content with the fact that the two armies were by June 30 in close supporting distance of one another. They only actually met on the field of battle of Sadowa. The effect of the selection of a point of concentration, as tending to leave an enemy uncertain as to the direction which a general purposes afterwards to take, can hardly be better illustrated than by Napoleon's concentration in the Waterloo campaign. By gathering his army at Philippeville, Beaumont, and Solre, he threatened Mons more directly than he threatened Charleroi, and thereby tended to prevent his enemies from concentrating against the point of his intended attack.

Depôts of supplies.

There is a peculiarity in the strategical aspect of British campaigns beyond sea against savage tribes which requires a short explanation. Usually the difficulty lies in transporting from the base towards the front a sufficient quantity of provisions without eating them up on the road. Since the animals and men employed in transporting food and ammunition must themselves be fed, it is evident that if we send supplies for a day's journey forward the balance available for feeding the troops will be the amount the transport can carry, less two days' food for themselves, that is one day forward and one day in coming back. Similarly, for a journey of eight days to the front sixteen days' food for the carrying animals and men will have to be deducted. In fact, more than this will be required, because when the journey is extended beyond a certain limit there must be occasional rest days. It is clear that if, as was the case in Abyssinia, in Ashantee, in the movement on Sikukuni's country, and, though with different transport, on the Nile and in Egypt, a march of many days beyond all supplies of food not carried by the transport has to be made, a point will be reached at which the animals begin to eat up all the food they carry. This can only be met by the system of depôting. That is to say, an accumulation of large supplies of food is made as far forward on the road as possible, and then from that point it is again pushed forward by one relay of transport whilst others fill it up from behind. But here again another point arises. If the whole army to be employed on the expedition were pushed forward to the front where the supplies are being accumulated, these supplies would be eaten up as fast as they arrived. The fewer the troops in the front the more rapid will be the accumulation. Hence the great secret of a rapid advance in this case is to keep in front only as many troops as are necessary, when well entrenched, to guard the accumulation of supplies. The more completely all others are kept back from the front the sooner will the expedition achieve the object for which it is employed. These are incidents which repeat themselves on every English expedition, while at the same time complaints are continually being made of the generals during the course of the campaign for the delay involved in their doing the very thing which hastens achievement.

TACTICS.

In speaking of the changes which have affected strategy, we declared our belief that the *weapons* of strategy have changed since the Napoleonic era even more completely than those of tactics. It now becomes necessary to define the limits of what this statement implies. We have shown how, even in questions of strategy, the spirit of subordination and the nature and kind of co-operation which a minor leader has to give to his commander-in-chief have been affected by the changes in the size of armies, the scope of operations, and the developed facilities of communication and supply. This change, however, of the spirit of organization is, in so far as regards strategy, a comparatively secondary matter. Among the few men engaged in the actual command of armies and army corps, it is almost an affair of personal arrangement and of mutual understanding how far the subordinate acts independently, and how far he merely carries out the precise directions of his superior. Where men are so well known to one another as were, for instance, the leaders of armies and army corps of the Germans during the campaign of 1870, the generals of such great bodies as these could judge from personal knowledge of the characters of those under whom they were acting what degree of latitude to allow themselves in the interpretation of orders. We see the evidence of this everywhere. This personal confidence, this mutual knowledge of one another among the higher leaders of armies, has become an essential instrument of modern war. The general who has men under him whom he does not know and cannot trust suffers now in a degree in which he never suffered before.

But when we come to compare the effect of modern changes on the spirit of strategy, in these matters of discipline, with its effect on tactics, there is no proportion between the two.

Importance of mechanical drill.

Discipline is the very life-blood of an army, and it is on the field of battle, that is, within the province of tactics, that it shows its potency. To interfere in any way with this spirit, as it determines the power of the commander over his men in the presence of the enemy and under the stress of battle, to introduce the least malignant influence into it, is to blood-poison the army. Therefore, as no army can nowadays hope, in presence of a modern enemy armed with the weapons of to-day, to carry out a system of manœuvres in which discipline can be maintained with the old facility, and under conditions so favorable to it as those of the past, we must approach the subject with a caution proportioned to its vital importance. Curiously enough it is from an English scientific author, from Mr. Darwin, that one of the ablest of recent German writers on war has borrowed the penetrating phrase which sums up the essential element, common to the discipline of the past with that of the present, which it is vital to us not to shake or to impair. The engrained habit of mutual confidence among all ranks of a regiment is the factor in its strength which attracted Mr. Darwin's attention as the cause of its incalculable superiority in power over an armed mob. Baron von der Goltz accepts the statement as true, without reserve. When, however, we come to consider what has enabled armies to acquire this engrained habit, we are met by some very curious experiences. In the first place, the instinctive habit of obedience to a word of command, as coming from one who has the right and the duty to give that command, has to be carried into the very limbs of a man. When cultivated men of mature years entered the ranks of the British volunteers during the early stages of the movement, some very amusing protests appeared in print as to the dreary monotony of the mechanical contortions which represent the early phases of recruit drill. A certain pity or sympathy was expressed for the poor soldiers who had to spend their lives in such uninteresting tasks. It would hardly be too much to say that the complaints of these very superior persons showed a want of philosophic acuteness, which is entirely absent from the minds of the most zealous volunteers of our day. No one understands better than these the fact that in the dull mechanical routine of those incidents of recruit drill is laid the foundation of all military power. The zealous barrister, who at thirty-five always found himself turning by mistake to the right when he was ordered to turn to the left, who found it impossible to supple his limbs in the required "extension motions," was unconsciously illustrating the weakness of the most zealous untrained armed man. With the best of wishes his body was so little under the command of his own mind and will that he could not, much as he wished it, place it at once under the command of any one else. Much less could he cut out that disturbing element himself so far as to obey instinctively, and without a certain element of resisting individuality, the command he received.

Further training now necessary.

Now the capacity to act together under the orders of one man can never be dispensed with under any of the conditions of modern war. The instinctive obedience of a rank of soldiers to the order to turn "Right about," when that order sends them back into the ground where shells are bursting and where bullets are raining, has been a power in fighting too great for us ever willingly to throw it away. Some humorous illustrations of its effect on soldiers, and of the victory-winning power which an even apparently unintelligent submission to this authority of instinct has given, more especially to English soldiers, are mentioned in the article ARMY (vol. ii. p. 516). In proportion as men understand war they value this effect, and would be unwilling even to diminish at a given moment actual loss of life if that diminution were secured by any sacrifice of this power. An old English battalion trained to the absolute perfection of such mechanical obedience was a splendid fighting instrument. No training, however perfect, to take advantage of ground, to seek cover, to glide on to the weak points of an enemy, will compensate, even in these days, a deficiency in that habit of utter self-abnegation, of entire subordination to the one purpose of united action under assigned orders. But, under the modern conditions of war, the loss inflicted within a given time by the terrible weapons now in the hands of all armies is so great that the very formations under which on a parade ground the armies of the past prepared to move in actual fighting under the orders of their commanders are mechanically, as much as morally dissolved. Not even can the voice of the captain or the subaltern be heard, much less that of the lieutenant-colonel, above the din of breech-loaders and of shrapnel shells. It is not therefore with a light heart, not willingly, not as thinking that a dispersed order of fight is something in itself more powerful or more advantageous than a rigid formation in which ordered and orderly movement is easy, in which force can be concentrated, in which the habits of discipline can be more certainly maintained, but of dire necessity, that the most experienced soldiers of our day have come to the absolute conviction that only by preparing armies for fighting in dispersed order can discipline be maintained at all. The great problem of modern tactics, in so far as it concerns actual fighting, which regulates everything else, is how to maintain the old unity under the new conditions which make it so difficult.

Infantry.

This much at least we know, that from the moment that infantry are actually involved in a modern breech-loader fight all manœuvring has ceased to be possible. The natural and the necessary deduction from this is that the only influence which can be exercised upon such a fight by any but very subordinate leaders is to throw into it fresh bodies of men who till then have been retained in close formations. Now the experience of the 1870 battles showed clearly that the effect of fresh bodies thus thrown into a fight is very great indeed. Moreover, that experience showed further that the direction in which the fresh force is thrown into a contest already engaged between two bodies of infantry is vitally important in determining how great the effect of the blow so delivered will be. The tendency of any great fight is to break up into a series of partially independent actions. Therefore it almost always happens that in each of these there are on both sides certain weak points, which present opportunities to a skilful assailant. These arise either from circumstances of ground or from the inevitable disconnection produced by isolated action of particular bodies of troops. Skill now consists in taking advantage of these opportunities, in anticipating the conditions under which they are likely to occur, in preparing to escape from similar dangers, and in pressing home a success. Here then is the way in which the organization spoken of above as the means of battle action makes itself felt. It is impossible now for the commander-in-chief of a great army to be ready at each part of a battle for one of these emergencies. Scarcely can the commander of a division of 10,000 men, or even the commander of 3000, meet all the local incidents that occur. At each stage of the hierarchy there is needed a man who, in proportion to the extent of the opportunity or the danger, is ready to seize or to meet it.

But among the means of doing this which the practical experience of the Prussians taught them is one which tends more and more to be forgotten as the experiences of the great campaign are lost in the distance of the past. As the phases of any battle now succeed one another a time comes when the fight sways forward, and many men are left behind out of the immediate region of the combat. Often these stragglers are more numerous than the men engaged in the actual shooting line. They may be in a wood or for some other reason out of the reach of the enemy's projectiles, or they may at all events not be severely exposed to them. What is wanted is to take advantage of this wasted power and to throw it into the fight. This can only be done effectively by getting the men into closed bodies, and so bringing them again under orders and discipline. This was what the Germans—or, to speak more accurately, the Prussians, who in all these respects were head and shoulders over all their German compatriots—habitually did.

The study then of the mode of preparing infantry for the fights of the future does not in these inner circumstances of battle consist in training them for some particular forms of attack nearly so much at least as in the following points:

1. In accustoming the men, as soon as from any cause they find themselves thrown out of the actual fighting line and out of the stress of fire, to place themselves instinctively and as quickly as possible under the orders of some officer who can get them into order, and either lead them on or await the moment when the services of a formed body of men will become invaluable;

2. In accustoming officers to seek all opportunities for reforming dispersed men at the earliest possible moment;

3. In maintaining such close order as is possible as long as it can be maintained without risking overwhelming loss of life and dire confusion,—hence therefore the breaking up into such small organized bodies as, by taking advantage of ground or other means, may be able to preserve unity of action longer than would be possible with greater masses;

4. In keeping up, by the action of the higher ranks of the military hierarchy, the fighting connection between these bodies, by the judicious employment of fresh force or of reserves that have been made up out of men that have been already engaged;

5. In providing for the continual replenishment of ammunition close to the fighting line of at least all those who are not actually engaged in it, and the continually thrusting into the fighting line of men well supplied with ammunition to push forward the line, so that those who have exhausted their ammunition may be resupplied without having to fall back; and

6. Above all, in practice and training during peace in a mode of action which cannot be simply learnt on a parade-ground by help of drill-sergeant and words of command taught by rote.

We have taken first this question of the change which has taken place in infantry fighting, because it is on the forms of infantry fight that the changes in armament have produced their greatest effect, because the main substance of an army always consists of infantry, and because the changes which have occurred in the use of the other arms, artillery and cavalry, have been determined by the changes in infantry tactics and arms more than by any other cause, though the development of artillery armament has also affected them.

Now the danger which faces any British army under present conditions in preparing for modern battle lies in the fact that a long peace following upon the great wars of the end of the last and the beginning of the present century has tended to stereotype forms which were originally based upon the battle experience of the past. There is a dread of change where change is required, because officers and men have come to look upon the great traditions of the past as sacred. In England men wish to follow in the footsteps of the soldiers who acquired an experience under Wellington such as no men since then have had. It is in its essence a sound and healthy feeling. But there is the greatest danger lest names should be put for facts, lest in the very act of servilely copying forms we should ignore altogether the principle which determined the action of our forefathers. They started from the experiences and necessities of the battle-field as these existed in their own day. They based their forms upon those necessities. If we would really imitate them we must in this do as they did. We cannot take their forms based on the battles of their own time, and then work forward from these forms to what we shall do on the battle-field now. We must frankly face the fact that, the character of battles having changed, we must work back from the conditions of our present battle-fields to the peace forms which will prepare our soldiers for them.

Practical work.

Terms under such circumstances become confused. Men talk about the practice of forms in which their life is spent as "practical work." They look upon all experience gathered from the fields where shells actually burst and where infantry firearms are used to kill as "theoretical." The truth is exactly the opposite. Such merit as the older drill at present has is due to certain theoretical considerations which were at one time soundly deduced from practice in the past. The only practical work is that which tends to prepare men, not for the inspection of some general on a parade ground, but for actual war. An army is doing "practical" work in the preparation for its real duty, that of winning battles. It is employed on mischievous theoretical work, on false theory, whenever it is doing anything else.

Control drill.

Now this one thing is certain, that, whereas the great fighting formation of the past for British infantry was the line, that formation can be used no longer in actual fighting against troops armed with modern weapons, unless exceptionally in purely defensive positions, where its trained cohesion is of little importance, because cohesion is in any case easy. All rigid drill is at present based on the assumption that wheels of parts of this line are necessary in order to enable the troops to keep together shoulder to shoulder. What is required is not this, but that we shall obtain by complete organization down to the lowest units a command of fire and a command of groups. Of all the incidents of a modern fight that of which it is the hardest to give any conception to a man who has not seen infantry possessed of the enormous facilities for firing which are supplied by modern arms is the intense absorption in the mere fact of firing, which almost like a catalepsy takes possession of the man who is using his weapon against an enemy, or, as may often happen in close country, against nothing at all. Many of the rifles that were picked up on Majuba Hill were found, at the last moment when the Boers were closing, sighted to 800 yards. It is noted as a quite remarkable instance of presence of mind on the part of a Prussian sergeant during the attack on St. Privat, that he personally took care that the men reduced their sights to the proper range as they advanced. Now this illustrates perfectly the kind of trained habit which we need by our modern drill to induce in men in action. We want to educate men so that they do not fire under the conditions of a catalepsy. Now experience has shown that this can only be done by having men who are not themselves firing trained to look after those who are firing, so that the fire may be regulated, effective, and deliberate. The men themselves must be trained to fire only under orders, and not under the influence of a tendency to fire merely to relieve their feelings. We cannot put better what is involved in these necessities than in the following words of Colonel J. H. A. Macdonald of the Queen's Edinburgh Rifle Volunteer Brigade :

> "How is this to be done? How but by so regularly, consistently, and persistently putting the soldier through the action of firing by orders that it shall be a second nature to fire his rifle only under control of his superior, and not otherwise. What is wanted is the conviction in the mind of every instructor, from the highest to the lowest, that his men should never leave a parade without having gained something in fire discipline,—that is, that fire control drill be one of the main points in view as a necessary part of the work to be performed on every occasion when men are being drilled, exercised, or inspected, from the moment that they know the rifle exercises until the day when they leave the service. Let some of the time which formerly was spent in a perpetual *form* drill, to produce a military machine that had a steadiness in formation which nothing could shake, be now spent in producing by a perpetual *control* drill a firing organism which shall have a steadiness in the use of fire which nothing can shake. The troops that shall be found most in the hands of the commander in the matter of fire will, *cæteris paribus*, be invincible."[1]

But in order that we may secure this end it is essential that the organization be carried down to the smallest groups within a company, and our drill must be adapted to deliver such groups as methodically and regularly as possible within the zone of fighting.

It does not appear that any adequate experiments have as yet been made to determine the means by which this can best be done. Experiments during peace time are in no sense wholly satisfactory. In order that they may be worked out properly they require to be watched at every stage by men who have closely studied the experiences of modern war, and know what has been done by other armies, who have learned from those experiences not slavishly to copy what was done by men who were themselves experimenting under the dread conditions of actual warfare, but to extract from them sound lessons for future guidance. To quote again from Colonel Macdonald.

> "Would it not be wise to do what is done in other departments of military science, and give some facility for practical and exhaustive experiment? In all other departments practical experiment goes merrily and expensively on. Thousands of pounds are spent on a gun which penetrates another inch or two of armor. New and thicker plates are rolled. A new 'Big Will' is built, and again crashes through the armor with its first shot, and perhaps blows off its own muzzle with the second. Treasure-devouring sea monsters are built superseding one another at short intervals. Torpedoes, torpedo boats, and machine guns are subjected to crucial experiments. But from the nature of the material with which experiment has to be conducted in the case of the most important land fighting machine—the infantry—the circumstances are exactly reversed. Experiment would cost nothing; but, while inventors can experiment in armor metal, gun building, and rifling and explosives, before offering appliances to the Government, there can be no practical experiment with the only material out of which the infantry machine of war is made without order from authority. It is only by leave of the state, through its officers, that any proposals to improve the working can be tested, and—as is the case in all inventions—not only tested, but developed and improved by experiment. Almost all successful invention is the result of alternate thought and experiment. There is also the further difficulty that the proposers of tactical improvements are not independent men, but servants of the owners of the material. They cannot consistently with discipline proceed as other inventors are able to do. They cannot canvass higher officials, or exert extraneous influence. They may not use the soldiers who happen to be under their control as material for experiment.
>
> "Further, even if it be permitted to them to exhibit these ideas experimentally, the material with which they must do so is not dead material, plastic and absolutely passive. They have to test their invention with materials which have been turned into a machine already on a different system, and have therefore a way of working which unconsciously at first militates against the display to the best advantage of the new idea."

These conclusions appear unanswerable. Though, for the reasons which are implied in the very sentences we have quoted, we are not as yet prepared absolutely to advocate any specific system, it appears to us that the method of working which has been suggested by Col. Macdonald promises such valuable results that it ought at least to be fairly tried on a large scale. It has received the warmest possible support from the best infantry soldiers of the English army—from Lord Wolseley, from Sir Donald Stewart, and many more. It has been approved in principle by many others, who have not had the opportunity of examining its practice. It has been successfully tried and experimented upon so far as peace-trials go, both at home and in the colonies, and has been greatly appreciated by those who have tried it. It consists in a method of permanently arranging a company in four ranks, so that from these the successive bodies of firing line supports and reserves may be successively sent forward. It has several important recommendations. It limits the front of a captain's command. By forming groups of eight men of those who stand side by side in the fours it carries organization down to the lowest point, while it tends to bind together, by the principle of comradeship, the supports who successively arrive to the men who are in front. By making this comradeship apply to those who form the two adjacent groups of four of the company when in line, it ought certainly to facilitate the re-formation of the company. At present if one man is lost in the front rank of a company, the whole have to be numbered again in order to enable it to form in a column of fours at all. On Col. Macdonald's system each group of eight being fixed, the company can be fitted together by the gathering of these groups in any order, so long as all are in their proper places within their own group of eight.

In any case, going back once more to the experience of the past, we are now at a time in these matters very like that which preceded the Peninsular War. The drill which was employed in the Peninsula was in all essentials worked out by Sir John Moore in a series of experiments conducted at the camp of Shorncliffe. No more important results were ever obtained by peace-training for war than those which were deduced from these experimental exercises. If we really reverence the great soldiers of the Peninsula, this is the way in which we shall honor them. We shall not do what they did not, we shall not accept from the traditions of the past forms which are not adapted to actual warfare. We shall not write drill books in the study or the bureau, and force field movements into conformity with them. We shall employ for the work of our great camps of exercise generals who have made an exhaustive study of the present conditions of warfare, and staff-officers who can assist them in their work. We shall experimentally try "those suggestions which have upon them any reasonably good stamp of approval by military men of skill." We shall really and crucially investigate them, "with opportunity afforded to proposers to meet difficulties that may be suggested." "Those proposals which can be defended from serious theoretical objections should be submitted to a few months' experiment in selected regiments, and reported on as to their practical working in the essential points of simplicity and uniformity of manœuvre, adaptability to circumstances arising, maintenance of order, retention of unity of commands, rapid recovery of exact tactical form, and fire control. Then let authority take what is best, it may be adopting here one detail and there another."[1]

---

[1] *Common Sense on Parade, or Drill without Stays* (p. 118), by Colonel the Right Hon. J. H. A. Macdonald, C.B., M.P., 1886.

The Russians at one time adopted and abandoned a system of working by groups of four. So far as we are able to perceive, Colonel Macdonald's system is not open to the objection which led the Russians to abandon their method of fours. They found that, when they had formed their groups under a "father" who became the leader, the men were so much attached to one another that as soon as one was wounded all remained with him, so that every time the enemy wounded one man four were put *hors de combat*. It is clear, on the one hand, that this is an objection that would not present itself in mere peace practice at all, so that the necessity for criticism applied at the time from actual experience of fighting shows itself forcibly. On the other hand, it by no means follows that the difficulty would not be overcome by such a closer association of groups as Colonel Macdonald's system appears to promise, and by a trained habit of trusting that the wounded will be properly cared for by the men assigned for that purpose, and a knowledge that the business of all those who are able to continue the fight is to ensure the safety of the wounded by securing victory.

It will be obvious from what we have already said that we do not believe that any army in Europe has as yet solved the question of the most effective mode of delivering infantry within the area of modern fight, and that nevertheless we believe that data now exist from which, with proper experiments, a method might be adopted which would at least give to that army which adopted it incalculable advantages in the earlier battles of a modern war. The one point that must be thoroughly realized is that the firearm of the present day has become the determining weapon, for the development of the efficiency of which all tactics must prepare the way.

That brings us to another matter of vital importance. As long as the shock tactics of the past were possible, the neat drills of the parade grounds were the essence of soldiering, and therefore, when a few rifle regiments at first, and afterwards the army generally, had liberty to practice shooting, that was looked upon as an accidental and exceptional thing unconnected with the real business of the soldier, and therefore with his everyday life. This unfortunate divorce between the work at the butts and on the manœuvre-ground, once established in the habits of an army, cannot for many years be cured. It exists still. Yet every manœuvre in which careless aiming, careless expenditure of ammunition, and wrongly adjusted sights are permitted is a direct injury to the fighting efficiency of the force which manœuvres. Nothing else can compensate for the evil so done. Good shooting, and movements tending to give to good shooting and good weapons the greatest possible advantage, are next to a healthy morale the essence of modern fight.

Nevertheless it is the training of the spirit of an army, the bringing home to all ranks of the objects now to be aimed at, that is the difficulty in all these matters. The very strength and power of discipline in its formation and engraining of habits is that which makes an army so hard to deal with when habits have to be changed.

In the present condition of the tactical question it has seemed to us essential to devote so much space and pains to the enforcing of these points that we can only lightly touch on several questions that have been most eagerly discussed in relation to infantry tactics.

Long-range and reserved fire.

The question of long-range fire against reserved fire is mainly a question between material and moral effect. It seems no doubt a strange thing, when we have enormously increased the range of modern weapons, that we should throw away that advantage, and allow an enemy without firing a shot at him to pass over a large area of ground where we could inflict loss on him. Undoubtedly, in so far as we can train picked shots to fire at long ranges, so as to disturb the movements of columns, and to interfere with artillery, it is well worth our while to do so. But with the utmost training that we can give them the mass of men in the ranks of an army never will become good shots at long ranges. Almost all fire, therefore, at long ranges becomes unaimed fire, and an enemy can to a great extent avoid exposing himself on the ground where the fortuitous rain of bullets is falling. Meantime the mere fact of firing having begun puts the troops who are firing almost beyond the reach of orders. Their own excitement and the noise together make it most difficult to give them any directions. Sights that have been fixed for the long range are not changed to the short. The fact that, despite all their efforts, the enemy continues to advance demoralizes them, and despite his losses encourages him. These are considerations which are not taken into account in the arguments of those who base their conclusions merely on the amount of loss which may be inflicted at very long ranges. Yet, at all events up to 1877, they had in actual fighting proved supreme. It may be the case that a very highly trained army, using long-range volley firing under effective control, might produce such loss upon an enemy approaching that it would make his actual attack upon a position impossible. What is certain is that, up to 1877, there had been no experience in war which proved that such long-ranged fire was as effective as fire carefully reserved for the ranges within which infantry can use their arm with the greatest effect.

Such at all events was the experience of the 1870 campaign, and it confirmed the experience of previous wars in certain respects which, as will have been seen from the above account, depend rather on the condition of men's minds than on the efficiency of weapons. Both, however, in the German army and in the French an immense impression was produced by the incidents of the attack on Plevna. There is no doubt that there the certainly unaimed fire of the Turks produced an enormous effect. Skobeleff, when he had at last succeeded in reaching the "Green Hill" in one of his own most brilliant efforts, found that there were no troops behind the slender line of skirmishers whom he had actually with him. All his reserves had melted away under the storm of bullets. If this experience could be accepted as representing a normal phase of a modern battle, the conclusion would be inevitable that so long as there are ample supplies of ammunition the effect of long-range fire may be so great as to be decisive. It would be madness altogether to reject such an experience. Where analogous conditions occur no doubt a better regulated long-range fire is too important an element of power to be ignored. But it is necessary to realize what the conditions were. In the first place, the whole attack was one that never ought to have been made. It never would have been made had not the commanding archduke overridden the advice of all the best soldiers he had, and in mere obstinacy and ignorance dashed his men against a position that ought never to have been so assailed. It was an attempt of a field army against what had almost become a fortress. The Russians were unsupported by any adequate artillery for its reduction. The ground was unusually open and exposed to the full range of the Turkish fire. The Russians showed here just the same incapacity for taking advantage of ground, so far as the smaller groups were concerned, which they had shown in the Crimea. They huddled together in great masses, more unwieldy than any regular column, but just as much exposed to unaimed fire. There was therefore nothing to show that a properly conducted skirmishing attack might not have found means of reaching the position which Skobeleff actually secured.

---

[1] Colonel Macdonald, as above, p. 127.

Nevertheless, when all these allowances have been made, and while it seems as important as ever to realize what advantages the sudden effect of reserved fire may secure, the fact remains that under certain very possible conditions of fighting an extensive employment of long-range fire may be advisable, and it is therefore right that every army should prepare for such an event.

For instance, in an attack on the *forts d'arrêt* with which the French have covered their frontier, it is extremely probable that the Germans, being close to their own magazines, and therefore able to employ a practically unlimited amount of ammunition, will overwhelm these places with long-range infantry as well as with artillery fire. There is no doubt that their infantry has been practiced in firing volleys at very long range, and for such purposes it would be certainly comparatively easy to ensure the delivery of actual volleys. It may even be the case that in defensive positions, where the extent of ground open to view is considerable, long-range infantry fire regulated by volleys may be attempted. We cannot, however, see how it would be possible to attempt this during an attack unless one special body of troops be assigned for the work of long-range fire, in order to occupy the attention of the enemy while other forces advance to the attack. On the one hand, the discipline of the French army was so loose during the campaign of 1870 that it is quite possible that long-range fire might be much better brought under control than it was by them; on the other, it is emphatically necessary to assert that the difficulties involved in a free employment of long-range fire are not merely those of an adequate supply of ammunition, but that those considerations to which we have drawn attention must be taken into account. If an army is sufficiently well in hand for the choice between long-range fire and reserved fire to be in the option of the general who commands, then undoubtedly cases will arise when each may be used with advantage. Certainly it would not be a wise or safe thing for an army to enter the field without having ever practiced the regulated fire by volleys at long range against an army which had practiced it. It is clear that the tendency in that case would be for the unpracticed to indulge in much unregulated long-range firing. With an army trained to both methods of action, the general who realizes the risks and advantages of either will be able to exercise a sounder choice than the man who has become an inveterate pleader for either system, and cannot therefore adapt himself to the cases that arise.

Volley firing.

The general question of volley firing as against individual shooting is independent of the special use of volleys for very long-range shooting to which we have above referred. It may obviously be possible to ensure the regular delivery of volleys at very long ranges, such as the French are now practicing, 3000 yards or more, without its being possible to do so in anything that can properly be called an engaged fight. The effect produced by a well-delivered volley is out of all proportion great as compared with the effect of isolated shots. Moreover, it is a curious fact that apparently men aim better when they fire together than when they fire each by himself one after another. It is constantly found at the butts that the greatest number of shots has been delivered by the "best volley," that is, the one in which all the arms go off most like one. But it is a matter of great doubt whether in war it is practically possible under most circumstances to deliver a volley at all. Captain May, the author of the "tactical retrospect" on the 1866 campaign, denied that any volleys had been fired in that campaign. The cases of its employment in the 1870 campaign, which are sufficiently established not to fall under such criticism as he applied to the nominal volleys of 1866, are not very numerous. We may leave the question with the remark that the moral effect produced by a volley is too great for the attempt to use it ever to be willingly thrown away, but that it would be now rash to take for granted that on service the best troops can be depended on to deliver during close fighting accurate volleys, unless it be in small parties. The possibility of even the fire of groups is disputed by Von der Goltz. It is obvious that, if he be correct in this respect, all attempt at regulating fire in action is

> "An effort only and a noble aim,
> Still to be sought for, never to be won."

We incline to think that all war experience tends to this conclusion, and it is a reservation which we must therefore append to our cordial agreement with the passages we have quoted from Colonel Macdonald.

Cavalry.

Of all tactical facts, the one which needs most study for practical purposes is the relation of the size of men, on foot, mounted, in mass, and in different formations, to the undulations and features of ground. There is nothing which the untrained eye so little realizes as the extent to which concealment and cover for men, even for mounted men, exists on the apparently most level plain. This fact, which is important for both the other arms, is for cavalry vital to its present use. Nothing is more certain than that under the present condition of arms cavalry cannot successfully assail in front either artillery or infantry in any formation in which the artillery or infantry are able to use their arms and can observe the approach of cavalry over long distances.

On the other hand, cavalry striking by sudden surprise on the flank of unprepared infantry or artillery, engaged with other enemies, may produce an effect, great to an extent of which as yet we have no adequate example in modern war. That is the conclusion drawn from their own experiences of the 1870 campaign by the most experienced leaders who were employed in it. Count Von Moltke in 1882, and Prince Kraft of Hohenlohe-Ingelfingen in his letters on cavalry published in 1887, have alike pronounced decisively on the subject, and it would be easy to show that the whole weight of the best military opinion in all countries except Russia is on the same side.

The practical possibility on most fields of battle of cavalry being thus employed depends on two facts,—on the one hand the extent to which almost all ground presents opportunities to a skilful leader for moving his men unobserved from point to point of a great battle-field, and on the other that absorption in the intense excitement of a modern fight which prevents men from observing what is taking place anywhere beyond the immediate range of their own employment.

It follows from this that the utmost possible skill in the handling of cavalry as a mounted arm will be required if cavalry is to take advantage of such chances as modern fight will present to it. Now, in all periods since the invention of firearms, there has been a tendency, as improvement in weapons has taken place, to attempt to put cavalry on a level in point of firearms with the infantry with which it has had to contend. Invariably, when that rare development of armies, a great cavalry leader, has arisen, he has swept away all attempts of the kind, and has employed his cavalry with their proper weapon, the "arme blanche," sword or lance.

The reason of this is easy to explain, and the explanation is one that shows that the principle is as applicable to the present condition of warfare as to any preceding one. The effective action of cavalry as cavalry depends on ruse, on surprise, on skilful manœuvring, and on the impetuous power and moral effect of the man and horse, glued to one another as though they together formed the old ideal of the arm, the centaur. Now, the dash and vigor with which an actual cavalry charge takes place depends on the moral condition of that part of the centaur in whose hands it is the great purpose and effect of high training to place the guiding of the composite animal. Never has it been possible to train a great body of fighting men in two opposite directions at once. Balanced judgment, and an appreciation of the powers and uses of each part of the force he has to employ, are the duties of a general. But if a body of infantry, dispersed in scattered groups, or isolated men, are to repel successfully a body of charging cavalry, they must have acquired sufficient sang-froid to calmly fire at the great and overwhelming avalanche which they see moving down on them. To that end they must have acquired confidence in their weapon, the firearm, and must have learnt to believe that its power is so great that it gives them plenty of time to bring down the mighty-looking horseman before he closes with them. Similarly, if cavalry is successfully to be led by skilful manœuvring into a fight where firearms are creating the most horrible appearance of danger, they must have acquired a confidence in the skill of their leaders, in their own power of combined action, and in the effects of their sudden appearance, which will carry them on though leaders fall, and though death and destruction seem to await them. In other words, they must have learnt to despise the firearm when pitted against their own skill in evading its danger and in delivering home their blows. All attempts, therefore, to train cavalry not to employ their skill in manœuvring as the weapon to which they trust, but, on the contrary, to be always ready to jump off their horses and begin firing, tends directly to weaken and destroy the very spirit and quality on which the efficiency of true cavalry depends.

Now, the great leaders to whom we have referred believe absolutely in the possibility of true cavalry, properly trained, being able to play its part on the field of battle. Prince Kraft's 7th letter on this subject is so admirable in its analysis of past experience that all who would understand the subject should study it in its integrity. His conclusion is—"From all that I have stated in this long letter I draw the conclusion that cavalry will, in the future, also be able to play a decisive part in battle if they can be led in such a manner that they can break out round a flank, and can thus, up to the last moment, take advantage of the fire effect of their own line of battle. But to do so will sometimes require from the cavalry that they shall be able to advance as much as four miles, at a rapid pace, before they deliver their charge."[1]

Mounted infantry.

There is, however, another necessity of modern warfare which is altogether distinct from the question of supplying firearms to cavalry in order to make up to them for the increased power of infantry. Powerful as modern infantry is, it is very slow in its movements. It is very difficult for a general to have it at the very place where he wants it. Hence the idea of mounting infantry and of sending them forward either on horseback or in carts, or where there are numerous roads on bicycles and tricyles, is one that is of the greatest importance. The so-called cavalry of the American civil war were all of this character.[2] Most of them had been accustomed to rifle-shooting from their childhood and could ride. They had had no opportunity whatever of acquiring the manœuvring facilities of European cavalry. Probably European cavalry would have been altogether unsuited to the country in which they had to work. The essential condition of the efficiency of mounted infantry, which these men in fact were, is that, while they can ride well enough to get over such ground as is required, they waste no time in learning manœuvres which they could not master, but look altogether to fighting with firearms and on foot whenever collision becomes necessary. The Boers represented an almost ideal body of this kind. British wars have supplied most valuable bodies of mounted infantry, who have been always picked men, picked shots, and excellent infantry. As a general principle, it is safe to say that they ought to be under infantry and not under cavalry officers, as to their immediate command—though very often indeed they will be a most valuable auxiliary for any cavalry commander, who will in that case of course have the whole body under his orders. In so far as their presence tends to save cavalry from the disastrous necessity which occasionally befalls them of having to employ their men in fighting on foot, their presence with cavalry is always valuable. But, as the time when all their best training is required is when they are actually fighting on foot, it is far better that they should then find themselves under the orders of an officer whose training tends to make him accustomed to handling men on foot, rather than to one all whose experience ought to have accustomed him to handle men on horseback, and to hate making them jump off their horses.

The difficulty in enforcing these principles lies in the fact that it is only the experience of war on a large scale which brings home to cavalry officers the disastrous consequences of injuring their own power by continually trying to take up the rôle of mounted infantry. They find themselves at peace manœuvres continually put *hors de combat*, because they have come under the fire of infantry. They can very often get into positions where, if they were infantry and in large numbers, their effect would be most telling. Their rapidity of movement enables them to do this. A narrow deduction from a very incomplete knowledge of the experiences of cavalry charges during the 1870 campaign led to the conclusion that cavalry could not be employed on a modern battle-field in their proper work. That conclusion is utterly rejected by all those authorities who have had the best means of analyzing the experiences on which it was based ; yet it remains a tradition which unfortunately affects the minds of many cavalry officers as well as those of many other officers in the army.

It is safe to say, in conclusion on this matter, that the two forces of cavalry and mounted infantry are each of the greatest value, provided they each adhere to their own proper function. As soon as mounted infantry begins to attempt manœuvres on horseback it necessarily becomes a very inferior cavalry. As soon as cavalry takes to dismounting, its equipment, its training, and usually its arms are sure to make it into a very inefficient body. Every year adds to the necessity of high shooting training for infantry, and of every hour of their work being connected with the efficient use of their arm. Every hour devoted by cavalry to shooting which subtracts anything from training in their own proper work, or which leads them to compete with the other arm in that way, weakens them. By no process can they compete with infantry if they measure themselves with them under the conditions favorable to infantry fighting. Nothing is more fallacious than the notion that because during the latter part of the 1870 campaign the German cavalry often fought on foot the Germans therefore consider that the proper employment of the arm.

[2] [The first modern bicycle to appear in America was imported in 1876, and the American manufacture began in 1878. They were unknown in the armies of the civil war. During that war the cavalry on both sides was a regularly organized arm of the service, although it often fought dismounted and was reinforced by mounted infantry.—AM. ED.]

Prince Kraft emphatically says—"The circumstances of the latter campaigns of this war were so abnormal that no rules for the employment of the arms can be deduced from them." "No cavalry could perform the duty" the German cavalry here did, of saving their own infantry by acting on the wings against the French infantry, "except in the case where they were engaged with an enemy whose hastily collected and undrilled masses had not the full value of regular troops."

We may also mention as an illustration of at least the views of the German leaders that during some manœuvres in 1879 a regiment of lancers by sudden surprise charged from behind some rising ground at four battalions of infantry, who did not see the cavalry till these were on their flank at a distance of 200 yards already in full charge. Scarcely a shot was fired before the cavalry were among the infantry. The emperor and Count Von Moltke were present, and the decision was that three battalions were *hors de combat.* Now, when it is remembered that a cavalry regiment numbers about 400 men and three battalions about 3000, the difference between the effect produced under such circumstances by a body of cavalry and an equivalent body of mounted infantry, who could not have dismounted at most more than 300 men, who would certainly have been destroyed, is too great not to be realized. In this case an instance occurred of what Prince Kraft mentions as a possibility continually illustrated by the experiences of the 1870 campaign. The colonel commanding the lancers, having moved personally to a well-chosen spot, had been quietly observing the movements of the infantry, himself unseen up to the moment when by a signal he gave the order for his regiment to advance at a gallop, and then charge.

Artillery.

Here the first point it is necessary to insist on is that the tendency to a divorce between firing practice and drill manœuvre has been inherited by the artillery from the past as it has been by the infantry. Napoleon's formation for the battle of Austerlitz placed his artillery guns between his infantry brigades and on their flank. The artillery advanced nearly in line with the infantry and rather in advance of it. As long as it was possible for artillery thus to move up to close quarters with the infantry, exact accuracy of fire training was of little importance. The distance was so short that the round shot were bound to produce their effect. But, when the range of both infantry and artillery fire were greatly extended, a change took place which required a change of habit in the artillery, for which the long training of the past had as little prepared them as had been the case with the infantry. The horse artillery, and at a much later date the field batteries, had acquired a mobility which enabled them very rapidly to take up assigned positions. But the habit of thinking that drill movements, irrespective of accuracy of fire, were the business on which a soldier's mind should be set continued to operate long after all idea of moving artillery cheek by jowl with infantry or cavalry had been abandoned. The practice grounds of artillery for actual shell fire are necessarily much fewer and more difficult to select than the ranges for infantry. Hence what we have said of the tendency in infantry manœuvres to separate the effective fire of the ranges and the butts from drill and manœuvres applies with tenfold force to the artillery. Moreover, in the case of the artillery this tendency has been aggravated by a certain fear among generals and their staff officers of interfering in the detail work of a special arm. As long as a battery is seen to manœuvre rapidly, to take up an assigned and telling position, and to fire off a puff of smoke, the superintending general is apt to think that he may assume that all has been done that ought to have been done.

Unfortunately, it may happen that the battery which thus appears to have acted in the very smartest possible way may have all the time been learning to do just what will injure it for war service. Nothing is more noteworthy throughout the 1870 campaign than the extraordinary superiority of the German artillery over the French. There were no doubt certain technical reasons for this; but by far the most important reasons were these: (1) the German batteries had been trained habitually so to co-operate that a French battery almost always found itself opposed to a German brigade of six batteries when it came to fighting; and (2) at all their manœuvres the Germans had been training for war, while the French artillery had not. The German artillery had never fired off a gun which had not been properly laid at an assigned object, with the range determined, the nature of the projectile declared, and the fuse to burst the shell so far fixed that, had it been necessary actually to fire in earnest, every man would have gone through an almost exactly similar experience. The French, on the other hand, had piqued themselves on their dashing battery manœuvres, and had been content to fire off a blank cartridge as rapidly as possible, no matter how the gun was laid, or what would have happened about the shell.

The same two schools at this moment exist among British artillery officers. The unfortunate tendency at present is for the officer commanding a battery who tells his subalterns, "Never mind how you fire; get off a puff of smoke, just to show where you are," to *seem* much smarter than the man who insists upon every gun being properly laid at an assigned object, and on having every possible condition fulfilled as it would be in war. The general who at a mile's distance sees the two puffs of smoke cannot tell the difference, though, if he rode into the battery which has so promptly puffed off its smoke, he would probably find that one gun was inclined high in air and the next shooting into the ground ten paces in front of the muzzle. It is not too much to say that this latter battery has been in every respect acquiring inefficiency by the day's work. It will be slow when it comes to action, because the men have never been trained to be as quick as the circumstances of action permit, have acquired no practice in rapidity under those conditions. It will have acquired no practice in actual shooting except its few annual shots on the practice ground, which are sure with it to have been regarded as a most inconvenient interruption to the show drill and show manœuvres on which it has been employed throughout the year. This is the point of artillery tactics without which everything else is utterly valueless. As Prince Kraft of Hohenlohe-Ingelfingen puts it, "The artillery must in the first place *hit*, in the second place *hit*, and in the third place *hit.*"

It depends far more in England upon generals commanding districts and divisions and on their staffs than upon artillery officers whether this result is attained or not. It is almost impossible for the most zealous artillery officer to keep up the confidence and spirits of his battery and to keep their work to the proper level if on every occasion they find that, because he insists on work being properly done, some other battery which is amusing itself with sham firing gets all the credit of superior smartness. The matter is therefore vital to the efficiency of this arm of the service. The infantry and cavalry will find in action that they rely on the support of a broken reed if the artillery generally has not brought the most efficient technical and practice-ground work into the closest relation with field manœuvring. Given that this has been done in the sense here described, Prince Kraft's next condition may be briefly stated, because its importance will be easily understood. "It must next be in a condition to come into position at the right moment, and, with this object it must practice itself in getting over distances of many miles, and even forced marches of a day or so, at rapid pace. If," he adds,[1] "it can satisfy these claims, it will give us everything which is needed as to its fitness for employment in battle."

Massed artillery fire.

So far we have spoken of conditions in which the tactical necessities of modern artillery are very similar to those of modern infantry. In the next point the contrast is as sharp as the analogy was close in the former instance. Infantry, as we have seen, once committed to a fight, is beyond the control of all officers not actually leading them at the time. Artillery under all but the rarest circumstances can be almost as easily moved from one point to another of a battle-field, out of action in which it is fiercely engaged, as if it were not employed in firing at all. Therefore the rule is now accepted in all armies that every gun that can be employed should as soon as possible be brought to bear on the enemy. The shorter time artillery is limbered up and the longer it is employed in action the more effective is its work. With a very large army Prince Kraft, whose authority on such a subject is probably the highest we have, makes a rather hesitating exception in this sense that ordinarily the commander-in-chief of a very large army will have whole army corps designed for a particular work, usually for striking at the decisive point of a field of battle. With these their own artillery will naturally move. But so far as artillery is available on any part of a field of action, even including that of divisions and army corps kept back from the actual fight, as long as these are stationary, every possible gun will be pushed forward. The altogether overwhelming effect of a concentrated and massed artillery fire is so enormous that whatever tends to increase the number of guns employed tends to give that superiority over the enemy's artillery which it is one of a general's first objects to secure.

Ordinarily a battle will now begin by artillery opening fire at a range which is fixed by the necessity of the attacking artillery not exposing itself during the time that it is coming up to the enemy's effective fire with shrapnel shell. This is reckoned at about 3800 yards. From that point the artillery, as soon as it has been able sufficiently to occupy the fire of the enemy to make further advance possible, pushes in to a distance of from 2200 yards to 2700 yards. Infantry in the meantime will have been pushed on sufficiently to protect the ground thus to be occupied by the artillery from direct attacks from the enemy. At this point an artillery duel is practically the certain beginning of the regular battle. The artillery will fire at any of the other arms as soon as it is able to bring any effective fire to bear on them. It is no easy matter for infantry to attack other infantry until the artillery has prepared the way for them by a heavy fire. But the artillery will hardly ever be able to do this until it has established such an ascendency over the enemy's artillery that the latter is either silenced or at least temporarily withdrawn.

Regulation battery fire.

No matter how great the mass of artillery that is gathered together, Prince Kraft, basing his conclusions upon the soundest reasoning, condemns altogether the independent fire of individual guns within a battery, and, unless exceptionally for the purpose of ascertaining a range, all salvoes of artillery by batteries or otherwise. Nothing is gained in point of the number of shell that can be thrown in a given time by firing battery salvoes instead of firing steadily gun by gun from the flank of a battery. After a salvo an interval of from 36 to 48 seconds at least is required before another can be fired, while with very rapid firing from the flank an interval of from 6 to 8 seconds allows a shell to traverse a range of from 2500 to 3000 yards, so that the effect of each shell can be seen.[2] The effect of this is to enable the officer commanding the battery to have his fire under control, and to induce much more careful firing by each gun. Indeed, if a German battery is seen to be firing, not from the flank but irregularly, it may be taken for granted that it is being mastered by the hostile fire, and is out of hand.

Supply of ammunition.

The duty of each commanding officer of a battery is to be continually watching over the replenishment of his ammunition, and therefore as long as possible to draw upon his wagons for ammunition, keeping the ammunition in his limbers as a last reserve. If this cannot be done, the limbers must be filled up as rapidly as possible. If, however, by misfortune all ammunition is exhausted, the artillery must not retire, but must, for the sake of the moral effect, remain without firing rather than produce the encouragement to the enemy and discouragement to their own troops of withdrawing without express orders.

Summary.

We shall complete this sketch of the duties of artillery in action by quoting the following summary from Prince Kraft of Hohenlohe-Ingelfingen:

On the Offensive.—(*a*) Artillery, after it has silenced the enemy's artillery, must not as a rule approach nearer than from 1600 to 1700 yards to infantry of the enemy which is as yet intact and is not engaged with other troops. (*b*) If the enemy's infantry is held in check by another force of artillery, or by infantry, it is not only advisable, but it is the duty of artillery to advance to a range of from 1100 to 1200 yards. (*c*) At the most decisive moment of the action artillery must not shun the very closest range. (*d*) As soon as the main attack has proved successful, the artillery must hasten up to secure the captured position by its fire; at such a moment, its proper place, in most cases, is in the line of skirmishers.

On the Defensive.—(*a*) The normal post for artillery in a defensive position (though this may be modified by the character of the ground) is 500 yards in the rear of the foremost infantry position, provided always that the latter leaves the field of fire of the artillery open. (*b*) Artillery must never abandon its position, even if the enemy come up to the muzzles of the guns, unless the officer commanding the troops has given orders for a general retreat. But this does not imply that artillery, acting on the defensive, are forbidden, if the assailant begins to get the advantage in the artillery duel, to cease firing for a time, and to withdraw their guns under cover, with the object of suddenly coming into action again at the most critical moment. (*c*) If the order to retreat is given, the only possible moment at which it can be commenced is either when the enemy has not yet advanced to the attack, or when he is preparing a second attack after having been repulsed in the first.

Horse Artillery in a Cavalry Action.—(*a*) As a rule horse artillery should go in at once to a decisive range for the artillery duel, since the considerations which compel artillery when engaged with infantry to fight at longer ranges lose their force in this case, owing to the speed at which cavalry can move. From this position it will silence the enemy's artillery, and immediately afterwards, or as soon as it can see them, it will turn its fire on the enemy's cavalry. (*b*) During the charge of its own cavalry it will fire on that of the enemy, or, if that be not possible, on his artillery. If it has nothing to fire at, it will remain in position with loaded guns (common shell and not shrapnel should be used), in order, in case of the failure of the charge, to give support to its retiring cavalry, and to show them where they are to rally. (*c*) The horse artillery requires a special escort on that flank of its position only on which the cavalry fight is not taking place, and even there it requires it merely for the purpose of scouting; a section will therefore be sufficient. (*d*) If the charge succeeds, the horse artillery must gallop up to the spot where it took place, in order to secure its possession with their fire, and to assist in the pursuit.

---

[1] We quote from his correspondent's summary of his views, and from the translation given by Major Walford, R.A. These words occur in the 17th letter, *Royal Artillery Institution Proceedings*, August, 1887, p. 187.

[2] See the prince's 15th letter, *Royal Artillery Institution Proceedings*, p. 171.

The Combined Action of the Three Arms.

So far we have spoken of what may properly be called the minor tactics of the three arms, though that name is often applied in quite a different sense. There can be little doubt that it is in that portion of tactics that the complexity and difficulty of the present stage of the question lie. As regards the larger handling of armies, the tendency of recent wars has been rather to simplification than to increased difficulty. The employment of artillery in great masses, never in isolated batteries, is, so far as that arm is concerned, its most important law. So much so is this the case that, even when as many as eighty-four guns were collected together at Wörth, the Germans found it answer best to turn all of them at once upon a single French battery, and then upon another, and so on. Whenever possible, some at least of the guns will take up an enfilading position; that is, they will fire from flank to flank of the troops they assail, in preference to firing directly at them. It is always advantageous to the fire of artillery to have great depth rather than great extent to fire at, because range is much more difficult to fix correctly than direction.

Prince Kraft regards it as doubtful whether artillery can be employed in crossing its fire, the right of a long line of guns firing at an enemy's right and the left at the left, which would give to each a certain advantage in the direction of their fire. But it is clear that, if the whole of a long line of guns be employed, as at Wörth, first against one object and then against another, many of the batteries will not be firing directly to their front, but at an angle, sometimes a very sharp one, to their own front.

Normal course of a modern battle.

In any case the earlier stages of a modern battle are sure to begin with a heavy fire of artillery, following either on some slight affairs of outposts or on the cavalry having ascertained the position of the enemy at least approximately. Then may perhaps follow, what we have already suggested as one of the alternatives, a carefully regulated long-range fire of infantry; then probably a gradual development of the infantry of the assailing army in front of the position to be attacked and certain tentative movements designed to feel the strength of an enemy's position. Then, as soon as the point to be carried at any cost has been determined on, every effort will be made to distract the enemy's attention from this, to occupy him at other points, and by engaging him all along the line to prevent him from reinforcing the point which it is essential to carry. At present the attempt will be, when possible, almost certainly to attack a flank. But, as the necessity of this becomes thoroughly realized as it now is on both sides, and a tendency arises towards continual extension of the space occupied in order to meet outflanking movements, it is almost certain that on one side or other the extension will exceed the limits of defensive power, and that then blows will be struck with the object of breaking the too extended line. All the cavalry not employed in mere reconnoitring duties, or for keeping up the connection between different parts of the army, will ordinarily be kept under the control of the commander-in-chief until he is able to define the part of the battle in which it can be most effectually used. Then, when he has so far decided its direction, he will be obliged to leave all details to the cavalry leader, who will choose his own time and opportunity for delivering his blow. The local defensive power conferred by the present arms will be used on both sides. The assailant will endeavor by employing it at unimportant parts of his line to gain the advantage of the superiority of force necessary for striking at the decisive point. The defendant will naturally employ it to the full. Both on one side and the other, however, the effort will be to keep strong forces of all arms for the decisive period of the action.

So far as Continental warfare is concerned, the enormous development of modern armies makes it very uncertain how far elaborate strokes of tactical skill can ever again be delivered in the way they were by Napoleon,—for instance, at Austerlitz and Dresden. The experience of recent wars supplies us at all events with nothing of the kind. The enormous masses and the enormous extent of ground to be covered almost force a general into the simplest possible arrangements on the larger scale, leaving it to his subordinates to work out the development with such local skill as the circumstances permit. Nevertheless, it would be rash to say that, as incidents of a great campaign, many battles may not be fought, the effect of which on the conduct of the general operations will be very decisive, where comparatively small numbers are engaged. For the conduct of these at least there are many lessons to be gathered from the tactical experiences of earlier wars.

Choice of position.

In the taking up of positions it may be assumed generally that the conditions to be sought are freedom for manœuvre, free scope for fire both of artillery and infantry, and, as a rule, for that end gentle glacis slopes like that of St. Privat and Gravelotte, rather than precipitous heights like that of the Red Hill at Spicheren. There is nothing as to which war experience and popular assumptions differ more than as to the relative strength of different positions. As a rule, steep heights give a great deal of cover from fire. Their lower slopes can only be seen from the edge, and that edge cannot be held because it is completely exposed to the enemy's fire from many points below. It is better to have a difficult climb than to be shot by a bullet. It has constantly happened that positions have fallen because the defenders have trusted to physical difficulties of access rather than to the effect of ground upon the use of arms for their defence. Whatever tends to oblige an enemy to debouch on a narrow front against a wide front of fire is most valuable to the defence; but it is upon considerations like these of the use of arms that the strength of a position must be determined. Similarly, whatever tends to facilitate communication between one part and another of your own troops, and to cause an enemy to separate his, adds greatly to the strength of your position. The element of time also has here, as in the province of strategy, to be always taken into account. Where ground tends to make movements slow and difficult, there it will be safe to economize men by employing small forces, in order to gain time for decisive blows in other directions. Whatever in an enemy's rear will prevent his safe retreat, and therefore either locally or throughout a position will make successful attack decisive, is greatly in favor of the army which, whether at first on the defensive or offensive, can attack an enemy in such a position. The application of these principles is almost infinite in its variety. It is impossible here to do more than indicate their general character.

Provision against outflanking movements.

The proposition has been advanced that it would be best to meet the effort of an assailant to outflank a position by employing detached bodies to manœuvre outside the position, so that when an assailant has committed himself to an outflanking movement, and has moved up his enveloping troops, the detached body could fall upon these unexpectedly from their rear. Twice during the 1870 campaign the Germans designed a movement of this kind. In neither case was there an opportunity for putting it to the test. Such a movement successfully executed could hardly fail to have great results. On the other hand, a well-handled cavalry, searching all the country round prior to an action, might not improbably discover the isolated corps placed for the purpose, and in that case it ought not to be difficult for the assailant to keep it apart from the main army and to destroy it.

A proposal of a somewhat kindred kind, but involving a different principle, was made by Sir E. Hamley as a deduction from the 1870 campaign, and was applied in practice by the Russians in Asia in 1877. He suggested that the defensive strength of comparatively small bodies was now so great that a general would be tempted to detach, or to connect with his main body only by a telegraphic wire, a body of troops, who, passing round an enemy to be attacked, should take up a strong position in his rear, and should thus become the anvil on which the main assailing army should act as hammer, grinding the enemy between them to powder. This was actually done by the Russians, who in October, 1877, destroyed Moukhtar Pasha's army by this very means.

Both these forms of operation—the detached force to the flank and the detached force to the rear—partake of the nature of the attempt of Napoleon to destroy the allied armies, after the battle of Dresden in 1813, by previously detaching Vandamme to intercept their retreat. As a matter of fact, that manœuvre was one of the most disastrous that Napoleon ever attempted, but the disaster was probably due to a failure of Napoleon's own wonted activity arising from illness. The telegraph might then have made a very great difference in the result of the operation. In any case, these suggestions indicate possibilities of action, due to the present condition of arms and of science, which may have much wider application in the hands of skilful commanders. Everything will depend on their execution, and on the skill with which they are met. It may at least be asserted that, with the possibilities of such manœuvres being employed against him, it will ordinarily be extremely rash for a general to commit himself to the actual turning movement by which he wheels up a portion of his army to attack an exposed flank, without having searched the ground with his cavalry far beyond the point which he proposes to assail. This was actually done by the German cavalry under express orders from headquarters, prior to and during the great turning movement at the battle of Gravelotte.

Marches.

Marches.—The principles regulating the marches of armies which precede battles are determined by the conditions of a modern battle itself. As a rule nowadays the cavalry of an army will be certainly pushed far forward in advance of the main body. Therefore, with the exception of small parties of horsemen employed as orderlies, for keeping up the connection between one part of an army and another, and to aid the infantry in the immediate work of local security, the marching body will in ordinary country consist of artillery and infantry. The tendency for every action to begin by artillery fire continually leads more and more to the pushing forward of that arm to the front of the column, only sufficient infantry being placed before it on the road to give protection in case of sudden attack, and to furnish the necessary troops for the defence of the guns at the beginning of an action. The exact order of march will therefore necessarily vary with the character of the country through which the army moves. In very mountainous districts, in which collision with an enemy may occur at any moment, it may be necessary to push forward infantry instead of cavalry. In all cases where mountain defiles have to be passed, detached infantry must gain possession of the heights before the main body enters the defile.

Since the great object of all marches is to deliver the army in fighting order on the battle-field, it is necessary that the force should not be dispersed too widely on the march, but it is quite as necessary with large bodies of troops that the march should not be made upon too few roads. An army corps with its attendant wagons occupies in depth about 25 miles on a single road. As under most circumstances a day's march is about 13 or 14 miles, it is clear that, if an army corps were moving in the ordinary road formation on a single road, the rear of the column would scarcely be able to arrive on the same day that the head of the column was first involved in action. Nor is it always possible to place the whole of the fighting force in front and to leave the whole mass of wagons in rear. Ambulances and surgeons at least, as well as ammunition columns, are required at the very moment of battle. Therefore it is advisable to employ as many roads as possible that are within convenient reach of one another. The difference between the lengths of march that have been done by troops under favorable and unfavorable conditions is so great that it is impossible to fix any specific length as the march that can under all circumstances be relied on. Good spirits, good roads, high training, and favorable weather on the one hand, and depression, deep mud, storms, and want of marching condition on the other, are elements that must be taken into account in all such matters. Of the difficulties which a large number of troops marching on a single road encounter a striking illustration is afforded by an incident of the 1866 campaign. According to the Austrian official account, the men marched eight abreast in order to diminish the length of road occupied. Yet, though this unusually wide marching front was taken up by the infantry, and corresponding formations were as far as possible taken by the other arms, the length of the longest column, according to Von der Goltz, was, when actually on the road, from front to rear 67½ miles in length. In this case about three corps were marching together. Hence it is always desirable when possible to allow one road at least to each division. Another striking illustration both of the size of modern armies and of the length occupied by troops on a road is given by Von der Goltz. He calculates that, if the present German army were placed on one road, it would reach from Mainz to the Russian frontier, the whole distance being densely packed with men, guns, and wagons. Again, he shows that either the present French or German army extended in battle array would occupy the entire length of the common frontier of the countries.

Advanced and rear guards.

Advanced and Rear Guards.—The question involved in the proper use and employment of advanced and rear guards would occupy more space than we can possibly afford for them. In general terms it may be said that, with both advanced and rear guards, artillery (perhaps with machine and quick-firing guns), cavalry, and mounted infantry will play the principal parts. It is tolerably certain, though opinion is much divided on the subject, that the enormous advanced guards employed by the Germans during the 1870 campaign, in which the advanced guard of an army corps sometimes consisted of about half the whole force, would be for most campaigns a mistake. The tendency of very large advanced guards is, as that campaign showed, to bring on actions prematurely. Artillery or mounted corps can be easily drawn out of a premature action. Infantry cannot be so withdrawn. If the advanced guard is large enough to give time to the marching body to form upon suitable ground before it is attacked, it possesses all the strength that is necessary.

The task of a rear guard retiring before a victorious enemy, and covering the retreat of a beaten army, is one of the most delicate of operations. It depends for its proper execution on the full employment of those means for gaining time by forcing an enemy to deploy on unfavorable ground which have been described under the general heading.

Outposts.

Outposts.—The subject of outposts is also one which, for its full explanation, would require a volume to itself. The general principle on which their use is based is that a slender cordon of men shall so surround an army when at rest that no enemy can approach its quarters unobserved, and that this cordon shall be supported by pickets from which the actual sentries for the cordon are taken, and these again by stronger but less numerous bodies, serving to connect together the different parts, so that, if the enemy attempts to drive in the outposts at any point, he meets with a continually increasing resistance. In this broad indication of the method, the principle is equally applicable to cavalry and to infantry outposts. In general, however, the security of a modern army, when not in actual contact with an enemy preparatory to battle, depends chiefly on the early information gained by cavalry pushed far out beyond the rest of the army. The cavalry will be at a distance of at least one or two days' march in advance and on the flanks scouring the country in all directions.

It is practically certain that during the earlier stages of a campaign the collisions that will occur will be between bodies of cavalry pushed forward from both sides, supported by horse artillery and by such infantry as can be rapidly transported to the front. The circumstances of the collision of the main armies must depend in the first instance upon what happens in these encounters, in which cavalry will be the most important arm. Both sides will endeavor to use their cavalry to obtain all the information they can and to prevent the enemy from obtaining information of their own movements. At the same time, in the case of two great neighboring powers like France and Germany, it is probable that attempts will be made by the cavalry on both sides to interfere with the mobilization of the armies across the frontier. These efforts promise to result in contests on a scale and of a kind such as we have never yet seen, and of the nature of which it is difficult to judge from any past experience of war. It seems certain, however, that the body which will gain victory in these encounters will be the most highly trained and numerous cavalry, supported by its sister arm the horse artillery. But the value of a body of mounted infantry, and perhaps a strong force of cyclists, pushed forward to support the cavalry, can hardly be doubted when it is remembered how often defiles will have to be seized, bridges held, and important stations permanently secured. No doubt, when such infantry is not available, cavalry will at times have to be employed on foot for these purposes. So long as such employment is looked on as exceptional and a necessity to be regretted, it need do no harm. In any case no rules must prevent the securing of the actual object for the time being.

Reconnaissance and intelligence.

Reconnaissance and Intelligence.—The vital necessity of obtaining all possible information of what an enemy is doing makes the reconnaissances continually carried out by cavalry all around an army, and the occasional special reconnaissances conducted by single officers and small parties or strong bodies employed for the purpose, some of the most important operations of war. It is, however, difficult in brief space to lay down rules for their guidance, because the essence of the value of such work depends on officers being trained in all parts of the art of war so as to know what to look for and what to report. The principles of such reconnaissance are determined by the general principles of both strategy and tactics, and are not in themselves independent. Nevertheless, it is very important that it should be realized, by men who are sending in reports from some one point of a large circle, that information in itself apparently unimportant may be of the greatest value when it is collated with other facts either already known or simultaneously gathered from other quarters. Thus, for instance, a newspaper advertisement, or a reference to a particular man or officer as not being with his regiment, may give negative evidence of the position of that regiment which may become of great importance. The sifting, therefore, of information should be chiefly left to the department at headquarters which has charge of that work. Spies and deserters will supply evidence the value of which usually depends on the power of the department to check their assertions by a number of minute facts already known. Any information about the enemy or the country which may assist to that end should be carefully gathered and reported. Numerous forms and rules have been drawn up to supply hints as to the kind of information about roads, rivers, railways, villages, etc., which should be gathered. Lord Wolseley's *Pocket-Book* and Colonel Harrison's *Handbook* are the best for these purposes.

Literature.—The following books may be recommended as the most recent and most valuable on matters of military art. (1) On tactics, to which modern military literature has been chiefly devoted, see Prince Kraft of Hohenlohe-Ingelfingen's *Letters* on cavalry, infantry, and artillery, especially those on the last-named. These are being now translated in the *Proceedings* of the Royal Artillery Institution. (2) On cavalry tactics two anonymous works by the same writer appeared in Germany in 1884; *Die Kavallerie Division als Schlachtenkörper*, and *Ueber die Bewaffnung, Ausbildung, und Verwendung der Reiterei.* The former has been translated into French in the *Revue de Cavalerie* of successive months of 1885–86, and we have no hesitation in saying that it is a book that ought to be known to every officer of every arm of the service, but more especially to every cavalry officer. See also *Das Volk in Waffen* ("The Nation in Arms"), by Baron von der Goltz, which has been completely translated into French under the title of *La Nation armée—organisation militaire et grande tactique modernes* (1884); parts of it have been translated by Sir Lumley Graham in the *Journal* of the United Service Institution, No. 138, vol. xxxi. (1887). (3) On infantry tactics the books are legion. They should be read in conjunction with the actual history of the battles on which their conclusions are based, and if possible with a study of them on the ground on which they were fought. Perhaps the most important are Von Scherff's *Studien zu neuen Infanterie-Taktik* (1873), translated by Sir Lumley Graham, *New Tactics of Infantry*, 1875; Verdy du Vernois's *Studien über Felddienst* (1886), and his *Studien über Truppen-Führung* (1873–75), and the numerous strategical and tactical studies recently published in Germany,—many by Von Gizycki, and in some cases translated as we have noted above by Captain Spenser Wilkinson, and published by the Manchester Tactical Society. We should also recommend a perusal of Col. the Right Hon. J. H. A. Macdonald's *Common Sense on Parade* (1886), from which we have given several extracts. (4) On strategy Prince Kraft's "strategical letters" have already been alluded to. Sir Edward Hamley's *Operations of War* (4th ed., 1878) remains without a rival in the English language on questions of strategy. We cannot think that Clausewitz's great book, *On War*, translated by Col. J. J. Graham, 1873, has ceased to be of value. Mekler's *Taktik*, which represents the course for the German war school, has not as yet been translated; it is a most important work. No soldier can read Major Adams's *Great Campaigns* without advantage. But on these matters we must conclude by expressing our conviction that an exhaustive study of at least a single campaign carried out pretty nearly on the principles laid down, for the purposes of the study of general history, by Dr. Arnold, in his *Lectures on History*, but with just such modifications as apply to war study, is almost indispensable to a soldier who would derive much value from those books which examine the whole field of war, and that that cultivation of the judgment of which we have spoken must follow, if any real use is to be made of either one or the other. (J. F. M*.)

NAVAL STRATEGY AND TACTICS.

The introduction of steam, armor, the torpedo, and other modern changes must necessarily have produced modification in naval strategy and tactics since the days of the last great naval war. In the course of the last eighty years wars on land, both in Europe and elsewhere, have been frequent, and soldiers have thus been enabled to keep pace with modern inventions, and to accommodate their strategy and tactics to the ever-changing conditions of the problem. But since 1805, when Great Britain, by her crowning victory of Trafalgar, placed herself in undisputed command of the seas, and, having rendered herself superior to all possible combinations against her, was thus enabled to found unmolested her unrivalled colonial empire, the world has seen no naval war of sufficient magnitude to enable seamen to lay down maxims of strategy and tactics founded on actual experience. It does not follow, however, that we must necessarily give up the problems as insoluble; we are entitled to reason by analogy. The lessons of history, if not followed too slavishly, will act as a useful guide; and when we have made due allowance for the superseding of sail by steam power, and the consequent limits to the mobility of all fighting ships dependent on their supply of coal, when we have taken into consideration the cutting of the Suez Canal and the possibility of another through Panama, and when we have given due weight to the possession by various nations of certain strategic points on the surface of the globe where coal may be obtained, we shall be able to construct some not altogether imaginary theories of future naval strategy, and shall probably find that the problem, at least as between Great Britain and her maritime rivals, bears a striking family resemblance to that which presented itself in the past. The geographical factors are not greatly altered. Some new naval powers have sprung into existence, and must be taken account of, whilst some of those which figured conspicuously in the beginning of the century have dwindled into insignificance; but the relative interests of the two great maritime rivals, Great Britain and France, are practically unchanged.

Strategy.

Strategy.—The great continental powers of Europe, in consequence of their land frontiers, have to depend mainly on their armies to defend their position, and maintain their independence, and they have all been constrained to adopt a system of forced military service, and to support great standing armies, with prodigious reserves, and vast stores of war material constantly at hand. For them the problems with which we are now dealing are questions of minor importance, and must be held entirely subordinate to their military requirements. Italy is probably the only one of them which has reason to fear invasion by sea, or descents and raids upon her extended coast line; and she has lately been making gigantic efforts to supply herself with a powerful war navy, though she is still far behind France, the only power from whom she has any cause to apprehend attack. To Great Britain alone of the great powers of Europe are the problems of naval strategy of paramount importance. Upon a thorough knowledge and just appreciation of them, with a sufficient provision of physical force to secure their successful development in her own interests, depends the existence of the British Empire.

Strategic problems of paramount importance to Great Britain.

The two primary factors which must decide the future naval strategy of Great Britain are the command of the English Channel and the protection of her mercantile marine. Upon the former depends her own safety from invasion, or from partial but disastrous raids upon her open commercial cities and coast towns; and upon the latter depends the no less vital consideration of the uninterrupted supply of food and of raw material for manufacture.

Her naval supremacy in the Mediterranean is of vast importance, for upon it will depend the freedom of her principal route to India and Australia, and also the eventual retention of Malta, Gibraltar, and Cyprus, and of that priceless possession vaguely termed naval prestige, upon which alone she can found a claim to be classed amongst the great powers of Europe. But, notwithstanding the importance to Great Britain of being able to hold her own in the Mediterranean, either with or without allies, in the event of a war with France, or with France and Russia combined, it cannot be considered as vital to the existence of the empire; and it is possible to conceive circumstances in which she might be driven from that sea, or for strategic reasons be induced temporarily to withdraw her ships, and yet, if she could keep open her alternative trade route by the Cape of Good Hope, and protect her food supplies from America, she might secure time to develop her unrivalled maritime resources, and eventually, notwithstanding the enormous temporary loss of prestige, regain her wonted supremacy on all seas.

The naval strategy of the past was necessarily a somewhat inexact and haphazard business. The fact that fleets had to depend entirely for locomotion upon the fickle and uncertain power of wind rendered it impossible to form accurate schemes of combination, and thus the most carefully planned expeditions and enterprises were often frustrated and rendered abortive almost at the moment of consummation by a foul wind or storm. All this is now changed; the present development of steam-power renders fleets practically independent of wind, and even storms can only slightly affect them. The limit to their range of operations dependent on their coal supply, with the question of the possibility of replenishing, adds another element of certainty to the data upon which we can form accurate calculations as to the power and mobility of fleets. It has become possible, therefore, to say that naval strategy is no longer the inexact and haphazard business, depending largely on chance, which it was of old, but an accurate and most interesting science, worthy of the close attention and practical study of the most skilled experts.

The two principal objects of the naval strategy of Great Britain—the command of the narrow seas around her coasts, and the protection of her mercantile marine—are to a certain extent different, though not actually independent of each other. Thus she might, by providing an overwhelming fleet of iron-clads, and neglecting to build a sufficiency of fast cruisers, retain undisputed command of the narrow seas, and yet have her commerce swept off the ocean by an enemy provided with numerous fast, far-ranging cruisers; and on the other hand, it would be useless for her to provide vast numbers of vessels of the latter class to protect her commerce all over the world, if by neglecting her iron-clads she lost command of the narrow seas, and saw her merchant ships captured in sight of their ports. It is obvious, therefore, that her only safety depends upon an ample supply of both.

Blockade of enemy's ports.

The naval strategy of the last war may be briefly but comprehensively described as a blockade of the enemy's ports. The question which now exercises the minds of seamen is whether blockade is at present possible, and if so under what conditions; and the conclusion which seems to have been arrived at by the ablest naval strategists of the present day appears to be that a close blockade, carried on under the old system, is, for various reasons, no longer possible. What is now practicable is observation, or watching by a chain of look-out vessels in connection with a superior fleet, in such a way that the squadron in port would be masked (to use a military term), or in other words, that they would be unable to leave the port without the extreme probability of being obliged to meet and engage with a superior force. The distance at which the masking fleet should remain from the blockaded port, and the question whether they should be kept under weigh, or at anchor at some suitable anchorage, are points of detail which come more under the head of tactics, and must be decided in each individual case in accordance with local circumstances, and with such considerations as the prospect of the blockading fleet being or not being subjected to the attacks of torpedo boats and coast defenders, which, although not strictly speaking sea-going vessels, are yet capable of exercising potent energies within a certain zone of their port, by selecting the most suitable time and weather for their operations. Such considerations render it obvious that the blockading ships must greatly exceed the sea-going force in the port blockaded, as they render themselves liable to all sorts of subsidiary but very effective attacks from comparatively insignificant forces, which, in consequence of their own distance from their base of operations, they would be unable to reply to in a similar manner. If the blockading force is to be kept constantly under weigh, its numbers must be still further increased, as in that case a certain proportion of the ships, variously estimated at from one-sixth to one-third, must be continually absent from their station for the purpose of replenishing their coal supply, and of making those repairs to machinery which are incidental to steamships kept constantly under weigh.

Swift cruisers.

The effective blockade of an enemy's ports would of itself provide for the protection of commerce, for if no hostile ships could escape there would be nothing to prey upon the commerce. Such experience, however, as was gained during the American civil war, supported by numerous peace trials and general nautical experience on the subject, tends to show that a perfectly effectual blockade is impossible, as against steamers; some vessels of high speed will certainly find means of escaping on dark nights or during thick weather, so that it becomes necessary for a rich commercial nation, whose merchant ships cover every sea, to make arrangements for providing at least two cruisers of superior speed and greater coal endurance, to look after every one of the hostile raiders which may escape the blockade and endeavor to adopt the tactics of the famous "Alabama." Some half dozen Confederate cruisers of feeble power and insignificant speed succeeded in driving the merchant flag of the United States off the ocean, and deprived that country of the large share of the carrying trade of the world which it then possessed. A similar disaster to Great Britain in her present unique position would, it is almost superfluous to point out, have far wider consequences.

Some high political authorities have given it as their opinion that no fleet of fast cruisers which it would be possible to provide would suffice for the protection of Great Britain's commerce in case of war with a maritime power. This may or may not be the case, but it is a view not generally shared by the highest naval authorities, who take into consideration the possession by Great Britain of the principal coaling stations of the world.

A novel but apparently not unpractical proposition has been made by one of the ablest and most thoughtful admirals of the British navy, with a view to prevent the wholesale transfer of the mercantile marine to a neutral flag on the outbreak of war with a maritime power. It is to the effect that the national exchequer should guarantee to make good all war losses, provided owners conformed to a few simple but not too harassing regulations as to routes and times of sailing, to be laid down by the Admiralty from time to time. It is quite possible that the call on the national purse might be enormous, perhaps a hundred millions sterling during the first six months of the war; but no mulct it would be reasonable to conceive would equal the amount of the indirect national loss, which would accrue from the wholesale transfer of the carrying trade of the country to a foreign flag.

The subject is worthy of the attentive consideration of all those who essay to deal with the great questions of naval strategy, as the protection of the mercantile marine of the country from either direct or indirect destruction is one of the principal factors in the problem.

Changes in naval tactics.

Tactics.—If naval strategy has been modified by the recent inventions and alterations in warlike materials and the motive power of ships, it is certain that the same causes have had a still greater effect upon all preconceived notions of naval tactics.

Weather gauge will no longer be sought for as an advantage. In fact in all cases of attack by surprise, such as an assault by torpedo boats, or other light craft for the purpose of harassing a fleet, the attacking force would certainly approach from the leeward, by which tactics the smoke from every gun fired by the fleet would act as a screen to hide their movements, and protect them from machine gun fire; for not even the beams of the electric light can penetrate smoke.

A large amount of speculative writing has lately been indulged in, by both English and French writers, as to the naval tactics of the future. We hear of "ramming tactics," "the end-on attack," the "melée," and various other somewhat vague phrases, used to express the views of theorists as to the probable tactics of a future naval battle; and whilst the torpedoist tells us that his weapon (meaning the locomotive torpedo) will certainly decide an action, and forbid ships to approach near enough for ramming, the artillerist laughs to scorn the inaccuracy and limited range of torpedoes moving in such a dense medium as water, and maintains that his weapon, of far greater accuracy, almost equal destructive power, and immensely greater range, will as of old decide the battle.

It is probable that all three weapons, ram, gun, and torpedo, will play a part in future naval battles, though many thoughtful and practical seamen seem to be coming to the conclusion that the ram will not be deliberately used, except perhaps to give the *coup de grace* to a ship with her engines already disabled; and this even would appear to be a wanton destruction of a ship which might become a valuable prize, and an inhuman sacrifice of lives no longer capable of exercising any material influence on the battle.

Ramming.

It seems to be thought that ramming when it takes place in action will be as often accidental as deliberate; and indeed the present high speed and great size and weight of iron-clads would probably forbid practical seamen from adopting that mode of attack. Two ships of from ten to thirteen thousand tons, meeting end-on at a speed of 28 knots an hour (assuming the speed of each to be 14 knots), would certainly produce mutual destruction, with loss of the lives of almost all on board, and it seems difficult to believe that any two men who still retain calm judgment and reason would deliberately adopt such a suicidal method of fighting, if indeed it be possible to steer two large ships at high speed with such accuracy as to cause a direct collision,—a point which many practical seamen doubt.

On the other hand, a ship striking another on the broadside, or at any angle approaching a right angle, would probably cause the destruction of the latter, with but trifling injury to herself, supposing her bows to be properly constructed for ramming; but, in order to place a ship in a situation to strike such a blow (both ships proceeding at speed), she would herself have to assume a very critical position; that is to say, she would have to expose her broadside, or in other words, she would have to place herself almost as much across the assumed path of her adversary as the adversary was across hers; in which position the miscalculation of a few seconds in time, a knot or two in speed, or even a small touch of the helm of either ship at the last moment, would turn the would-be rammer into the victim. It is probable therefore that, if ramming takes place in action, it will be more frequently by accident than design.

Much has been made by the advocates of ramming tactics of the incident of the battle at Lissa, where the Austrian wooden ship "Ferdinand Max" rammed and sank the Italian iron-clad "Re d'Italia"; but it has been stated on high authority that the brave Tegethoff himself has disclaimed any preconceived design in the matter, further than that he suddenly observed through the smoke a gray object in front of him, which he took to be an enemy, that he ordered his ship's engines to be put "full speed a-head" and his ship to be steered for the object, and that he then found he had rammed and sunk the "Re d'Italia."

In some instances modern ships have been designed and built with a view to carrying out some special plan of tactics. Thus in the British navy several ships have been built for the "end-on attack," as it is called, a somewhat vague term for expressing the desire of some officers to fight their ships end-on to the enemy, —tactics, however, which can only be consistently carried out if the enemy consents to run away; otherwise it is evident that, if both ships continue to advance towards each other, they will meet, and if they do not strike and sink each other, they must pass from the "end-on" to the "broadside-on," then "stern-on," and then, unless they mutually agree to run away from each other, they must pass through the "broadside-on" position again before they resume the "end-on" or bow attack.

It would seem therefore to be wise not to construct the ordinary battle ships for any particular method of attack, whilst the whole subject is in such an untried and speculative condition, and so much necessarily depends on the tactics of the enemy, but rather to make ships as strong all over, both offensively and defensively, as it is possible to do upon a given displacement and at a certain cost.

Tactical formation.

The principal tactical formations for modern fleets are—single column in line ahead; two and three columns in line ahead; the same in line abreast; quarter line or line of bearing; indented line; and the group formation. In the last-named, a group of three ships becomes the tactical unit instead of the single ship; there is a leader with a ship on each quarter at different angles and different distances; and in this, and also in the indented line formation, the object is to keep the broadsides of the ships open or clear of consorts; but, in consequence of the more recent battle ships not being built specially with a view to broadside fire, these somewhat complicated formations are not generally popular.

Science and the ingenuity of inventors are day by day adding fresh weapons of more terribly destructive energy to the already prodigious list of war material, and the attack may be said to keep always well ahead of the defence, so that it becomes more difficult to lay down fixed rules for tactics than for strategy. Much will depend upon the personal genius, nerve, and happy inspirations of the individual admirals and captains who first find themselves engaged in a modern naval battle; and national instincts, and practical experience in handling steam ships at high speed, will count for much towards the issue. (C. C. P. F.)

WARANGAL, or WORUNGUL, an ancient town in the Nizam's Dominions, or Hyderabad state, situated 86 miles northeast of Hyderabad city, in 17° 58′ N. lat. and 79° 40′ E. long., and containing in 1881 a population of 3347. It was the ancient capital of the Hindu kingdom of Telingána, founded by the Narapati Andhras, of which now little remains to denote its former grandeur except the four gateways of the temple of Siva. These are still in a state of tolerable preservation.

WARASDIN. See VARASD.

WARBLER, in ornithology, the name bestowed in 1773 by Pennant (*Genera of Birds*, p. 35)[1] on the birds removed, in 1769, by Scopoli from the Linnæan genus *Motacilla* (*cf.* WAGTAIL) to one founded and called by him *Sylvia*,—the last being a word employed by several of the older writers in an indefinite way,—that is to say, on all the species of *Motacilla* which were not Wagtails. "Warbler" has long been used by English technical writers as the equivalent of *Sylvia*, and consequently generally applied to all members of the Family *Sylviidæ* thereon raised, which has since been so much subdivided as to include a vast number of genera, while species almost innumerable have from time to time been referred to it.

Until recently ornithologists had come to agree pretty well as to which forms should be considered to belong to the Family *Sylviidæ*,—the "American Warblers" (*Mniotiltidæ*), to be presently considered, being therefrom segregated; but some writers, seeing the difficulty of separating the remainder from the *Turdidæ* (*cf.* THRUSH), tried to get over it by proposing to erect an intermediate Family for the WHEATEAR (*q.v.*) and some similar forms, under the name *Saxicolidæ*. In truth the difficulty was thereby doubled, for, if it was before hard to distinguish between *Sylviidæ* and *Turdidæ*, it has since become harder to distinguish on the one hand between *Sylviidæ* and *Saxicolidæ*, and on the other between *Saxicolidæ* and *Turdidæ*. The confusion thus caused is chiefly due to the adoption in a more or less modified form of the views put forth by Sundevall in 1872, and revised by him in 1874 (*cf.* ORNITHOLOGY, vol. xviii. p. 41–43). For him, however, it is to be said that he at least proceeded in a fashion that had long been recognized, and gave reasons, whether good or bad, for the system he propounded; but his imitators have omitted so obvious a requirement, and leave to any one who would use their results the task of discovering how they have been reached. Hence it has been suggested that some of the alterations introduced since Sundevall's time have been purely arbitrary, if indeed they did not proceed from considerations of personal convenience, or occasionally even through mischance. Still the greatest allowance must be made for those who attempt to reduce to order such a multitudinous assemblage of forms—forms which present an almost endless variety of small differentiating characters, pointing in numerous directions—while the essential structure of all is apparently so similar that at present there is no hope of assistance from the anatomist or the morphologist. But the affinity, seeming or real, to the *Turdidæ* does not offer the only difficulty. The resemblance which some other forms, often placed with the *Sylviidæ*, bear to the *Timeliidæ*[2]—the *Crateropodidæ* of some systematists—is equally if not more puzzling. It is admitted by many systematists that the *Timeliidæ* form a group that has been made a "refuge for the destitute," a group into which the genera and species that were troublesome to classify have been thrust; and, as a natural consequence, the limits of such a "Family" or group have scarcely been plausibly defined.[3] It appears that the so-called *Timeliidæ* lead off to other groups, as the *Laniidæ* (*cf.* SHRIKE) and what not, and their existence as a separate "Family" can hardly be taken for a certainty. Again a small group of birds, almost wholly peculiar to the Australian region, have been sometimes separated as *Maluridæ*, and of these more must be said presently. Lastly, there are certain genera that, though formerly included without hesitation among the *Sylviidæ*, have lately been designated "Fly-catchers," on grounds, however, that have not been explained.

To deal with this theme in satisfactory detail would require far more space than can here be allowed, for the failures of later systematists would have to be shown by a series of minute criticisms of a kind that would be only acceptable to specialists, and hardly understood by others than experts. All things then considered, it would seem to be best for our present purpose to regard the "Warblers"—without pledging our faith to the recognition of a "Family" *Sylviidæ*—from the point of view which obtained before the more recent and perplexing (because ill-defined) opinions were introduced, and that aspect is afforded by the scheme furnished by Canon Tristram to Mr. Wallace, and by him adopted in his *Geographical Distribution of Animals* (ii. pp. 257–260); but our limits will only allow us to touch upon a few of the most prominent members in addition to those which have already been or will form the subject of separate articles. In this sense then the first that may be mentioned are those forming a group of more or less aquatic habit, usually called *Calamoherpinæ* but more correctly *Acrocephalinæ*, the commonest of which in England is the well-known Sedgebird or Sedge-Warbler, *Acrocephalus schœnobænus*, whose chattering song resounds in summer time from almost every wet ditch in most parts of Britain. As is the case with so many of its allies, the skulking habits of the bird cause it to be far more often heard than seen; but with a little patience, it may be generally observed flitting about the uppermost twigs of the bushes it frequents, and its mottled back and the yellowish-white streak over its eye serve to distinguish it from its ally the Reed-Wren or Reed-Warbler, *A. streperus*, which is clad in a wholly mouse-colored suit. But this last can also be recognized by its different song, and comparatively seldom does it stray from the reed-beds which are its favorite haunts. In them generally it builds one of the most beautiful of nests, made of the seed-branches of the reed and long grass, wound horizontally round and round so as to include in its substance the living stems of three or four reeds, between which it is suspended at a convenient height above the water, and the structure is so deep that the eggs do not roll out when its props are shaken by the wind. Of very similar habits is the Reed-Thrush or Great Reed-Warbler, *A. arundinaceus*, a loud-voiced species, abundant on the Continent but very rarely straying to England. Much interest also attaches to the species known as Savi's Warbler, *A. luscinioides*, which was only recognized as a constant inhabitant of the Fen-district of England a few years before its haunts were destroyed by drainage. The last example known to have been obtained in this country was killed in 1856. The nest of this species is peculiar, placed on the ground and formed of the blades of a species of *Glyceria* so skilfully entwined as to be a very permanent structure, and it is a curious fact that its nests were well known to the sedge-cutters of the district which it most frequented, as those of a bird with which they were unacquainted, long before the builder was recognized by naturalists. In coloration the bird somewhat resembles a Nightingale (whence its specific name), and its song differs from that of any of those before mentioned, being a long smooth trill, pitched higher but possessing more tone than that of the Grasshopper-Warbler, *A. nævius*—the *Salicaria locustella* of many authors—which is a widely-distributed species throughout the British Isles, not only limited to marshy sites, but affecting also dry soils, inhabiting indifferently many kinds of places where there is tangled and thick herbage, heather or brushwood. In those parts of England where it was formerly most abundant it was known as the Reeler or Reel-bird, from its song resembling the whirring noise of the reel at one time used by the spinners of wool. The precise determination of this bird—the Grasshopper Lark, as it was long called in books, though its notes if once heard can never be mistaken for those of a grasshopper or cricket, and it has no affinity to the Larks—as an English species, is due to the discernment of Gilbert White in 1768. In its habits it is one of the most retiring of birds, keeping in the closest shelter, so that it may be within a very short distance of an eager naturalist without his being able to see it,—the olive-color streaked with dark brown, of its upper plumage helping to make it invisible. The nest is very artfully concealed in the thickest herbage. The foreign forms of Aquatic Warblers are far too numerous to be here mentioned.

In the scheme already mentioned, a Subfamily *Drymœcinæ*, with 15 genera and nearly 200 species, is recognized. That such a natural group may exist is quite likely, but about its composition and limits much doubt cannot fail to be entertained. If its existence be acknowledged, the remarkable genera *Orthotomus* with about 12 and *Cisticola* with some 30 species may be fairly admitted as belonging to it. The former includes the Tailor-birds of the Indian region of which all have heard or read, for their habit of sewing together the leaves of plants so as to form a cone in which to build their nests has often been described and the fabric figured. Jerdon (*B. India*, ii. p. 166) writes of the common Indian Tailor-bird, *O. longicauda*, that it "makes its nest of cotton, wool, and various other soft materials," and "draws together one leaf or more, generally two leaves, on each side of the nest, and stitches them together with cotton, either woven by itself, or cotton thread picked up; and, after passing the thread through the leaf, it makes a knot at the end to fix it." *Cisticola*, of which one species inhabits the south of Europe, follows the same trade on stems of grass, confining them by stitches above the nest, which assumes a globular form.

---

[1] For this reference, not before precisely given, the writer is indebted to the Rev. G. M'Arthur.

[2] These are exotic birds having no recognized English name. Those of "Babblers," "Bush-Babblers," and "Babbling-Thrushes" have been applied to them by some writers, who consider them to be sufficiently characterized by their short, rounded, and incurved wings.

[3] *Cf.* Mr. Sharpe's meritorious efforts, *Cat. B. Brit. Museum*, vols. vi. and vii.

In the same group *Drymœcinæ* is placed by some authors the Australian genus *Malurus*, to which belong the birds known as "Superb Warblers," and they are not inaptly so named, since in beauty they surpass any others of their presumed allies. Part of the plumage of the cocks in breeding-dress is generally some shade of intense blue, and is so glossy as to resemble enamel, while black, white, chestnut, or scarlet, as well as green and lilac, are also present in one species or another, so as to heighten the effect. But, as already stated, there are systematists who would raise this genus, which contains some 15 species, to the rank of a distinct Family, though on what grounds it is hard to say.

Of the other Subfamilies, *Saxicolinæ*, *Sylviinæ*, and *Phylloscopinæ*, will be conveniently treated under WHEATEAR. WHITETHROAT, and [Willow-] WREN (*qq.v.*), while the *Ruticillinæ* have been already mentioned under NIGHTINGALE, REDBREAST, and REDSTART, and the *Accentorinæ* under [Hedge-] SPARROW.

The birds known as "American Warblers," forming what has now for a long while been almost universally recognized as a distinct Family, *Mniotiltidæ*, remain for consideration. They possess but nine instead of ten primaries, and are peculiar to the New World. More than 130 species have been described, and these have been grouped in 20 genera or more, of which members of all but three are at least summer visitants to North America. As a whole they are much more brightly colored than the *Sylviidæ* (*Malurus*, if it belongs.to them, always excepted); for, though the particular genus *Mniotilta* (from which, as the fortune of nomenclature will have it, the Family takes its right name)[1] is one of the most abnormal—its colors being plain black and white, and its habits rather resembling those of a TREE-CREEPER (*q.v.*)—in other groups chestnut, bluish-gray, and green appear, the last varying from an olive to a saffron tint, and in some groups the yellow predominates to an extent that has gained for its wearers, belonging to the genus *Dendrœca*, the name of "Golden" Warblers. In the genus *Setophaga*, the members of which deserve to be called "Fly-catching" Warblers, the plumage of the males at least presents yellow, orange, scarlet, or crimson. Dr. Coues (*Key N.-Am. Birds*, ed. 2, p. 288), following on the whole the arrangement of Baird, Brewer, and Ridgway (*N.-Am. Birds*, i. p. 178), separates the whole Family (for which he arbitrarily retains the name *Sylvicolidæ* into three Subfamilies *Sylvicolinæ* (=*Mniotiltinæ*), *Icteriinæ*, and *Setophaginæ*, grouping the genera *Mniotilta*, *Parula*, and *Peucedromus* as "Creeping Warblers;" *Geothlypis*, *Oporornis*, and *Siurus* as "Ground-Warblers;" *Protomonotaria*, *Helminthotherus*, and *Helminthophilu* as "Worm-eating Warblers;" *Sstophaga*, *Cardellina*, and *Myiodioctes* as "Fly-catching Warblers;" *Icteria*, which perhaps may not belong to the Family, standing alone; and *Dendrœca* as "Wood-Warblers."

The *Mniotiltidæ* contains forms exhibiting quite as many diverse modes of life as do the *Sylviidæ*. Some are exclusively aquatic in their predilections, others affect dry soils, brushwood, forests, and so on. Almost all the genera are essentially migratory, but a large proportion of the species of *Dendrœca*, *Setophaga*, and especially *Basileuterus*, seem never to leave their Neotropical home; while the genera *Leucopeza*, *Teretristis*, and *Microligia*, comprising in all but 5 species, are peculiar to the Antilles. The rest are for the most part natives of North America, where a few attain a very high latitude,[2] penetrating in summer even beyond the Arctic Circle, and thence migrate southward at the end of summer or in the fall of the year, some reaching Peru and Brazil, but a few, as, for instance, *Parula pitiayumi* and *Geothlypis velata* seem to be resident in the country last named.

To return, in conclusion, to the *Sylviidæ*, or true Warblers, it is to be hoped that before long some competent ornithologist will take on himself the task, necessary if toilsome and perhaps ungrateful, of revising the work that has lately been done upon them and upon the *Turdidæ*, and, setting aside all preconceived notions except that of aiming at the truth, without prejudice fix the limits of the two Families, if Families they be, and at the same time adjust the relations of the hitherto very indefinite group *Timeliidæ*.

(A. N.)

WARBURTON, ELIOT BARTHOLOMEW GEORGE (1810–1852), traveller and novelist, born in 1810 near Tullamore, Ireland, made a hit with his first book, *The Crescent and the Cross*. It was a book of Eastern travel, in Turkey, Syria, Palestine, and Egypt, and fairly divided public attention with Mr. Kinglake's *Eothen*, which appeared in the same year, 1844. Interest was centred in the East at the time, and Warburton had popular sympathy with him in his eloquent advocacy of the annexation of Egypt; but, apart from this harmony with the tastes of the time, the traveller had so many adventures, told them with such spirit, described what he saw with such picturesque vigor, and sketched character with such animation and generosity, that the success of the book on its merits was perfectly legitimate. Warburton was an Irishman, with an Irishman's rhetoric and spirit of adventure, who, after an education at Cambridge, was called to the Irish bar, tried to settle down on his paternal estate, but very soon abandoned the management of his tenants for a life of nobler excitement. His first success as an author tempted him to try again, but he had unhappily a short career, and did not again equal *The Crescent and the Cross*. His most substantial work was a *Memoir of Prince Rupert*, published in 1849, enriched with original documents, and written with eloquent partiality for the subject. This was followed in 1850 by a novel, *Reginald Hastings*, the scenes of which were laid in the same period of civil war. It was much more commonplace than his travels, and showed no power of construction or felicity in the creation of character. He produced another historical novel, *Darien, or the Merchant Prince* (1851). The knowledge therein shown of the inhabitants of the isthmus led to his selection by the Atlantic and Pacific Company to explore the country and negotiate a treaty with the Indian tribes. He sailed on this mission in the "Amazon," which perished by fire with nearly all on board on the 4th of January, 1852.

His *Life of the Earl of Peterborough* was published posthumously in 1853. To the *Memoirs of Horace Walpole* (1851), nominally edited by him, he contributed, as he avowed in the preface, only his advice to the anonymous author and the countenance of his name.

WARBURTON, WILLIAM (1698–1779), bishop of Gloucester, was the son of the town clerk of Newark, where he was born on December 24, 1698. He was educated at Oakham and Newark grammar schools, but, being intended for his father's profession, does not seem to have addicted himself especially to the classics, or to have manifested extraordinary proficiency in any study. He lost his father while a boy, and in 1714 he was articled to Mr. Kirke, attorney at Great Markham, in Nottinghamshire, and after serving his time with him returned to Newark with the intention of practicing as a solicitor. Whether he ever did seems uncertain, but a very short time afterwards he is found studying Latin and Greek under the master of Newark school, who frequently sat up till late at night with his pupil. In 1723 he was ordained deacon by the archbishop of York, and on March 1, 1727, received priest's orders from the bishop of London. He had occupied the interval in various literary labors, the most important being the notes he contributed to Theobald's edition of Shakespeare, and an anonymous pamphlet on a question which had arisen concerning the jurisdiction of the Court of Chancery.

---

[1] By some writers the Family is called *Sylvicolidæ*, a practice which contravenes the ordinary usage of nomenclaturists, since the name *Sylvicola* in ornithology is preoccupied by its employment in conchology.

[2] Seven species have been recorded as wandering to Greenland, and one, *Dendrœa virens*, is said to have occurred in Europe (*Naumannia*, 1858, p. 425).

Warburton had undertaken to answer another anonymous pamphlet, which proved to be the composition of no less a person than Mr. Yorke, afterwards Lord Chancellor Hardwicke, and the impression which he made upon his antagonist was evinced by the pains the latter took with his reply. He now received from Sir Robert Sutter the small living of Griesley, in Nottinghamshire, exchanged next year for that of Brant Broughton, in Lincolnshire, and was made an honorary M.A. of Cambridge. Here for eighteen years he spent his time in intense study, the first result of which was his celebrated treatise on the alliance between church and state, published in 1736. The work was probably intended, and certainly admirably adapted, to afford the ministry of the day an excuse for omitting to redeem their promise to the Dissenters of freeing them from the bondage of the Test and Corporation Acts. To this end the test is represented as the only possible means of reconciling the principle of a religious establishment with that of a free toleration, a piece of logic which, now that religious tests are no longer held a qualification for civil office, would excite most opposition where it originally gained most favor. It fully answered its temporary purpose, and equally subserved the author's real end by gaining him credit at court. It would appear that he only missed immediate preferment by the death of Queen Caroline. His next performance, the famous *Divine Legation of Moses Demonstrated on the Principles of a Religious Deist*, the first part of which was published in 1738, will long preserve his name as the author of the most daring and ingenious of theological paradoxes. The deists had made the absence of any inculcation of the doctrine of a future life an objection to the divine authority of the Mosaic writings. Warburton boldly admits the fact and turns it against the adversary. No human legislator. he contends, would have omitted such a sanction of morality; *ergo*, the legislation was divine. It may be doubted whether the argument ever convinced any one; and its cogency was not assisted by the multitude of minor paradoxes with which it was interwoven, such as the identification of the scenery of the sixth book of the *Æneid* with the exhibitions of the Eleusinian mysteries. But the author's extraordinary power, learning, and originality were acknowledged on all hands, though he excited censure and suspicion by a circumstance highly honorable to him, his tenderness to the alleged heresies of Conyers Middleton. The second volume of the work appeared in 1741.

Warburton's next undertaking, though still theological, brought him into the field of general literature. Either in quest of another paradox, or actually unable to recognize the Spinozistic tendency of Pope's *Essay on Man*, he entered upon its defence against Crousaz, in a series of articles contributed to *The Republic of Letters*. Whether Pope had really understood the tendency of his own work has always been a question. but there is no question that he was glad of an apologist, or that Warburton's *jeu d'esprit* (for him it was hardly more) in the long run did more for his fortunes than all his erudition. It occasioned a sincere friendship between him and Pope, whom he persuaded to add a fourth book to the *Dunciad*, and substitute Cibber for Theobald as the hero of the poem. Pope bequeathed him the copyright and the editorship of his works, and contributed even more to his advancement by introducing him to Murray, afterwards Lord Mansfield, who obtained for him the preachership of Lincoln's Inn, and to Ralph Allen, who, says Johnson, "gave him his niece and his estate, and, by consequence, a bishopric." The marriage took place in 1745. and from that time Warburton resided principally at his father-in-law's estate at Prior Park, in Gloucestershire, which he inherited on Allen's death in 1764. In 1747 appeared his edition of Shakespeare, into which, as he expressed it, Pope's previous edition was melted down. He had previously entrusted notes and emendations on Shakespeare to Sir Thomas Hanmer, whose unauthorized use of them led to a warm controversy. Warburton was further kept busy by the attacks on his *Divine Legation* from all quarters, by a dispute with Bolingbroke respecting Pope's behavior in the affair of Bolingbroke's *Patriot King*, and (1750) by a work of more importance in vindication of the alleged miraculous interruption of the rebuilding of the temple of Jerusalem undertaken by Julian. Here again Warburton shows his habitual intrepidity as a controversialist, and places himself upon ground where few at the present day would care to follow him. His defence of revelation was continued in his *View of Bolingbroke's Posthumous Writings* (1754), universally allowed to be a most masterly performance. Warburton's manner of dealing with opponents would be in our day considered both insolent and rancorous, but it did him no disservice in his own. In 1757 he was made dean of Bristol, and in 1760 bishop of Gloucester.

Mr. Abbey characterizes Warburton as an inactive bishop, and the partial Hurd can say no more than that "he performed the duties of his office with regularity, but further than this he could not prevail with himself to go." Nor did he ever seek to shine in parliament. He continued, however, active with his pen, so long as the infirmities of age allowed, collecting and publishing his sermons, reprinting his principal works with large additions, toiling to complete the *Divine Legation*, the last book of which appeared after his death, and writing (1762) a vigorous attack on Methodism under the title of *The Doctrine of Grace*. Of this work his friend and biographer Hurd says, with curious infelicity, "the sect will find a sort of immortality in this discourse." The reverse has proved true, yet the book ranks among the author's most powerful productions. He also engaged in a keen controversy with Bishop Lowth on the book of Job, which even his admiring biographer wishes forgotten. His last important act was to found, in 1768, the Warburtonian lecture, "to prove the truth of revealed religion from the completion of the prophecies in the Old and New Testament which relate to the Christian church, especially to the apostacy of Papal Rome." "On the right determination of the prophecies relating to Antichrist," he said, "one might rest the whole truth of the Christian religion," another opinion which finds little support in the 19th century. The principal authority for his latter years is his correspondence with his friend Bishop Hurd, an important contribution to the literary history of the period. After the death of his only son in 1776 he fell into a lethargic languor, which was terminated by death on June 7, 1779.

Warburton was undoubtedly a great man, but his intellect, marred by wilfulness and the passion for paradox, has effected no result in any degree adequate to its power. He disdained to persuade unless he could at the same time astonish, and in endeavoring to amaze he has failed to convince. None of the propositions with which his name is chiefly connected have found acceptance with posterity, and while abundantly demonstrating his own learning he has failed to make any considerable addition to the stock of human knowledge, or to leave any signal mark on the history of opinion. He was rather a gladiator than a warrior, an exhibitor of brilliant fence leading to no definite end. Though always faithful to his convictions, he argued for victory rather than truth, and wasted upon advocacy powers which would have produced great results if they had been employed in serious and dispassionate investigation. His rude and arrogant style of controversy deserved and received severe reprehension; it was at all events free from pettiness and malignity; and his faults were in general those of an aspiring and magnanimous nature. He was a warm and constant friend, and gave many proofs of gratitude to his benefactors. As an editor and critic he displayed much force of mind, but his standard of research was not high, and his literary taste was that of the 18th century. (R. G.)

WARD. See INFANT.

WARD, EDWARD MATTHEW (1816–1879), history and *genre* painter, was born at Pimlico, London, in

1816. Among his early boyish efforts in art was a series of clever illustrations to the *Rejected Addresses* of his uncles Horace and James Smith, which was followed soon afterwards by designs to some of the papers of Washington Irving. In 1830 he gained the silver palette of the Society of Arts; and in 1835, aided by Wilkie and Chantrey, he entered the schools of the Royal Academy, having in the previous year contributed to its exhibition his portrait of Mr. O. Smith, the comedian, in his character of Don Quixote. In 1836 he went to Rome, where in 1838 he gained a silver medal from the Academy of St. Luke for his Cimabue and Giotto, which in the following year was exhibited at the Royal Academy. The young artist now turned his thoughts to fresco-painting, which he studied under Cornelius at Munich. In 1843 he forwarded his Boadicea Animating the Britons previous to the Last Battle against the Romans to the competition for the decoration of the Houses of Parliament,—a work upon which he was afterwards engaged, having in 1853 been directed by the fine art commissioners to execute eight subjects in the corridor of the House of Commons. The success of his Dr. Johnson in Lord Chesterfield's Ante-Room—now in the National Gallery, along with the Disgrace of Lord Clarendon (the smaller picture) (1846), the South Sea Bubble (1847), and James II. receiving the News of the Landing of the Prince of Orange (1850)—secured his election as an associate of the Royal Academy in 1847, and in 1855 he gained full academic honors. Among the more important of his other works may be named Charlotte Corday Led to Execution (1852), the Last Sleep of Argyll (1854), the Emperor of the French Receiving the Order of the Garter (1859), painted for the queen, the Ante-chamber at Whitehall during the Dying Moments of Charles II. (1861), Dr. Johnson's First Interview with John Wilkes (1865), and the Royal Family of France in the Temple, painted in 1851, and usually considered the artist's masterpiece. For several years before his death Ward suffered from ill-health and mental depression, which led to temporary aberration of intellect. He died at Windsor, on January 15, 1879.

Ward's pictures have been extremely popular, and the engravings which reproduce so many of them have had a wide circulation. His works are generally interesting in subject; they tell their story with point and clearness, are correct and learned in costume, and full of observation and character. In purely technical qualities, in lighting, tone, color, and draughtsmanship, they are more frequently open to exception.

WARD, JAMES (1769–1859), animal painter and engraver, was born in Thames Street, London, on October 23, 1769. At the age of twelve he was bound apprentice with J. Raphael Smith, but he received little attention and learnt nothing from this engraver. He was afterwards instructed for over seven years by his elder brother, William Ward, and he engraved many admirable plates, among which his Mrs. Billington, after Reynolds, occupies a very high place. He presented a complete set of his engravings, in their various states, numbering three hundred impressions, to the British Museum. While still a youth he made the acquaintance of George Morland, who afterwards married his sister; and the example of this artist's works induced him to attempt painting. His early productions were rustic subjects in the manner of Morland, which were frequently sold as the work of the more celebrated painter. His Bull-Bait, an animated composition, introducing many figures, attracted much attention in the Royal Academy of 1797. A commission from Sir John Sinclair, president of the new agricultural society, to paint an Alderney cow led to much similar work, and turned Ward's attention to animal-painting, a department in which he achieved his highest artistic successes, his renderings of cattle being unrivalled in the English school, and worthy to rank with the pictures of the great animal-painters of Holland. His Landscape with Cattle, acquired for the National Gallery at a cost of £1500 ($7290) was painted in 1820–22 at the suggestion of West, in emulation of the Bull of Paul Potter at The Hague. His Boa Serpent Seizing a Horse was executed in 1822, and his admirable Gray Horse, shown in the Old Masters' Exhibition of 1879, dates from 1828. Ward also produced portraits, and many landscapes like the Gordale Scar and the Harlech Castle in the National Gallery. Sometimes he turned aside into the less fruitful paths of allegory, as in his unsuccessful Pool of Bethesda (1818), and Triumph of the Duke of Wellington (1818). He was a frequent contributor to the Royal Academy and the British Institution, and in 1841 he collected one hundred and forty examples of his art, and exhibited them in his house in Newman Street. He was elected an Associate of the Royal Academy in 1807, and a full member in 1811, and died at Cheshunt on the 23d of November, 1859.

Ward compiled an autobiography, of which an abstract was published in the *Art Journal* in 1849.

WARD, WILLIAM (1766–1826), mezzotint-engraver, an elder brother of James Ward (see above), was born in London in 1766. He was the most distinguished pupil of J. Raphael Smith, and executed a great part of many of the plates which bear the name of that excellent engraver. In 1795 he began to exhibit in the Royal Academy, of which in 1814 he was elected an associate engraver. He also held the appointment of mezzotint-engraver to the prince regent and the duke of York. He executed six plates after Reynolds, engraved many of the works of his brother-in-law, George Morland, and his mezzotints after Andrew Geddes, which include the full lengths of Sir David Wilkie and of Patrick Brydone, are of great merit. His engravings are full of artistic spirit, and show fine feeling for color; and they are excellently tender and expressive in their rendering of flesh. He died suddenly at Mornington Place, on December 1, 1826.

WARDHÁ, or **WURDA**, a British district in the chief commissionership of the Central Provinces of India, with an area of 2401 square miles. It lies between 20° 18′ and 21° 21′ N. lat. and 78° 4′ 30″ and 79° 15′ E. long., and forms a triangle with its apex towards the northwest, the base resting on Chanda district; on the east it is bounded by Nágpur, and on the west the Wardhá river separates it from Berar. Wardhá is hilly in the north, and intersected by spurs from the Satpura range. The central portion includes the three peaks of Málegáon (1726 feet), Nándgáon (1874 feet), and Jaitgarh (2086 feet). From this cluster of hills numerous small streams lead to the Wardhá river on the one side, while on the other the Dham Bor, and Asodá *nálá* flow down the length of the district in a southeasterly direction. The Wardhá, and its affluent the Waná, are the only rivers of any importance. To the south the country spreads out in an undulating plain, intersected by watercourses, and broken here and there by isolated hills rising abruptly from the surface. In general the lowlands are well wooded. Leopards, hyænas, wolves, jackals, and wild hogs abound in the district; other animals found are the spotted deer, *nilgai*, wild goat, and antelopes. Among birds are the bustard, partridge, quail, and rock pigeon. There are numerous roads and 65 miles of railway. The district is subject to great variations of climate, and the rainfall at Wardhá town averages nearly 40 inches.

The census of 1881 disclosed a population of 387,221 (males 195,564, females 191,657), Hindus numbering 328,523, Mohammedans 14,200, Christians 96, and aboriginals 41,933. The district contains five towns with a population exceeding 5000. Wardhá (5816), the chief town, has wide and regular streets, having been built in 1866. Of the total area 1500 square miles are cultivated; while of the portion lying waste 380 square miles are returned as cultivable. The chief crops are cotton, wheat, other food-grains, and oil-seeds. The only manufacture of any importance is cotton cloth, the greater part of which is exported to Berar and to the districts farther west. Cotton thread, blankets, gunny, and rope are also made, and since the completion of the railway a considerable trade has also sprung up in butter, which finds a ready sale in the Bombay market. But by far the most important article exported is the raw cotton known as "Hingaughâts," from the cotton mart of that name. The principal imports are salt, English piece goods, hardware, and spices. In 1886–87 the gross revenue of the district amounted to £99,955 [$485,781.30], of which the land yielded £51,494 [$250,260.84]. The history of Wardhá forms part of that of Nágpur district, from which it was separated in 1862 for administrative purposes.

WARE, an ancient market-town of Herts, England, is situated in a valley on the north side of the river Lea, and on a branch of the Great Eastern railway, 2 miles east-northeast of Hertford, and 22¼ north of London by rail. The principal street is the spacious High Street, running east and west by the river. The houses are chiefly modern, but there are a few of the old timber frame-houses. The Lea, by means of which there is good water communication, is crossed by an iron bridge erected in 1845. The New River Head is half a mile distant. The parish church of St. Mary is a large and handsome cruciform building of flint and stone in the Perpendicular style, consisting of chancel (built, it is supposed by Lady Margaret Beaufort, countess of Richmond, and mother of Henry VII.), lady chapel to the south (about 1380), nave of five bays of the time of Richard II., transepts, aisles, south porch, and embattled tower of the time of Edward III. There is an elaborate font of the time of Henry IV., and a few old brasses and monuments. The church has undergone restoration in 1848, 1881, and 1885–86. The modern mansion of the Priory, to the west of the town, occupies the site of a priory of the order of St. Francis, founded by Margaret, countess of Leicester, sister of Henry III., who was then lady of the manor of Ware. A considerable portion of the original building is incorporated in the modern one. Among the modern public buildings are the corn exchange and the town-hall, which includes a literary institute and library. There is a recreation ground 6 acres in extent, and a cemetery of 4 acres. The famous "great bed of Ware" referred to in Shakespeare's *Twelfth Night*, which formerly was at the Saracen's Head, has been removed to Rye House, 2 miles distant. The town possesses breweries and brick-fields, and there is a large trade in malt. The population of the urban sanitary district (area about 641 acres) in 1871 was 4917, and in 1881 it was 5277.

Roman remains have been discovered at various times in the neighborhood of Ware, and the Ermine Street crossed the Lea valley just a little above it. At the time of the Domesday survey the town had 130 inhabitants, and belonged to Hugh de Grentemaisnil. In the reign of John it came into the possession of Saier de Quincy, earl of Winchester, who, by forcing the thoroughfare of the bridge by breaking the chain, and thus freeing the bridge of toll, greatly increased the trade of the town. The tolls, were however, again imposed. They were granted by Charles I. to William, earl of Salisbury, and they are still collected from non-resident traders. Robert de Quincy in 1254 received for the town the grant of a market and fair from Henry III. In the 15th century it came into the possession of the earl of Warwick, the king-maker. On the death of Richard, duke of Gloucester, it was settled by Henry VII. on his mother, the countess of Richmond. It was then granted to Margaret Plantagenet, countess of Salisbury, on whose execution in 1541 it reverted to the crown. Queen Mary on her accession restored it to Catherine, countess of Huntingdon, granddaughter of the countess of Salisbury, who about 1570 sold it to Thomas Fanshawe, remembrancer in the exchequer. About 1700 the manor was sold to Sir Thomas Byde, a London brewer, in whose family it remained till 1846. Ware is the "town of fame" alluded to by Cowper in his "John Gilpin." William Godwin was for some time minister of the Independent chapel there. William of Ware was the teacher of Duns Scotus.

WARMINSTER, an ancient market-town of Wiltshire, England, is situated on elevated ground, at the western extremity of Salisbury Plain, near the Somerset border, on the river Wily, and on a branch of the Great Western Railway, 17 miles southwest of Devizes, 21 northwest of Salisbury and 105 south-southwest of London by rail. It consists chiefly of one street about a mile in length. The parish church of St. Denys is an ancient stone structure of various styles, the south porch and tower being of the time of Edward III., the chancel Perpendicular, and the nave of the 18th century. It is now (1888) undergoing complete restoration at a cost of £9000 [$43,140], the nave being in process of entire reconstruction. The town-hall was erected by the marquis of Bath in 1830. Among the benevolent institutions are the free school, established in 1707 by the first Viscount Weymouth, the missionary college of St. Boniface (1860), the community of St. Denys home (1866) for training young women to assist in missionary work, the Wilts reformatory for boys (1856), the cottage hospital (1866), the almshouses for four aged women (1873), and an orphanage. The town possesses a large silk mill, engineering and agricultural implement works, and malt-works. There is a considerable agricultural trade. The population of the urban sanitary district (area 6370 acres) in 1871 was 5786, and in 1881 it was 5640.

Warminster is probably of ancient British origin, and the neighborhood is remarkable for the number of its barrows. The old Roman road from Old Sarum to Bath skirted Warminster to the north. Camden supposes it to have been the Roman *Verlucio*, and, although this conjecture is probably wrong, there can be no doubt that it was a Roman station of importance. The barrows within the entrenchments at Battlesbury camp, a little to the east, indicate an earlier than Roman occupation, but the entrenchments were probably themselves the work of the Romans. A great variety of Roman remains have been found in the neighborhood of the town. Warminster was a royal manor in the time of Edward the Confessor, and as such was free of taxes and assessments. In Domesday the name occurs as Guerminster. It then possessed 30 burgesses and probably a total population of over 400. It was bound to provide a night's lodging for the king and all his retinue. Its early importance was chiefly owing to its situation at the junction of the roads from Bath, Frome, Salisbury, and Shaftesbury. It remained a royal manor till the reign of Henry II.

WARRANT, in law, is an authority empowering a person to act in a way which would not be lawful without such authority. The term occurs very early in constitutional documents: it is found in the Assize of Clarendon and the Assize of the Forest, both in the reign of Henry II. A warrant must be under the hand and seal of the person issuing it, unless such formalities be dispensed with by statute. Warrants are of several kinds, and may be conveniently divided into four classes, which may be called the executive, the judicial, the financial, and the private.

Executive.—A warrant under the sign-manual of the king, countersigned by the lord chancellor or a secretary of state, is still in use for some purposes. It is the means of granting PARDON (*q.v.*) and letters patent (except those for inventions), and of framing certain regulations for the forces. It was by royal warrant (afterwards confirmed by Act of Parliament) that purchase of commissions in the army was abolished in 1871.[1] By 18 Hen. VI., c. 1, letters patent are to bear the date of the king's warrant delivered to the lord chancellor. The issue of warrants under the sign-manual has been recently regulated by the Great Seal Act, 1884. Such a warrant must bear a ten-shilling stamp. Royal warrants were at one time in considerably more frequent use than they are at present. For instance, in 1602 the censorship of the stage was committed to the poet Daniel by royal warrant (see THEATRE). A false representation that any goods were made by a person holding a royal warrant is now punishable under the Merchandise Marks Act, 1887. The issue of warrants under the hand of a secretary of state is now, with two exceptions, confined to cases in which there is suspicion of treason or treasonable practices, and the warrant must name the person whom it is intended to arrest. The exceptions are the cases of bringing up a prisoner to give evidence under 16 and 17 Vict. c. 30, and warrants issued under the Extradition Act (see EXTRADITION). By 16 Car. I. c. 10, if any person be imprisoned by warrant of the king in person, of the council board, or any of the privy council, he is entitled to a writ of *habeas corpus*. By the Habeas Corpus Act. 31 Car. II. c. 2, detention on a legal warrant is good ground for refusing discharge to the prisoner on return to a writ of *habeas corpus*. General warrants of a secretary of state were decided to be illegal in 1763. A named person may still be committed by a secretary of state's warrant, but his papers cannot be seized (see PRESS LAWS). Power to issue warrants to search for arms and to arrest for treason or treasonable practices in Ireland has been given by various Acts, *e.g.*, 44 Vict. cc. 4, 5, and by the Criminal Law and Procedure Act, 1887. The right of a secretary of state or the lord lieutenant in Ireland by a warrant to detain or open letters in the post-office still exists, and has been recognized by orders in council and proclamations in the 17th century, and more recently by various Post-Office Acts, such as 9 Anne c. 10, 35 Geo. III. c. 62, 7 Will. IV. and 1 Vict. c. 36. The right was finally established by the reports of committees of both houses appointed in 1844 on a complaint by Mazzini and others that Sir James Graham, then home secretary, had opened their letters. It was exercised as recently as 1881 over the letters of persons suspected of treasonable correspondence in Ireland. Committal for breach of privilege of the House of Commons is by warrant of the speaker. A warrant of a law officer of the crown for sealing letters patent for invention was necessary under the old patent law, but has been superseded by other procedure since the Patents Act, 1883. The lowest form of executive warrant is the warrant of a sheriff to his bailiff in pursuance of a writ.

---

[1] The warrant officer (so called no doubt from the mode of his appointment) is a distinct rank in both the army and navy. For the warrant officer in the navy, see vol. xvii. p. 301–2.

Judicial.—Warrants of this kind are used in either civil or criminal procedure. The only kind used in both seems to be that issued by a judge of the High Court, who has the same jurisdiction as a secretary of state under 16 and 17 Vict. c. 30. In civil procedure the warrant in a county court corresponds very nearly to the WRIT (*q.v.*) in the High Court. Examples of county court warrants are those of attachment, delivery, execution, and possession. The warrant of arrest in Admiralty is a form of procedure confined to Courts of Admiralty jurisdiction. The most important and frequent use of the warrant is for the apprehension of an accused person to be brought before a court of summary jurisdiction, either in the first instance, or on failure to obey a summons (see SUMMARY JURISDICTION, SUMMONS): such warrants are usually issued by a justice of the peace; when issued by the court they are called bench warrants. Where issued by a justice for execution out of his jurisdiction, a warrant must usually be backed by another justice having jurisdiction where it is to be executed. The warrant of a justice may also issue in some non-judicial matters, *e.g.*, for the compulsory supply of carriages under the Army Act, 1881. There are certain warrants which by common law or statute extend much further than ordinary judicial warrants. Those issued under the Fugitive Offenders Act, 1881, if duly backed, extend throughout the British empire. Warrants of a court having jurisdiction in bankruptcy run throughout the United Kingdom. A judge of the Queen's Bench Division has, both at common law and by statute, authority to issue a warrant in certain cases. Such a warrant is valid throughout England. Execution of the decisions of a court of summary jurisdiction is secured by warrants, part of the process of the court, such as warrants of distress or commitment. A warrant may also issue for the apprehension of a witness whose attendance cannot be otherwise assured. A search warrant may be granted for the purpose of searching suspected premises for stolen goods. Special powers for issuing such warrants are given by the Army, Merchant Shipping, Customs, Pawnbrokers, Stamp, and other Acts. The Criminal Law Amendment Act, 1885, allows the issue of search warrants where it is suspected that a female is unlawfully detained for immoral purposes. As a general rule no one can be arrested without warrant. To this rule there are certain exceptions either at common law or by statute. At common law a justice of the peace, a sheriff, a coroner, a constable, and even a private person, may arrest any one without warrant for a treason, felony, or breach of the peace committed, or attempted to be committed, in his presence. A constable (whether a constable at common law or a police constable appointed under the Police Acts) may arrest a person indicted for felony; a constable or a private person may arrest on reasonable suspicion that he who is arrested has committed a felony. But in the latter case he does so at his peril, for he must prove (what the constable need not) that there has been an actual commission of the crime by some one, as well as a reasonable ground for suspecting the particular person. What is a reasonable ground it is of course impossible to define, but, in the case of a constable, a charge by a person not manifestly unworthy of credit is generally regarded as sufficient. An accused person who has been bailed may be arrested by his bail, and the police may assist in the arrest. In neither case is a warrant necessary. Nor is it necessary for the apprehension of one against whom the hue and cry is raised (see THEFT). The king cannot arrest in person or by verbal command, as no action would lie against him for wrongful arrest. Statutory powers of arrest without warrant are given to both constables and private persons by numerous Acts of Parliament, for instance, the Game Act of 9 Geo. IV. c. 69, various Police Acts, the Criminal Law Consolidation Acts of 1861, the Prevention of Crime Act, 1871. The possession of a legal warrant by a peace officer on arrest is of great importance in determining whether the person resisting apprehension is justified or not in so doing. Should the officer attempt to apprehend him on an illegal warrant, or without a warrant in a case where a warrant is necessary, and be killed in the attempt, the killing would probably be held to be manslaughter and not murder. The authorities on this point are, however, conflicting. In an action against a peace officer for arrest on an illegal warrant, he is, by 24 Geo. II. c. 44, entitled to demand perusal and a copy of the warrant. Execution of warrants in border counties of England and Scotland, and backing and execution of warrants issued in one part of the kingdom by justices and officers of another part, are specially provided for by numerous Acts of Parliament. Forms of warrants will be found in the schedule to the rules under the Summary Jurisdiction Act and the appendix to the County Court Rules, 1886.

Financial.—Payment out of the treasury is generally made upon warrant. Treasury warrants are regulated by many of the Acts dealing with the national debt. Payment of dividends by trading corporations and companies is generally made by means of dividend warrants.

Private.—Warrants issued by private persons are either mercantile or non-mercantile. Mercantile warrants are negotiable instruments giving a right to the delivery of goods, generally those deposited at a dock or warehouse, and by mercantile custom regarded as documents of title to the goods to which they relate. They have been recognized by the legislature, especially in the Factors Acts (see FACTOR). Thus the interpretation clause of one of those Acts, 5 and 6 Vict. c. 39, included under the head of documents of title India warrants, dock warrants, and warehouse keepers' warrants. The forgery of any warrant or endorsement or assignment of any warrant of this kind is by

24 and 25 Vict. c. 98 punishable with a maximum penalty of penal servitude for life. The stamp on such a warrant is, with certain exceptions, threepence. Among private warrants of a non-mercantile kind those in the most frequent use are warrants of distress, by which a landlord empowers his agent to distrain for arrears of rent.

Warrant of Attorney to confess judgment is a security for money (now practically obsolete) in the form of a warrant to a solicitor named by the creditor, empowering him to sign judgment in an action against the debtor for the sum due, with a defeasance, or clause that the warrant shall not be put into force in case of due payment of the money secured. It was often used as a collateral security for the payment of an annuity. The Debtors Act, 1869, contained various provisions for making known to the debtor the extent of the liability incurred by him, among others that the warrant must be executed in the presence of a solicitor named by the debtor, and that it and the defeasance must be written on the same paper. A warrant of attorney must be duly stamped, generally as a MORTGAGE (*q.v.*), and must be registered as a judgment in the central office of the Supreme Court.

QUO WARRANTO (*q.v.*) is a means of determining the right of a person to continue to hold an office.

Scotland.—By Art. xxiv. of the Articles of Union royal warrants were to continue to be kept as before the union. The Secretary for Scotland Act, 1885, enabled the crown by royal warrant to appoint the secretary to be vice-president of the Scotch Education Department. The lord advocate's warrant runs throughout the whole of Scotland. Warrants issued by courts of summary jurisdiction agree in the main with those in use in England, though their names are not the same (see SUMMARY JURISDICTION). There are numerous statutory provisions as to warrants of other kinds. By 1 and 2 Vict. c. 114 warrants for diligence, and to charge the debtor under pain of imprisonment, may be inserted in an extract of decree; and in a summons concluding for payment of money a warrant to arrest the movables, debts, and money of the defender may be included. By 31 and 32 Vict. c. 100 a warrant of inhibition may be inserted in the will of a summons. A crown writ is a warrant for infeftment (31 and 32 Vict. c. 101). The same Act gives forms of warrants of REGISTRATION (*q.v.*). The practice as to warrants of citation and commitment in the High Court of Justiciary and the sheriff court now depends chiefly on the Criminal Procedure Act, 1887, 50 and 51 Vict. c. 35. The *meditatio fugæ* warrant is a judicial warrant on which imprisonment may follow until the debtor give *cautio judicio sisti.* It corresponds to some extent to the writ *ne exeat regno* of English practice, but it may be issued by a sheriff (1 and 2 Vict. c. 119). A border warrant for arresting a debtor on the English side of the border is another kind of judicial warrant. The warrant of attorney is not known in Scotland, its place being taken by the clause of registration, which has this advantage over the warrant of attorney that it is not avoided, as is the warrant, by the death of the person giving it.

United States.—By the constitutions of the United States and of almost all the States. warrants are not to issue but upon probable cause, supported by oath or affirmation, and particularly describing the place to be searched and the persons or thing to be seized. These provisions have been held not to mean that there shall be no arrest without warrant, but to confine the right of arrest to circumstances similar to those which justify it in English law. The constitutions of some States forbid general warrants. A warrant is generally necessary for the payment of money out of the United States or a State treasury.[1] (J. W†.)

WARRANTY is etymologically another form of GUARANTEE (*q.v.*). It is used, however, in a rather different sense. The sense common to both words is that of a collateral contract, under which responsibility for an act is incurred, and for the breach of which an action for damages lies. Warranty generally expresses the responsibility of the person doing the act, guarantee the responsibility of some other person on his behalf. A warranty may be defined, in the words of Lord Abinger, as "an express or implied statement of something which the party undertakes shall be part of the contract, and, though part of the contract, collateral to the express object of it" (Chanter *v.* Hopkins, 4 *Meeson and Welsby's Reports*, 404). It differs from a condition in that a condition forms the basis of the contract and a breach of it discharges from the contract, and from a representation in that the latter does not affect the contract unless made a part of it expressly or by implication, as in contracts of insurance and other contracts *uberrimæ fidei*, or unless it be fraudulent. These distinctions are not always accurately maintained. Thus in 8 and 9 Vict. c. 106, § 4, condition seems to be used for warranty.

Warranty as it affected the law of real estate was, up to half a century ago, a matter of the highest importance. A warranty in a conveyance was a covenant real annexed to an estate of freehold, and either expressed in a clause of warranty or implied in cases where a feudal relation might exist between feoffor and feoffee. The warranty, as described by Littleton, § 697, was an outgrowth of feudalism, and something very like it is to be found in the *Liber Feudorum.* At the time of Glanvill the heir was bound to warrant the reasonable donations of his ancestor. Warranty was one of the elements in Bracton's definition of homage, 78*b*, "juris vinculum quo quis astringitur ad warrantizandum defendendum et acquietandum tenentem suum in seisina versus omnes." For an express warranty the word *warrantizo* or warrant was necessary. The word "give" implied a warranty, as did an exchange and certain kinds of partition. In order to bind heirs a clause of warranty was required. This was either lineal, collateral, or commencing by disseisin. The differences between the three kinds were very technical, and depended on abstruse and obsolete learning. They are treated at great length in old works on real property, especially Coke upon Littleton by Butler, 364*b*. The feoffor or his heirs were bound by voucher to warranty or judgment in a writ of *warrantia chartæ* to yield other lands to the feoffee in case of the eviction of the latter. Vouching to warranty was a part of the old fictitious proceedings in a common recovery in use for the purpose of barring an entail before the Fines and Recoveries Act (see ENTAIL). Warranty of this nature, as far as it relates to the conveyance of real estate, though not actually abolished in all possible cases, is now superseded by covenants for title. The more usual of these are now by the Conveyancing Act, 1881, deemed to be implied in conveyances (see REAL ESTATE). For the implied warranties of title and quality see SALE. Vouching to warranty was at one time important in the law of personalty as well as of realty. The procedure is fully described in Glanvill. The right of calling on the holder of lost or stolen goods to vouch to warranty (*interciare*), *i.e.*, to give up the name of the person from whom he received them, under pain of forfeiture, was often granted under the name of *theam* as a local franchise (see THEFT). Warranty, as it exists at present in the law of personalty, is either express or implied. There is no general rule as to what constitutes a warranty. It is not necessary that an express warranty should be in writing, the law being that every affirmation at the time of sale of personal chattels is a warranty, provided that it appears to have been so intended. The principal cases of implied warranty occur in the contracts of sale and INSURANCE (*q.v.*). There is also an implied warranty in other kinds of contract, *e.g.*, of seaworthiness by the shipowner in a contract between him and a charterer for the hire of a ship. In all cases of implied warranty the warranty may be excluded by the special terms of the contract. For breach of warranty an action may be brought directly, or the breach may be used as ground for a counter claim or for reduction of damages, but the breach will not in the case of a warranty proper entitle the person suffering by it to a rescission of the contract. Thus in a sale the property passes although the warranty be broken. In some cases warranties on sale are the subject of statutory enactments. By the Merchandise Marks Act, 1887, a vendor is deemed to warrant that the trade mark or trade description on any goods sold is genuine. The Chain Cables and Anchors Act, 1874, enacts that every contract for the sale of a chain cable shall (in the absence of any stipulation to the contrary) imply a warranty that the cable has been duly tested and stamped. In some other Acts, such as the Bills of Exchange Act, 1882, the term warranty does not occur, but the practical effect is the same.

Scotland.—The term corresponding to warranty in the law of heritable property is "warrandice." Warranty, strictly speaking, seems confined to movables. Warrandice appears early in Scots law, the heir by *Regiam Majestatem* being bound to warrant the reasonable donations of his ancestor. Warrandice in the existing law is either real or personal. Real warrandice is that whereby warrandice lands are made over, as indemnity for those conveyed, to assure the person to whom they were conveyed from loss by the appearance of a superior title. Real warrandice is implied in excambion. Its effect is that the excamber, in case of eviction, may recover possession of his original lands. This is not in accordance with the English law in exchange. Personal warrandice is either express or implied. There is an implied warrandice in every onerous deed, and an absolute warrandice presumes an onerous consideration. Express warrandice is either simple, against the future acts of the vendor, from fact and deed, against acts whether past or future, or absolute, or against all deadly, that is, on any ground existing before the sale. A clause of warrandice is the Scottish equivalent of the English covenants for title. By 32 and 33 Vict. c. 116 a clause of warrandice in the form given in the schedule to the Act imports absolute warrandice as regards the lands and the title-deeds thereof, and warrandice from fact and deed as regards the rents. For the warranty in the sale of movables see SALE.

---

[1] [United States funds are received and disbursed on warrants or orders from the Secretary of the Treasury, certified by the register and countersigned by the first comptroller.—AM. ED.]

United States.—Warranty in conveyances of real estate is expressly abolished by statute in many States. In some States warranty is implied on the transfer and indorsement of negotiable instruments. (J. W†.)

WARREN, SAMUEL (1807–1877) author of *Ten Thousand a Year*, was born in Denbighshire in 1807. After a curriculum at the university of Edinburgh, of such distinction that he made the acquaintance of "Christopher North" through his undergraduate fame, he began the study of medicine, but soon abandoned it for the English bar. He entered at the Inner Temple in 1828, and was successful in his profession. He took silk in 1851, was made recorder of Hull, in 1854, represented Medhurst in parliament for three years (1856–59), and was rewarded by his party leaders in 1859 with a mastership in lunacy. Meantime he had made a much more brilliant success in fiction-writing. Very early in his career, before he was called to the bar, he had begun to write for *Blackwood*. His *Passages from the Diary of a Late Physician* appeared in that magazine between August, 1830, and October, 1831, being collected into two volumes in 1832. A third volume was published in 1838, the contents of which appeared originally in the same magazine between September, 1832 and August, 1837. These short stories, most of them of a horrible character, with morbid interest shielded under a moral purpose, were extremely popular, and so realistic that as long as the writer remained anonymous it was customary for doctors to declare that some brother must be making capital of the secrets of his profession. Warren's brief experience as a medical student thus stood him in good stead. But his great success was *Ten Thousand a Year*, which ran in *Blackwood* from October, 1839 to August, 1841, and was published separately immediately on its conclusion. Critics complained of the coarseness of the workmanship, of the banality of the moralizing, the crudeness of the pathos, the farcical extravagance of the humor; but meantime the work established itself as one of the most popular novels of the century. Of the higher qualities of imagination and passion Warren was destitute, but his sketches of character, especially farcical character, —Tittlebat Titmouse, Oily Gammon, Mr. Quicksilver (an open caricature of Lord Brougham),—are bold and strong, forcibly imprinted on the memory, and the interest of the story is made to run with a powerful current. For several years Warren was content to be known as the author of *Ten Thousand a Year*, and many tales were told of his open pride in the achievement. In 1847 he made another venture, but *Now and Then* was not a success. *The Lily and the Bee*, a squib on the Crystal Palace, published in 1851, though it had the honor of translation into Italian, was a signal failure. A pessimistic dissertation on *The Intellectual and Moral Development of the Age*, published in 1853, also fell flat, and thenceforth Warren, after publishing his *Works, Critical and Imaginative*, in four volumes in 1854, retired on his laurels. He died at London, July 29, 1877.

Besides his novels and other contributions to *Blackwood*, Warren wrote several legal works of repute—*Introduction to Law Studies* (1835), *Extracts from Blackstone* (1837), *Manual of Parliamentary Law* (1852).

His whole attitude towards the subject of insanity in its legal relations was determined by his clear perception and tenacious grasp of the fact that the disease insanity is merely one of the indicia of legal "unsoundness of mind;" he thus reduced medical expertism to its proper proportions, by treating the alienist as a witness and not a judge. The masterly brevity with which he addressed the jury in the Windham inquiry branded as practically irrelevant the mass of the evidence produced at the trial, and prepared the public mind for the third section of the Lunacy Regulation Act of 1862.[1] To the doctrine of moral insanity he offered an uncompromising but ineffective and, it must be confessed, an ignorant opposition. It is doubtful whether he understood the meaning, and it is certain that he had never studied the evidences, of the theory which he so severely condemns. A writer who imagined that the cases of Oxford and MacNaughten bore any resemblance to the "observations" of Pinel was hardly qualified to criticise even the less worthy of his disciples. Yet this hostility was not altogether irrational. Exaggerating, indeed mistranslating, the language of Pinel, in whose work moral insanity appears as "manie sans délire," the English alienists had pressed into their service cases which were far less closely allied to insanity than to crime, and had claimed, in the name of science, to return the verdict whenever mental incompetence existed or was presumed. Against these extravagant pretensions the school of Alderson and Rolfe arose in healthy revolt. Ignorant of, or possibly not caring to sift, the residuum of fact which undoubtedly they would have found in the standard literature of "manie sans délire," they believed moral insanity to be nothing more than the immoral and illogical plea with which English alienists had made them familiar, and they sternly refused to recognize it. To the exertions of this school, of which Samuel Warren was a distinguished member, we owe the wise jealousy with which the defence of moral insanity is now regarded by alienists themselves. See Warren's *Miscellanies*, vol. ii., "High Treason and Murder—Moral Insanity" (1854); also *The Windham Trial*, published by Wm. Olliver.

WARRINGTON, a municipal and parliamentary borough and market-town of England, chiefly in Lancashire but partly in Cheshire, is situated on the Mersey, near the Sankey Canal, and on the London and Northwestern main line and several branch lines of other railways, 18 miles west-southwest of Manchester, 20 east of Liverpool, and 182 from London. The bridge across the Mersey, formerly forming the chief passage over the river from Lancashire to Cheshire, was partly destroyed on the approach of the rebels in 1745, was restored with a watch tower in the middle by parliament in 1747, was replaced by a wooden structure in 1812, and was rebuilt of stone in 1836 at a cost of £6000 [$29,160]. The parish church of St. Elphin, a cruciform building in the Decorated style, occupies the site of the ancient church, which was taken down about the beginning of the 15th century, the crypt being all of the old structure that now remains. The church now consists of chancel with chapels, nave, aisles, crypt, and embattled central tower and spire rising to the height of 300 feet. It was restored in 1859–67 at a cost of over £15,000 [$72,900]. Among the principal modern public buildings are the town-hall, formerly the seat of Colonel Wilson-Patten, now Lord Winmarleigh, purchased in 1872 at a cost of £20,000 [$97,200]; the museum and library, erected in 1857, enlarged by the addition of an art gallery and lecture-room in 1876, and again extended in 1881; the market hall (1857); the large covered market shed (1879, enlarged 1885); the public hall (1862); the public baths (1866); the school of art (1883); the infirmary and dispensary (1872); the infectious diseases hospital; and the Warrington clergy orphan institution (1697). The educational institutions include a free grammar school, founded by one of the Boteler family in 1526, and a blue coat school.

---

[1] It is substantially as follows: Under every commission, the inquiry shall be confined to the question whether or not the alleged lunatic is, at the time of such inquiry, of unsound mind, and no evidence as to his acts, demeanor, or state of mind at any time being more than two years before the date of the inquiry shall be receivable in proof of insanity, unless the judge or master shall otherwise direct.

Warrington, in the period before the introduction of railways, possessed special advantages through its connection with the Mersey and Irwell navigation, and it now enjoys unusual facilities for the transit of heavy goods both by canal and railway, while its situation midway between Manchester and Liverpool, and on the main line of the London and Northwestern Railway, forms one of the chief sources of its prosperity. It was referred to by Blome in 1683 as "a very fine and large town which hath a considerable market on Wednesday for linen cloth, corn, cattle, provisions, and fish, being much resorted to by the Welshmen." It was among the earliest of the manufacturing towns of Lancashire,—coarse linens and checks being the manufactures which at first formed its staple goods, and afterwards sailcloth and sacking. Perhaps it is now best known for its trade in heavy leather, the tanneries in its immediate neighborhood consuming on an average about 10,000 hides a week. It has also a great variety of important iron manufactures, including iron in bar, hoop, and wire rod, and files and tools and pins. There are, besides, soap factories, breweries, maltings, cotton mills, and glass-works. The town is divided into five wards, four of which are in Warrington proper, and one in Latchford. The corporation act as the urban sanitary authority. There is a commission of the peace and a police force. The gas supply is managed by the corporation, but the water supply is in the hands of a company. The population of the parliamentary borough (area 3783 acres) in 1871 was 33,050, and in 1881 it was 45,253. The population of the municipal borough (area 1442 acres) in the same years was 32,144 and 41,452.

Warrington is stated to have been an ancient British and Roman town, but there are no traces of a Roman settlement on the north side of the Mersey. On the south side, however, near Wilderspool there are a considerable variety of remains, which some identify with the station *Condate*. At Domesday, Warrington, under the name of Walintune, was at the head of a hundred now merged in West Derby. Its present name first occurs in the 12th century, when Matthew de Vilers gave the church of Warrington to the priory of Thurgarton. Shortly afterwards Warrington came into the family of Pincerna, or Boteler, the progenitors of the Butlers, earls and dukes of Ormonde. Sir William Boteler, who was high sheriff of the county, and governor of the castle of Lancaster, obtained for it, in 1255, from Henry III. the grant of a fair of three days' duration. In the 5th of Edward I. (1277) the charter was renewed, and another was obtained in 1285. About 1592 it was bought by the Irelands, and in 1631 it came into the possession of William Booth, father of Sir George Booth, first Lord Delamere. During the civil war it was held, in 1643, for the king by James, Lord Strange, seventh earl of Derby, who fortified it at great expense, and made it a centre for Royalist excursions, but after a siege of five days it surrendered to the Parliamentary troops. After the battle of Preston in 1648, the remnant of the duke of Hamilton's army under General Baillie rallied at Warrington, and possessed themselves of the bridge, but surrendered on the approach of Cromwell. Henry Booth, second Lord Delamere, was created earl of Warrington on his retirement from the chancellorship of the exchequer in 1690. The town received parliamentary representation in 1832, and was incorporated in 1847. Among persons of eminence connected with Warrington are Dr. Aikin, editor of the *Dictionary of General Biography*, Lucy Aikin, Mrs. Barbauld, John Kay, the clockmaker who assisted Arkwright in his mechanical experiments, and Dr. Joseph Priestley.

See *Warrington in* 1465, in Chetham Society's Publications, vol. xvii.; *Annals of the Lords of Warrington during the first Five Centuries after the Conquest, ibid.*, vols. lxxxvi. and lxxxvii.; *Homage Roll of the Manor of Warrington*, 1491-1517, in the publications of the Manchester Record Society, 1885; Kendrick, *Profiles of Warrington Worthies*, 1859.

WARSAW, a government of Russian Poland, occupies a narrow strip of land to the left of the lower Bug and of the Vistula from its junction with the Bug to the Prussian frontier, and is bounded by the Polish governments of Płock and Łomza on the N., Siedlce on the E., and Radom, Piotrkow, and Kalisz on the S. It has an area of 5623 square miles and in 1885 the population was 971,730, of whom 384,000 were then reckoned as living in the capital. It occupies the great plain of central Poland and Mazovia, and is low and flat, with only a few hills in the south, and along the course of the Vistula in the northwest, where the terraces on the left bank descend by steep slopes to the river. Terrible inundations often devastate the region adjacent to the confluence of the Vistula with the Narew and Bug, and marshes cover the low-lying grounds. The soil, which consists chiefly either of boulder clay, lacustrine clays, or sandy fluviatile deposits, is not particularly fertile. The Vistula traverses the government from southeast to northwest, and is joined by the Narew and Bug from the right, and by the Bzura from the left. It is an important channel of communication (see POLAND, vol. xix. p. 318).

The population consists of Poles and Mazurs (Roman Catholics, 76 per cent.), Jews (15 per cent.), and Germans (9 per cent.). The Great and Little Russians number only a few thousands, and the former are gathered chiefly in the towns.

Of the 3,256,800 acres registered, nearly two-thirds of which are arable land, 1,197,000 acres belong to the peasantry (70,724 households), 257,000 to the crown, and the remainder to 4526 small and 1190 large proprietors; 118,000 acres are under forests. In the west the Germans are rapidly colonizing the country, and it was reckoned in 1885 that no less than 373,000 acres, *i.e.*, nearly one-eighth of the territory, and a still larger proportion of the arable land, belonged to 4260 foreigners, chiefly Germans. Agriculture is the prevailing occupation, and reaches great perfection on some estates. Beet is extensively grown. Cattle-breeding is also of importance.

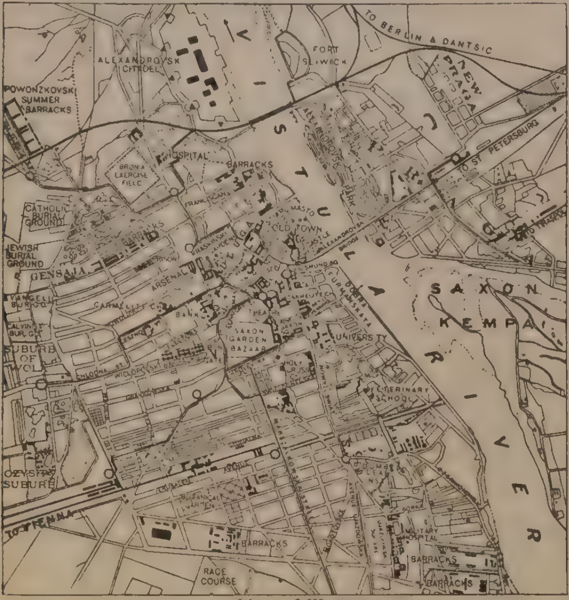
Manufactures have developed rapidly of late, especially in Warsaw and its vicinity. In 1885 there were 1575 establishments , employing 35,400 operatives, with an output valued at 54,700,000 roubles. Sugar works occupied a prominent place. In 1886 nineteen sugar works and refineries employed 8925 operatives, and produced 6,450,000 cwts. of raw and 3,220,000 of refined sugar. Plated silver, carpets, woollen cloth, machinery, boots and shoes, spirits and beer are among the other items produced.

The government is divided into thirteen districts, the chief towns of which are WARSAW (*q.v.*), Błonie (1370 inhabitants), Góra Kalwaria (2630), Gostynin (8870), Grojec (3500), Kutno (13,210), Łowicz (8720), Novo-Minsk (1830), Radziejewo (7680) Radzymin (4200), Skiernewice (3720), Sochaczew (5130), and Włoclawek (20,660). Novy Dwor (4420), Neszawa (2330), Gombin (3000), and several others have municipal institutions.

WARSAW (*Warszawa*), capital of Poland, and chief town of the above government, is beautifully situated on the left bank of the Vistula, 395 miles to the east of Berlin, and 700 miles to the southwest of St. Petersburg. It stands on a terrace nearly 100 feet in height, which stretches far to the westward, and descends by steep slopes towards the river, leaving a broad beach at its base. The suburb of Praga on the right bank of the Vistula, here from 450 to 880 yards broad, is connected with Warsaw by two bridges,—the railway bridge, which passes right under the guns of the Alexandrovsk citadel to the north, and the Alexandrovsk bridge in the centre of the town.

With its population of nearly 450,000, its beautiful river, its ample communications and its commerce, its university and scientific societies, its palaces and numerous places of amusement, Warsaw is one of the most pleasant as well as one of the most animated cities of eastern Europe. In Russia it is excelled in importance by the two Russian capitals only; and doubtless it would have attained even a larger population, and a yet higher place in the world of commerce and intellect, were it not for its sad and chequered history, and the foreign domination of which the traveller is reminded at every step.

Situated in a fertile plain, on a great navigable river, below its junction with the Pilica and Weprz, which waters southern Poland, and above its junction with the Narew and Bug, which water a wide region in the east, it became in mediæval times the chief entrepôt for the trade of those fertile and populous valleys with western Europe. Its position in the territory of Mazovia, which was neither Polish nor Lithuanian, and, so to say, remained neutral between the two rival powers which constituted the united kingdom, it became the capital of both, to the detriment of the purely Polish Cracow and the Lithuanian Vilna. And now, connected as it is by six trunk lines with Vienna, southwestern Russia, Moscow, St. Petersburg, Dantzic, and Berlin (*via* Bromberg), it has become one of the most important commercial cities of eastern Europe. The southwestern railway connects it with Łodz, the Manchester of Poland, as also with the rich coal fields of Kielce, which supply its steadily growing manufactures with coal and iron, so that Warsaw and its neighborhood have become a centre for all kinds of manufactures, greatly aided in their development by the high technical training and general superiority of the engineers of the Polish capital, as well as by the skill, taste, and intelligence of its artisans. The periodical wholesale deportations of Warsaw artisans, who never failed to take an active part in the Polish insurrections, especially in 1794, 1831, and 1863, considerably checked, but could not wholly stop the industrial progress of the town; but the lines of customhouses which surround Poland, and thus limit the Warsaw market, as also the Russian rule, which militates against the progress of Polish science, technology, and art, are so many obstacles to the development of its natural resources. The population of Warsaw has nevertheless grown rapidly of late, having risen from 161,008 in 1860, and 276,000 in 1872, to 436,570 in 1887; of these more than 25,000 are Germans, and one-third are Jews (43,000 in 1860, and 117,300 in 1879). The Russian garrison amounts to nearly 20,000 men.



Plan of Warsaw.

The streets of Warsaw are very animated, and are adorned with many fine buildings—partly due to the old Polish nobility's love of display (there are more than 160 palaces, 60 of which have been confiscated by the Russian government), partly churches and cathedrals (179 Catholic, 6 Greek, and 2 Lutheran, several synagogues, 14 monasteries, and 4 nunneries), and partly public buildings,—schools, hospitals, scientific societies,—erected at great expense by the municipality or by private bodies. Fine public gardens and several monuments further embellish the city. The present university, founded as the "Glawnaja Szkoła," in 1816, but closed in 1832, was again opened in 1864; it has a remarkable library of more than 350,000 volumes, rich natural history collections, a fine botanic garden, and an observatory well known for its astronomical work. There are 75 professors and nearly 1000 students. The teaching is in Russian, and mostly by Russians, and the close intercourse which used to exist between the university and the educated classes of Poland is becoming a thing of the past. The rich university library, one of the largest in the world, was confiscated in 1794, and transferred to St. Petersburg, where it became the nucleus of the present imperial public library; and after the insurrection of 1831, it was again ransacked for the same purpose. The medical school, which enjoys high repute in the scientific world, still retains the right of teaching in Polish, and has about 220 students. The same privilege is enjoyed by the school of arts, the academy of agriculture and forestry and the conservatory of music, all of which are high class institutions. There are, besides, six classical gymnasia, two "real" schools, and numerous elementary schools. The museum of the society of fine arts is rich in examples of ancient and modern art. The association of the friends of science and the historical and agricultural societies of Warsaw were once well known, but all were closed after the insurrections, and now they live but a precarious life, the scientific works which continue to be produced in Poland being partly published at Cracow.

The great theatre for Polish drama and the ballet is a fine building which really includes two theatres under the same roof; but the pride of Warsaw is its theatre in the Łazienki gardens, which were laid out in an old bed of the Vistula by Stanislaus Augustus Poniatowski and have beautiful shady alleys, artificial ponds, an elegant little palace with ceilings painted by Bacciarelli, several imperial villas, and a monument to Sobieski. An artificial ruin on an island makes an open-air theatre, the stage of which is separated from the auditorium by a channel of water, and the decorations of which blend with the parks and the palace behind. Two other public gardens, with alleys of old chestnut trees, are situated in the centre of the city. One of these, the, Saski Ogrod, or Saxon garden (17 acres), which has a summer theatre and excellent fountains, and is richly adorned with statues and flowers, is one of the most beautiful in Europe; it is the resort of the Warsaw aristocracy. The Krasinski garden, now somewhat less frequented, and many other smaller squares and gardens in the theatres of which Polish and German companies give their summer representations, contribute very much to the enlivenment of the streets of Warsaw; while the variety of smart national costumes still worn by the Polish peasantry gives color and brightness to the crowds which throng them.

Warsaw is semicircular in plan, the diameter, nearly 5 miles in length, lying along the Vistula. The central point of the life of the place is the castle (Zamek Królewski) on Sigismund Square. It was built by the dukes of Mazovia, enlarged by Sigismund III. (whose memorial stands opposite) and Ladislaus IV., and embellished by Stanislaus Augustus. At present it is inhabited by the "governor-general of the provinces on the Vistula," and its pictures and other art treasures have been removed to St. Petersburg. Four main thoroughfares radiate from it: one, the Krakowskie Przedmiescie, the best street in Warsaw, runs southward. It is continued by the Nowy Swiat and the Ujazdowska Aleja avenue, which leads to the Łazienki gardens. Many fine buildings are found in these two streets: the church of the Bernardine convent; the house of the benevolent society; the Carmelite church, now closed, where the crown archives of Poland are still kept; the rich Radziwill palace, now inhabited by the governor-general; the university, Saxon Square, on which Nicholas I. ordered the erection of a memorial to the Polish generals who refused to take part in the insurrection of 1831 and were therefore shot by the insurgents; the Saxon garden behind the square; the fine palaces of the Potockis, the Oginskis, the Uruskis, etc.; the church of the Holy Cross, erected in 1682–96, the richest in Warsaw; the palace of the Krasinskis, with library and museum; the statue of Copernicus, by Thorwaldsen, erected in 1822 by national subscription; the house of the friends of natural history, now a gymnasium; the palace of the Zamojskis, now confiscated and transformed into a building for subalterns of the garrison; the church of St. Alexander, erected to commemorate the re-establishment of the kingdom of Poland; and the deaf and dumb asylum. The Ujazdowska Aleja avenue, planted with lime-trees and surrounded by cafés and various places of amusement, is the Champs Elysées of Warsaw. It leads to the Łazienki park, and to the Belvedere palace, now the summer residence of the governor-general, and farther west to the Mokotowski parade ground, which is surrounded on the south and west by the smoky chimneys of the manufacturing district. Another great street, the Marszałkowska, runs parallel to the Ujazdowska from the Saxon garden to this parade ground, on the southeast of which are the Russian barracks. The above-mentioned streets are crossed by another series running west and east, the chief of them being the Senatorska which begins at Sigismund Square and contains the best shops. The palace of the archbishops of Gnesen and primates of Poland, confiscated by the Prussian government, and now used by the ministry of education, the bank of Poland, the fine mansion-house burned in 1863 and now rebuilt as police bureau, the small Pod Blachoi palace, now occupied by a chancery, the theatre, the old mint, the chief post-office, the beautiful Reformed Church, the exchange, the school of subaltern officers, and several palaces are grouped in Senators' Street, which is joined from the north by Miodowa Street, in which are situated the fine church of the Capuchins, erected in 1683 to commemorate the victory of John Sobieski over the Turks, the palace of the archbishops of Warsaw, and the Russian cathedral.

To the west Senators' Street is continued by Electors' Street, where is the very elegant modern church of St. Charles Borromeo and the Chłodna leading to the suburb of Wola, with a large field where the kings of Poland used to be elected. In Leshno Street, which branches off from Senators' Street, are the Zelazna Brama, or Iron Gate, in the market-place, the gostinyi dvor or bazaar, the arsenal, and the Wielopolski barracks. The cemeteries, the summer barracks of the troops (Powonzski lager), and the artillery barracks lie to the northwest.

To the north of Sigismund Square is the old town—Staro Miasto—the Jewish quarter, and farther north still the Alexandrovsk citadel. The old town very much recalls old Germany by its narrow streets and old buildings; it has the church of St. John at its entrance, and farther down the cathedral, which is the oldest church of Warsaw, having been built in the 13th century and restored in the 17th. The citadel, erected in 1832–35 as a punishment for the insurrection of 1831, is of the old type, with six forts too close to the walls of the fortress to be useful in modern warfare. The railway bridge, built in 1865 and 570 yards long, begins under the walls of the citadel and is protected on the right bank of the Vistula by the Sliwnicki *tête de pont.*

The suburb of Praga, on the right bank of the Vistula, is poorly built and often flooded; but the bloody assaults which led to its capture in 1794 by the Russians under Suwaroff, and in 1831 by Paskevitch, give it a name in history.

Industry and Trade.—Warsaw has of late become industrially important, and now has more than 320 establishments employing nearly 20,000 workmen, and producing to the amount of nearly 40 million roubles [$30,800,000] annually. The leading industries are the production of plated silver ware, with a wide market throughout Russia, machinery and engines, chemicals, musical instruments, especially pianos, carpets, boots and shoes, largely exported, carriages, woollen cloth, leather wares, spirits, and beer. The trade of Warsaw is considerable. Nearly 14,000,000 cwts. of coal and 4,800,000 cwts. of miscellaneous goods are imported by rail from the southwest (Kielce, Łodz, and Galicia), and 3,200,000 cwts. of manufactured goods, corn, flax, etc., are exported in the same direction. Corn and flax are imported to the amount of 7,000,000 cwts. from the southeast and east, and exported to Prussia to the amount of 5,300,000 cwts. by rail and partly down the Vistula, while the total railway traffic is represented by 34,400,000 cwts. of merchandise brought in and 18,000,000 cwts. sent away. To all this must be added the traffic on the Vistula (about 3,000,000 cwts.). A great proportion of the trade is in the hands of Germans, especially of Jews.

The suburbs of Warsaw are surrounded by villas, palaces, and battlefields. Wilanow, the palace of John Sobieski, now belonging to the Potockis, was partly built by Turkish prisoners in a fine Italian style, and is now renowned for its historical portraits and pictures. It is situated to the south of Warsaw, together with many other fine villas (Morysin, Natolin, Krolikarnia, which also has a picture gallery, etc.) The Marymont, an old country residence of the wife of John Sobieski, and the Kaskada, much visited by the inhabitants of Warsaw, in the north, the Saska Kempa on the right bank of the Vistula, and the castle of Jabłona down the Vistula are among others that deserve mention.

The events associated with the name of Praga have been already alluded to. Among other battlefields in the neighborhood of Warsaw is that of Grochowo, where the Polish troops were defeated in 1831 after a gallant fight. Raszyn saw its fields covered with blood in the war of 1809 with Austria; at Maciejowice, 50 miles up the Vistula, Kosciuszko was wounded and taken by the Russians in 1794; and 20 miles down the river stands the fortress of Modlin, now Novogeorgievsk, fortified by Napoleon, taken in 1813 by the Russians, and the last stronghold of the Poles during the insurrection of 1831.

History.—The history of Warsaw from the 16th century onwards is intimately connected with that of POLAND (*q.v*). The precise date of the foundation of the town is not known. The banks of the Vistula between the Pilica and the Narew must have been inhabited from a very early period, and it is supposed that Conrad, duke of Mazovia, erected a castle on the present site of Warsaw as early as the 9th century. Casimir the Just is supposed to have fortified it in the 11th century, but Warsaw is not mentioned in annals before 1224. Until 1526 it was the residence of the dukes of Mazovia, but when their dynasty was extinguished the land of the Mazurs, till then independent, was annexed to Poland. When Poland and Lithuania became united, it was chosen as the royal residence. Sigismund Augustus (Wasa) made it the real capital of Poland, and from 1572 onwards the election of the kings of Poland took place on the field of Wola. From the 17th century possession of it was continually disputed by the Swedes, the Russians, and the Brandenburgers and the Austrians. Charles Gustavus of Sweden took it in 1655 and kept it for a year; the Poles retook it in July, 1656, but lost it again almost immediately. Augustus II. and Augustus III. did much for its embellishment, but it had much to suffer during the northern war. Charles XII. took it in 1702, but in the following year peace was made between the Swedes and Stanislaus Lezczynski, and it became free again. The disorderly rule of the Rzec Pospolita opened a large field for Russian intrigue, and in 1764 the Russians took possession of it and secured the election of Stanislaus Poniatowski, which led in 1773 to the first partition of Poland. In November, 1794, the Russians took it again, after the bloody assault on Praga, but next year, in the third partition of Poland, Warsaw was given to Prussia. In November, 1806, the town was occupied by the troops of Napoleon, and after the peace of Tilsit was made the capital of the independent duchy of Warsaw; but the Austrians took it on April 21, 1809, and kept it till June 2, when it once more became independent, but only for a few years. The Russians finally took it on February 8, 1813, since which time they have always retained it. On November 29, 1830, Warsaw gave the signal of the great but unsuccessful insurrection which lasted nearly one year; it was taken after great bloodshed by Paskevitch, on September 7, 1831. Deportations on a large scale, executions and confiscation of the domains of the nobility followed, and until 1856 Warsaw remained under severe military rule. In 1862 a series of demonstrations began to be made in Warsaw in favor of the independence of Poland, and after a bloody repression a general insurrection followed in January, 1863, the Russians remaining, however, masters of the situation. The Russian Government now decided to take the most stringent measures to crush the powers of the clergy, the landed nobility, and the turbulent Warsaw artisans and educated classes. Executions, banishment to the convict prisons of Siberia, and confiscation of estates followed. Deportation to Siberia and the interior of Russia was carried out on an unheard-of scale. Scientific societies and high schools were closed; monasteries and nunneries were emptied. Hundreds of Russian officials were called in to fill up administrative posts, the schools, and the university; the Russian language was rendered obligatory in official acts, in all legal proceedings, and even, to a great extent, in trade. The very name of Poland was expunged from official writings, and, while the old institutions were abolished, the Russian tribunals and administrative institutions were introduced. The serfs were liberated. See POLAND.

Officially, Warsaw is now simply the chief town of the government of Warsaw, the residence of the governor-general of the provinces on the Vistula and the commander of the Warsaw military district, and the see of the Roman and Greek archbishops. But it continues to be the heart of the Polish nationality. (P. A. K.)

WART is a papillary excrescence of the surface, most commonly of the skin, but in special circumstances also of the transitional and mucous membranes. The ordinary broad and flat warts of the skin occur mostly upon the hands of children and young persons; a long pendulous variety occurs about the chin or neck of children who are constitutionally delicate (it used to be thought a mark of scrofula) and on the scalp in adults. Both the broad sessile warts of the fingers or hands and the thin hanging warts of the neck and head are apt to come out in numbers at a time; a crop of them suddenly appears, to disappear after a time with equal suddenness. Hence the supposed efficacy of charms. A single wart will sometimes remain when the general eruption has vanished. The liability to crops of warts runs in families. In after life a wart on the hands or fingers is usually brought on by some irritation, often repeated, even if it be slight. A special form has been observed on the hands of those much occupied with anatomical dissection. Chimney-sweeps and workers in coal-tar, petroleum, etc., are subject to warts, which often become cancerous. Ordinary innocent warts occur singly in later life on the nose or lips or other parts of the face, sometimes on the tongue. Towards old age there are apt to be broad and flattened patches of warts on the back, of a greasy consistence and brownish color.

A wart consists essentially of a framework or ground-plan of small bloodvessels supported by bands of fibrous tissue, and a more or less thick covering of epidermic scales. When the wart is young, the surface is a rounded and even knob; as it gets rubbed and worn the surface appears cleft into thread-like projecting points. The bloodvessels, whose outgrowth from the surface really makes the wart, may either be in a cluster of parallel loops, in which case we have the common broad and sessile wart, or the vessels may branch from a single stem, making the dendriform pattern of the long, slim, and pendulous warts of the chin and neck. The same two kinds of pattern occur also in warts of the transitional or mucous surfaces. (For a figure of a dendriform wart, see PATHOLOGY, vol. xviii. Fig. 43, p. 386.) A wart of either pattern is a projection of the system of cutaneous bloodvessels beyond the surface. It is owing to its vascular ground-plan that a wart is liable to come back after being shaved off; the vessel or vessels are cut down to the level of the skin, but the current of blood is still forced into the stem, and the branches tend to be thrown out beyond the surface as before. This fact has a bearing on the treatment of warts. If they are shaved or snipped off, the bloodvessels of the stem should be destroyed at the same time by caustic, or made to shrivel by an astringent. The same end is served by a gradually tightening ligature (such as a thread of elastic pulled out from an old brace) round the base or neck of the wart; an ordinary thread is apt to cut too deep and may cause suppuration. The best treatment is to rub an astringent, or acid, or caustic substance into the surface of the wart. Glacial acetic acid may be applied on the end of a glass rod, or by a camel-hair brush, care being taken not to touch the adjoining skin. A solution of perchloride of iron is also effective in the same way. Nitrate of silver is objectionable, owing to the black stains left by it. A simple domestic remedy, often effectual, is the astringent and acrid juice of the common stonecrop (*Sedum acre*) rubbed into the wart, time after time, from the freshly gathered herb. The result of these various applications is that the wart loses its turgor or firmness, shrivels up, and eventually falls off.

A peculiar form of wart, known as *verrugas*, occurs endemically in certain valleys of the Peruvian Andes, especially in the region of the Cerro de Pasco. It is believed to have been one of the causes of the excessive mortality from hæmorrhages of the skin among the troops of Pizarro. In recent times attention was called to it by Dr. Archibald Smith in 1842; in 1874, during the making of the Trans-Andean Railway, it caused a considerable loss of life among English navvies and engineers. Strangers of the white race suffer much more severely from it than the acclimatized or the natives. It is sometimes epidemic and peculiarly fatal. Its endemic seats are certain deep and narrow valleys traversed by a mountain stream or torrent and covered with luxuriant vegetation; where the valley widens the endemic influence is no longer felt. The warts may be few or many, up to several hundreds; they occur on internal mucous membranes as well as on the skin. Their outbreak is preceded for some weeks by a feverish state and by pains in the limbs. These symptoms disappear when the warts come out; they are at first reddish spots about the size of a pea, but grow to be rounded or conical excrescences as large as a raspberry or filbert, or pigeon's egg; after a time the surface becomes ragged or fissured (as in an ordinary wart), especially when rubbed or chafed, and blood begins to ooze, which may amount to considerable hæmorrhage. Death (in about 10 per cent. of cases) is due to loss of blood, or to the protracted ulceration following the fall of the warts. The disease lasts usually several months; but a feeble state of the system may remain long after the warts are all gone. The excrescences (besides those of the internal membranes) occur in the favorite situations of common warts—the fingers and back of the hand (also the toes and back of the foot), the face and neck, and among the hair of the head.

See Hirsch, *Geographical and Historical Pathology*, vol. ii., Engl. trans., 1885.

WARTON. Three authors of this name, a father and two sons, were leaders of reaction against the didactic poetry of Pope's school, and did much to help forward the descriptive and romantic revival.

THOMAS WARTON (1688–1745), satirized in *Terræ Filius* (February 18, 1721) as "squinting Tom of Maudlin," was vicar of Basingstoke in Hampshire, and professor of poetry at Oxford. He published nothing during his lifetime, but after his death his son Joseph published some of his poetry under the title *Poems on Several Occasions*, 1748.

JOSEPH WARTON (1722–1800), eldest son of the preceding, was born at Dunsford, in Surrey, in 1722, and sent to Winchester school in 1736. Collins was already there, and the school seems to have been at the time quite a nest of singing birds, quickened into unusual ambition by a visit from Pope. Collins and Warton became close friends, read Milton and Spenser together, and wrote verses which they sent to the *Gentleman's Magazine*, verses of such promise that Johnson formally criticized them. The two friends went to Oxford together, and took the degree of B.A. in the same year (1743). Warton was far from having the genius of Collins, but he had abundance of poetical enthusiasm, and they were at one in their impatience under the prevailing taste for moral and ethical poetry. Whoever wishes to understand how early the discontent under Pope's ascendency began should read Warton's *The Enthusiast*, or *The Love of Nature*, and remember that it was written by an undergraduate in 1740, while Pope was still alive. Warton sounded a bold note in 1746, in the preface to his *Odes on Several Subjects*. "As he is convinced," he wrote, "that the fashion of moralizing in verses has been carried too far, and as he looks upon invention and imagination to be the chief faculties of a poet, so he will be happy if the following odes may be looked upon as an attempt to bring back poetry into its right channel." Warton thereafter married, became a country clergyman, a master in Winchester school, eventually for thirty years (1766–96) a much respected headmaster, but all his leisure was given to literature, and he remained

constant to his conception of the "right channel" in poetry, though he soon abandoned the idea of setting the world right by his own example. He became an active and prominent man of letters, produced an edition of Virgil, in 1753, with distinguished coadjutors, and a translation of the *Eclogues* and the *Georgics*, and a preparatory essay by himself; made the acquaintance of Johnson, and wrote papers on Shakespeare and Homer in *The Adventurer*; published the first part of an essay on Pope in 1756, an essay regarded at the time as revolutionary, by Dictator Johnson at least, because it put Pope in the second rank to Shakespeare, Spenser, and Milton, on the ground that moral and ethical poetry, however excellent, is an inferior species; held his own against Johnson in the Literary Club; and, after enduring many jests about the promised second part and the delay in its appearance, published it at last, retracting nothing, in 1782. Of this essay Campbell justly says that "it abounds with criticism of more research than Addison's, of more amenity than Hurd's or Warburton's, and of more insinuating tact than Johnson's." Warton's edition of Pope was the work of his old age; when published in 1797, it found a larger number of sympathizers with his criticism of the poetic idol of the 18th century than had welcomed his first essay forty years before in the same vein. The last three years of the critic's life were spent in preparing an edition of Dryden, which was completed and published by his son in 1811. He died in London in February, 1800, at the age of seventy-eight.

THOMAS WARTON (1728–1790), the younger brother of Joseph, at least as active and influential as he in enlarging the poetic ideas of the 18th century, was born at Basingstoke in 1728. He was still more precocious as a poet than his brother—translated one of Martial's epigrams at nine, and wrote *The Pleasures of Melancholy* at seventeen—and he showed exactly the same bent, Milton and Spenser being his favorite poets, though he "did not fail to cultivate his mind with the soft thrillings of the tragic muse" of Shakespeare. He wrote as follows in 1745:

> Through Pope's soft song though all the Graces breathe,
> And happiest art adorn his Attic page,
> Yet does my mind with sweeter transport glow,
> As, at the root of mossy trunk reclined,
> In magic Spenser's wildly warbled song
> I see deserted Una, etc.

In the same poem he shows the delight in Gothic churches and ruined castles which inspired so much of his subsequent work in romantic revival. Most of Warton's poetry, humorous and serious,—and the humorous mock heroic was better within his powers than serious verse,—was written before the age of twenty-three, when he took his M.A. degree and became a fellow of his college (Trinity, Oxford). He did not altogether abandon verse; his sonnets, especially, which are the best of his poems, were written later, and during the last six years of his life he was poet-laureate, and one of the happiest in the execution of the delicate duties that have ever held the office. But his main energies were given to omnivorous poetical reading and criticism. He was the first to turn to literary account the mediæval treasures of the Bodleian Library. It was through him, in fact, that the mediæval spirit which always lingered in Oxford first began to stir after its long inaction, and to claim an influence in the modern world. Warton, like his brother, entered the church, and held, one after another, various livings, but he did not marry. He gave little attention to his clerical duties, and Oxford always remained his home. He was a very easy and convivial as well as a very learned don, with a taste for pot-houses and crowds as well as dim aisles and romances in manuscript and black letter. The first proof that he gave of his extraordinarily wide scholarship was in his *Observations on the Poetry of Spenser*, published in 1754, when the author was twenty-six. Three years later he was appointed professor of poetry and held the office for ten years, sending round, according to the story, at the beginning of term to inquire whether anybody *wished* him to lecture. The first volume of his monumental work, *The History of English Poetry*, appeared twenty years later, in 1774, the second volume in 1778, and the third in 1781. A work of such enormous labor and research could proceed but slowly, and it was no wonder that Warton flagged in the execution of it, and stopped to refresh himself with annotating the minor poems of Milton, pouring out in this delightful work the accumulated suggestions of forty years. Specialists may here and there detect errors and imperfections in Warton's *History*, but its miscellaneous and curious lore must make it always an interesting book, while its breadth and exactness of scholarship must always command wonder and respect. Through this work Warton became the veritable literary father of Sir Walter Scott; if he could have lived to read the *Lay* and *Marmion* he would have found realized there what he vaguely desiderated in modern poetry. Among Warton's minor works were a selection of Roman metrical inscriptions (1758); the humorous Oxford *Companion to the Guide* and *Guide to the Companion* (1762); *The Oxford Sausage* (1764); an edition of Theocritus (1770); lives of Thomas Pope and Bathurst, college benefactors; a *History of the Antiquities of Kiddington Parish*, of which he held the living (1781); and an *Inquiry into the Authenticity of the Poems attributed to Thomas Rowley* (1782). His busy and convivial life was ended by a paralytic stroke in May, 1790. (W. M.)

WARWICK, a midland county of England, is bounded on the N. by Stafford, on the E. by Leicester and Northampton, on the S. by Oxford and Gloucester, and on the W. by Worcester. Its greatest length from north to south is 50 miles, and its greatest breadth 33 miles. Its area is 566,458 acres or about 885 square miles. Camden describes it as being "divided into two parts, the *Feldon* and *Woodland* [or Arden], that is into a plain champain and a woody country; which parts, the Avon, running crookedlie from northeast to southwest, doth, after a sort, sever one from the other."

Plate VIII.

Surface and Geology.—The surface of the county is of a gently undulating nature. For a description of the scenery and early history the reader is referred to the article SHAKESPEARE, vol. xxi. pp. 774 *sq.*

The chief elevations are the Edge Hills on the southern border of the county, where they rise in some places to about 800 feet above sea-level. In the same neighborhood are the Burton Dassett and Farnborough Hills; northeast of these are the Napton and Shuckburgh Hills, and southwest of the Edge Hills is Brailes Hill. Some elevated land is found at Corley, Oldbury, Hartshill, etc., in the north of the county.

The lofty elevation of the county in general is evidenced by the fact that rivers flow from it in several directions, contributing to each of the three systems of the Severn, Trent, and Thames. The Avon rises in Northamptonshire, and flowing southwest through the county receives on its way the Swift, Sowe, Leam, Itchene, Stour, Alne, and other tributaries, and falls into the Severn at Tewkesbury. It is navigable for barges up to Stratford, and is rich in its associations with Shakespeare. The Tame rises in Staffordshire, and flowing through the northern portion of Warwickshire takes in the Cole, Blythe, Anker, Rea, and other minor streams. A few small rivulets in the south of the county fall into the Cherwell, a tributary of the Thames.

The New Red Sandstone is the principal geological formation of the county, but towards the south the Lias prevails. In the north central district there is a large deposit of gravel, which consists of "small boulders and sea-worn pebbles, and ancient rocks traceable to the parent beds in Yorkshire, Cumberland, and Scotland, and commonly known as the northern drift. Quartz pebbles especially abound in it; granite, gneiss, syenite, porphyry, slate, mica schist, trap, and almost every other variety of the primary rocks may be collected." The Lias is near Edge Hill; the strata immediately below it consist of clay and ironstone, rich in iron ore. The Upper Lias crosses the county by Henley-in-Arden, Stratford, Kineton, Southam, and Rugby. With the exception of one coal-field, small but rich, extending from Tamworth to near Wyken, about 15 miles, the New Red Sandstone and Permian occupy the whole of the central part of the county. In the north Upper Cambrian quartzites and shales are found together with some volcanic rocks. The Coal-Measures dip under the Lower Permian rocks, and in the southern part of the field underlie the Trias. According to the report of the Coal Commission in 1871, the area of the Warwickshire coal-field is 30 square miles, the thickness of the coal being from 26 to 30 feet. The quantity raised in 1870 was 647,540 tons and in 1885, it was 1,281,724.

The minerals of the county are limestone, freestone, iron, blue flagstone, marl, and blue clay. The blue flagstone is found in many places, and ironstone at Bedworth, Oldbury, and Merevale. The limestone quarries are principally at Bearley, Grafton Court, Stretton, Princethorpe, Ufton, Harbury, Arlescote, Bidford, Newbold-on-Avon, Stockton, and Southam; freestone is found largely about Warwick, Leamington, Kenilworth, and Coventry.

Climate and Agriculture.—The climate is generally mild and healthy. The soil is on the whole good, and consists of various loams, marls, gravels, and clays, well suited for most of the usual crops. It is rich in pasture-land, and dairy farming is increasing. It has excellent orchards and market gardens, and possesses some of the finest woodlands in England. Nearly all the farm buildings are good; and many of the cottages of the laborers are exceedingly picturesque. There are many charming villages in the county. According to the agricultural returns, out of a total area of 566,458 acres there were 496,429 acres under cultivation in 1887, corn crops occupying 105,039 acres, green crops 31,411, rotation grasses 40,783, permanent pasture 308,689, and fallow 10,493; of the corn crops much the largest area was under wheat, which occupied 43,728 acres, barley occupying 16,290, oats 26,297, rye 256, beans 14,050, and pease 4418. Of the green crops turnips occupied 16,913 acres, potatoes 4936 acres, while 4198 were under mangolds, 114 under carrots, 971 under cabbage, etc., and 4279 under vetches and other green crops.

The number of horses in 1887 was 20,769, cattle 107,555, of which 37,080 were cows and heifers in milk or in calf, sheep 294,442, 172,151 of them one-year-old and above, and pigs 37,092.

According to the *Return of Owners of Land*, 1873, the total number of proprietors in the county was 51,516, possessing 541,022, acres, with a gross annual rental of £3,318,304 [$16,126,957.44], or about £6, 2s. 8d. [$29.80] per acre all over. Of these owners of land only 4622 had one acre and upwards. Of waste or common land there was 1833 acres. The following possessed over 5000 acres: Lord Leigh, 14,892 acres; Lord Willoughby de Broke, 12.621; earl of Aylesford, 12,159; marquis of Hertford, 10,282; earl of Craven, 8448; earl of Warwick, 8263; Sir N. W. Throckmorton, 7619; duke of Buccleuch, 6881; H. J. Lucy, 5766; W. S. Dugdale, 5689; Sir G. R. Philips, 5397; and C. N. Newdegate, 5318.

Manufactures.—The principal seats of manufacture in the county are BIRMINGHAM and COVENTRY (*qq.v.*). Suffice it to say here that in Birmingham almost every article of use, from a pin to a steam engine, is produced, and that Coventry has long been famous for its ribbons and watches, and has recently won a well-merited reputation for bicycles and tricycles.

Communication.—The county is well supplied with excellently preserved roads. There are also a great number of canals giving access to the Trent, the Mersey, the Thames, and the Severn. The London and Northwestern, the Great Western, the Midland, and various branch railways traverse the county in various directions.

Population and Administration.—The population in 1871 was 634,189, and in 1881 737,339 (357,146 males and 380,193 females). More than half the population is contained in the borough of Birmingham. The county is divided into four hundreds: (1) Hemlingford, (2) Knightlow, (3) Barlichway, (4) Kineton. It has one city, Coventry (42,111), which is also a municipal borough; five other boroughs—Birmingham (400,774), Leamington (22,979), Stratford-on-Avon (8054), Warwick (11,800), and Sutton Coldfield (7737); and, besides the boroughs, ten market towns, viz., Alcester (2430), Atherstone (4645), Coleshill (2356), Henley in Arden (1119), Kenilworth (4150), Kineton (1053), Nuneaton (8465), Rugby (9891), Solihull (5280), and Southam (1784). It is mostly in the diocese of Worcester. It is in the midland judicial circuit, has one court of quarter sessions, and is divided into fourteen petty and special sessional divisions. The boroughs of Birmingham and Warwick have separate courts of quarter sessions and commissions of the peace, and the city of Coventry and the boroughs of Leamington and Stratford-on-Avon have commissions of the peace.

By the Redistribution Bill of 1885 Warwickshire was for parliamentary purposes divided into four boroughs and four county divisions. The boroughs are Birmingham, Aston Manor, Coventry, and Warwick and Leamington united. Birmingham has seven divisions, each returning a member—Bordesley, Central, East, Edgbaston, North, South, and West; the other three boroughs return one member each. The county divisions (Nuneaton, Rugby, Stratford-on-Avon, and Tamworth) each return one member.

History and Antiquities.—Warwickshire was occupied by the British tribes Cornavii and Dobuni. The Romans named this part of England Flavia Cæsariensis, and many evidences of their occupation and works exist in the county. It was crossed by the three great roads—Watling Street, the Fosse Way, and Icknield Street; the last-named gives its name to a street in Birmingham which is on the lines of the old Roman road. The Ridgeway borders a part of Warwickshire on the west. Roman stations or camps were at Mancetter, High Cross, Alcester, Chesterton, and other places; coins, pottery, and other remains have been found at Warwick, Willoughby, Hampton-in-Arden, Birmingham, and elsewhere. The Teutons followed the Romans, and after suffering many changes Warwickshire became part of Mercia. From 593 to 918 it was the scene of frequent invasions, conquests, and reconquests.

Although Mercia was for the most part peopled by Angles, the Saxons seem to have occupied the portion now known as Warwickshire in very considerable numbers; for, if we except Alcester, Mancetter, and a few other places, nearly all the towns and villages have Saxon names. Of the three hundred and sixty places in the county mentioned in Domesday nearly all are of Saxon origin. As Verstegan says,

"In Foord, in Ham, in Ley, in Tun,
The most of English surnames run."

And these terminations are found in the vast majority of the names of places in Warwickshire. This prevalence of the Saxons here is also confirmed by the fact that Mr. Kemble discovered no fewer than thirty-one Mark names in places in Warwickshire. The Danes, although they made inroads into Warwickshire several times, seem to have made no settlements in the county, the only names bearing the Danish suffix *by* being on the northeast border. In later times the "king-maker" earl of Warwick made the county memorable by the part he took in the Wars of the Roses. In the civil war under Charles I. "scarcely a place of any note escaped" without a struggle: at Edge Hill the first engagement was fought; Aston Hall was besieged; Birmingham was sacked and burned by Prince Rupert; Coventry endured a siege; Warwick was the centre of several encounters; and a skirmish took place near Southam.

Few remains of Saxon architecture are to be found in the county, and these are of minor importance. Saxon jewels have been found at Compton-Verney; a fine burial urn filled with ashes, an iron sword, a spear head, and other relics, at Church Over; in a tumulus or barrow, at Marston, were found two sepulchral urns, one of them containing bones, a fibula, a pin, part of a sword, and two spear heads. In 1824 an Anglo-Saxon cemetery was discovered on Watling Street, near Bensford Bridge, in which a large number of articles, both of use and ornament, were found. Other burial places have been opened, and similar remains found. Some good examples of Norman work exist in the churches at Kenilworth, Ryton, Stoneleigh, Burkeswell, Wolston, and Beaudesert. Of famous and interesting places may be mentioned the noble structure Warwick Castle; the ruins of Kenilworth Castle and Maxstoke Priory; Maxstoke Castle; Compton Wyniates; Temple Balsall church; the "three tall spires" at Coventry, with the beautiful churches of St. Michael, Holy Trinity, and St. John Baptist; Ragley Hall, Combe Abbey, Wroxhall Abbey, Newnham Padox, Astley Castle, Arbury Hall, Walton Hall, Guy's Cliff, Baddesley Clinton, Tamworth Castle and church, Packington Hall, and Stoneleigh Abbey.

Among the eminent persons connected with Warwickshire besides William Shakespeare are John Rogers the martyr, Michael Drayton, Sir W. Dugdale, Dr. Parr, Dr. Joseph Priestly, Matthew Boulton, John Baskerville, Walter Savage Landor, and Marian Evans ("George Eliot").

See Dugdale, *Antiquities of Warwickshire*, Thomas's edition (2 vols. fol. 1730); Brewer, *Description of Warwickshire* (8vo, 1810); Murray, *Agriculture of Warwickshire* (8vo, 1813); Smith, *History of Warwickshire* (4to, 1830); Langford, *Staffordshire and Warwickshire* (4 vols. 4to, 1868); Langford, "The Saxons in Warwickshire" (*Birmingham Archæological Society*, 4to. 1881).

WARWICK, the county town of Warwickshire, and a municipal and parliamentary borough, is finely situated on the Avon, on the Warwick and Birmingham and Warwick and Napton Canals, and on a branch of the Great Western Railway, 8 miles northeast of Stratford-on-Avon and 108 northwest of London. The glory of Warwick is still its castle, which has been truly pronounced to be the "most magnificent of the ancient feudal mansions of the English nobility still used as a residence." Its position is at once commanding and picturesque, standing as it does on a rock overhanging the Avon. Its principal features are Cæsar's Tower, 147 feet high, built in the 14th century; the Gateway Tower, in the centre; and Guy's Tower, 128 feet, also of the 14th century. There is a fine collection of pictures. The Great Hall and the family apartments were destroyed by fire in 1871, but have been restored. In the collegiate church of St. Mary Warwick possesses one of the most interesting ecclesiastical buildings in the country. We learn from Domesday that a church existed before the Conquest, but of its foundation nothing is really known. It was made collegiate by Roger de Newburgh, the second Norman earl. It was dissolved by Henry VIII. in 1545, by whom it was granted to the burgesses of the town, with an estate then worth £58,14s. 4d. [$481.73] to maintain it, together with the king's school. A great part of the church was destroyed by fire in 1694, and afterwards rebuilt. The glory of this church, however, is the Beauchamp Chapel, founded by Earl Richard Beauchamp by will, and commenced in 1443 and completed 1464. It is one of the finest examples of pure Gothic in the kingdom. In the centre of the chapel is the splendid tomb of the earl. The church of St. Nicholas, near the entrance to the castle grounds, is modern, with a tower and spire, and was erected towards the end of the 18th century. St. Paul's is new. The priory of St. Sepulchre was founded by Henry de Newburgh on the site of an ancient church for a society of canons regular. It is now a private residence. One of the most interesting places in Warwick is the hospital of Robert Dudley, earl of Leicester, one of the most picturesque examples of half-timber buildings in England. It was originally used as the hall of the united guilds of the Holy Trinity, the Blessed Virgin, and St. George the Martyr. The earl of Leicester, by an Act of Incorporation obtained in 1571, founded the hospital for the reception of twelve poor men possessing not more than £5 [$34.65] a year, and a master. The first master, appointed by the earl himself, was the famous Puritan, Thomas Cartwright. There are numerous charities in the town, the principal being those of Henry VIII., Sir Thomas White, and Thomas Oken. The first is derived from the tithes of St. Mary, St. Nicholas in Warwick, the parish of Budbrooke, and Chaddesley Corbett, Worcestershire, together with the rents of houses and lands in the borough. It produces about £3000 [$14,580] a year, and is used for paying the stipends of the vicar and an assistant minister for St. Mary's, the vicars of St. Nicholas and Budbrooke, the mayor, the town clerk, yeoman, serjeant-at-mass, and a beadle; while £460, 10s. [$2238.03] is annually given in aid of the king's school. By the charity of Sir Thomas White the sum of £100 [$486] is lent, without interest, to young tradesmen for a period of nine years. From the funds left for that purpose by Thomas Oken, allowances are made to the poor. The area of the borough is 5512 acres; the population in 1861 was 10,570, in 1871 10,986, and in 1881 11,800.

A fortress is said to have been erected here as early as the year 50, by P. Octavius Scapula, and it is supposed to have been the præsidium Romanorum at which a cohort of Dalmatian horse was stationed. It was destroyed by the Danes in one of their incursions into Mercia, and in 915 Alfred's daughter Ethelfleda built the fortress on which the castle now stands. The town is mentioned in Domesday, where we learn that "in the borough the king has in his demesne 113 houses, and the king's barons have 112, from which the king receives Danegeld. The bishop of Worcester has 9 dwellings, the bishop of Chester 7, the Abbot of Coventry 36, and four were destroyed to enlarge the castle." In the time of Edward the Confessor the sheriffwick of Warwick, with the borough and royal manors, rendered £65 [$850.90], and thirty-six sextars of honey, or £24, 6s. [$318.10] instead of honey (*pro omnibus quæ ad mel pertinebant*). Now, with the *forra* of the royal manors and pleas of the county, it pays per annum £145 [$1898.19] by weight, £23 [$301.09] for the custom of dogs, 20s. [$13.09] for a sumpter horse, £10 [$130.90] for a hawk, and 100s. [$65.45] for Queengold. Besides this it renders twenty-four sextars of honey of the larger measure, and from the borough six sextars of honey, at the sextar for 15d. [82 cts.]." The celebrated Thurkill (or Turchill) was the last Saxon earl of Warwick.

William the Conqueror began his first northern campaign in 1068, and the first place where his presence is distinctly recorded is Warwick. He erected here one of his strong fortifications on the site of the old one. Not a vestige of it now exists, but, as Mr. Freeman writes, "the mound itself still remains, a monument of the wisdom and energy of the mighty daughter of Ælfred, while the keep of William has so utterly perished that its very site can only now be guessed at."

Of the earls of Warwick who may be noticed, of course the legendary Guy, with the numerous traditions relating his wonderful achievements, stands first. In proof of his prowess do not his gigantic helmet, his furnace-like pot, and his mighty fork remain in the castle to this day, to testify against all unbelievers? Prominently in history we have Guy de Beauchamp, who came to the title in 1298, and who was called by the favorite Piers Gaveston "the Black Hound of Arden." He was instrumental in taking Piers prisoner, and in leading him to Blacklow Hill, close to Warwick, and there beheading him in 1311. Richard Nevil, the famous "king-maker" (see below), assumed the title in right of his wife Anne, and was slain at the battle of Barnet, 1471. Then the unfortunate George Plantagenet, duke of Clarence, was created earl by his brother Edward IV., but afterwards perished, it is said, by being drowned in a butt of Malmsey wine. The title has frequently lain dormant. In 1547 it was revived in favor of the Dudleys, when Viscount Lisle was created earl by Edward VI. It became extinct in 1589, and in 1618 was renewed in the person of Robert, Lord Rich, whose eldest son was lord high admiral for the Commonwealth. Again the title became extinct in 1759. The castle had long been in the possession of the Greville family, having been granted to Sir Fulke Greville, Lord Brooke, by James I. when it was in a ruinous condition, and he restored it, at a cost it is said, of £20,000 [$114,000]. Dugdale says he made it "not only a place of great strength, but extraordinary delight, with most pleasant gardens, walks, and thickets, such as this part of England can hardly parallel; so that now it is the most princely seat that is within the midland parts of this realm." He died from the effects of a wound inflicted by his own servant, September 8, 1628. His successor, Robert Greville, was the son of Fulke's first cousin, and is the Lord Brooke who is famous in the civil war between Charles and the Parliament, and was appointed commander-in-chief of the Parliamentary forces of Warwickshire and Staffordshire. He was engaged in the first fight of the war at Edge Hill, and was killed at the siege of Lichfield cathedral, on March 1, 1643. The title of earl of Warwick was bestowed on Francis, eighth Lord Brooke, by George II. in 1746. His son George, who succeeded to the title in 1773, was a great benefactor of the borough, and was lavish in his expenditure on the castle.

WARWICK, Richard Nevil, Earl of (*c.* 1420–1471), was born between 1420 and 1430. He was descended from a family of note in the north of England, that of the Nevils, who enjoyed for many generations the title of earls of Westmorland. His grandmother on the father's side was Joan, daughter of John of Gaunt. He inherited the title of earl of Salisbury from his father, a younger son of Ralph Nevil, and by his marriage with Anne, daughter of Richard Beauchamp, he became earl of Warwick. His descent from John of Gaunt made him naturally a member of the

Lancastrian party, but the marriage of his aunt, Cicely Nevil, to Richard, duke of York, connected him also with the Yorkist house. As first cousin of Edward IV. and second cousin of Henry VI. he was well fitted for the double part which he was destined to play in English history.

When the struggle between the Roses began, he and his father threw in their lot with the Yorkists. The first attempt of the duke of York (in 1450) to assert his claims proved unsuccessful, but three years later the final loss of Guienne, coupled with the king's imbecility, enabled him to renew his efforts. The duke became protector, but the king's recovery drove him from power and forced him to take up arms a second time. He was now joined actively by Warwick and his father, the former of whom raised a body of troops and contributed largely to the Yorkist victory at St. Albans (1455). Warwick was rewarded for his services with the governorship of Calais. This important post gave him the control of the narrow seas, and supplied him with a harbor of refuge whither he could safely retire in case of a change of affairs in England. In the latter capacity Calais soon proved useful.

In 1457, when Henry had recovered his senses, Warwick attended a council at Coventry, at which he took an oath of fealty to the king. Next year he attended a great meeting in London, summoned for the purpose of reconciling the two parties. He was followed on this occasion by six hundred men clad in his livery and wearing red coats embroidered with ragged staves, the badge of the house of Warwick. An apparent reconciliation was effected, but Warwick, accused of misconduct in attacking a fleet of North Sea merchant-ships near Calais, took advantage of an affray between his followers and some of the king's men to assert that a plot was laid against his life, and retired to his fortress across the channel. When in 1459 the duke of York took up arms for the third time, Warwick and his father, the earl of Salisbury, joined him at Ludlow. The confederates were strongly posted, but, being deserted by Sir Andrew Trollop, they lost heart and dispersed, Salisbury and Warwick again taking refuge at Calais. A parliament which met at Coventry now attainted Warwick and his father, with other leaders, of high treason, and Somerset was sent to supersede Warwick in his command. The latter, however made a strong resistance, repelled Somerset, and took his ships, after which he sailed to Dublin to concert further measures with the duke of York. The results of this negotiation were seen early in 1460, when the duke of York issued a manifesto to rouse the people against the Government, and Warwick, landing in Kent, marched on London. The king retired northward and entrenched himself at Northampton, where he was defeated with much loss by Warwick,and taken prisoner. Warwick returned with his captive to London, and the duke of York at once claimed the crown. After much debate the king was induced to consent to a compromise, by which he was to retain the crown during life, and the duke of York and his heirs were to succeed him. The queen, however, refused to sanction this arrangement, and assembled an army in the north. The duke of York, marching against her, was defeated and killed at Wakefield (December, 1460), and the earl of Salisbury was taken and beheaded shortly after. The Yorkist victory of Mortimer's Cross (1461) did not stop the queen's march on London, and Warwick, attempting to bar her progress, was entirely defeated at the second battle of St. Albans. The king fell into the hands of his own party, but Warwick escaped. The Lancastrian triumph was, however, short-lived. The citizens of London, already devoted to the house of York, were exasperated by the excesses of the Lancastrian troops, and when Warwick, with Edward,earl of March, raised another army and marched towards the capital, the queen was forced to retire to the north. Warwick and Edward entered the city, and the latter was proclaimed king under the title of Edward IV. The sanguinary battle of Towton (March, 1461), in which the victory was greatly due to the skill and energy of Warwick, secured the crown for Edward, and gave the nation peace for several years.

Honors and emoluments were showered on Warwick. The governorship of Guisnes and Dammes, with the lieutenancy of the marches there, was added to his command at Calais; he became warden of the western marches towards Scotland, constable of Dover, and lord high chamberlain. The revenue derived from these employments was calculated at 80,000 crowns ($222,200) a year. His brother, John, Lord Montague, was made earl of Northumberland and warden of the eastern marches, and his brother George became archbishop of York and lord chancellor. For some time Warwick did his best to maintain Edward on his throne. An attempt on the part of the Lancastrians in 1463 to recover their power was put down by the united efforts of the Nevils. Montague defeated Percy at Hedgeley Moor and Somerset at Hexham, while Warwick besieged and took Bamborough Castle, which was held by Sir Ralph Grey. Soon afterwards Henry VI. was taken prisoner and was lodged by Warwick in the Tower.

But the power and ambition of Warwick were too great to allow the good understanding between the king-maker and the king to be of long duration. The first difference between them arose on the question of the king's marriage. In 1464 Warwick was employed to treat for peace with France, and was anxious to establish it on the firm basis of a matrimonial alliance. His plans were frustrated by Edward's marriage with Elizabeth Woodville. At this time Warwick is said to have been negotiating for a marriage between the king and Bona of Savoy, niece of Louis XI. According to another authority, the princess proposed was Isabella of Castile. Whatever may be the truth of these reports, it is clear that Edward's marriage was not approved by Warwick, and that on the question of foreign policy they followed divergent aims. The rapid advancement of the queen's family contributed to widen the breach. When in 1467 a marriage was proposed between the king's sister Margaret and Charles of Burgundy, Warwick, true to his policy of reconciling England and France, vigorously opposed the match, and suggested in its stead a marriage with a French prince. For a time Edward seemed willing to yield, and Warwick was sent over to treat with the French king. He met him at Rouen, and was received with unusual marks of respect. The result of the conference was that ambassadors were sent by Louis to offer Edward a treaty on favorable terms. But the latter, who had already shown his displeasure by depriving the archbishop of his chancellorship, rejected the offer, and Warwick retired in disgust to one of his castles in the north. Shortly afterwards the marriage between Charles and Margaret took place. An apparent reconciliation between Edward and Warwick was now effected, but its hollowness was shown by the marriage of Isabella, eldest daughter of Warwick, with George, duke of Clarence, a match which Edward strenuously but vainly opposed (1468). A period of intrigue and insurrection followed. A rising in the north, under Robin of Redesdale, was at first defeated by Montague, but the rebels were allowed to make head again. They were soon joined by Warwick and his party, who, if they did not originate, at all events encouraged the rebellion. Edward, whose troops were defeated at Edgecote, fell into Warwick's hands, and was removed to his castle at Middleham. When, however, the Lancastrians took advantage of this state of affairs and rose in arms, they were speedily put down by Warwick. Edward was released and a formal reconciliation followed (1469).

The situation had, however, by this time become intolerable. A fresh insurrection broke out in Lincolnshire, and the confessions of the leaders, who were taken by the royal troops, showed that it had been instigated by Clarence and Warwick. The king at once marched against the conspirators, who in vain attempted to collect sufficient forces, and with some difficulty escaped from the country. Warwick made for his old stronghold at Calais, but his lieutenant proved faithless and turned his guns against him. Thereupon he took refuge at the court of France and resolved to side openly with the Lancastrians. A treaty was made between Warwick and Queen Margaret, which was cemented by the marriage of Prince Edward with Warwick's daughter Anne. This change of front naturally caused a coolness between Warwick and Clarence; but, before the latter could trim his course anew, Warwick, having obtained assistance from Louis XI., landed in the south of England. Edward was taken by surprise, and, unable to make any resistance, fled to Flanders. Warwick at once marched to London, released Henry VI. from captivity, and replaced him on the throne. A general restoration of property and position to the Lancastrians took place. Warwick and his brothers resumed their offices, and Clarence was recognized as successor to the throne in default of heirs-male to Henry VI. (1470).

But this turn of fortune was as brief as it was sudden. The house of Lancaster was finally overthrown by another revolution as capricious and inexplicable as any of those which had already marked this extraordinary conflict. Henry VI. had only been a few months on the throne when Edward, with the assistance of the duke of Burgundy, landed in Yorkshire, and gathering troops as he went, marched upon London. He was joined by "false, fleeting, perjured" Clarence, and admitted into the capital by Warwick's brother the archbishop. On Easter-Day, 1471, the forces of the king and the earl met at Barnet, and the former won a complete victory. The earl and his brother Montague were slain. Soon afterwards the battle of Tewkesbury and the death of Prince Edward extinguished the last hopes of the Lancastrian party.

The career of the king-maker is chiefly remarkable as illustrating the grandeurs and the evils of feudalism. Warwick's landed property was enormous, comprising, according to the deed by which his widow made it over to Henry VII., upwards of 110 manors in 21 counties, besides the city of Worcester, the islands of Guernsey, Jersey, Alderney, and Sark, and various places in Wales. Commynes tells us that at Calais he was so popular that every one wore his badge, "no man esteeming himself gallant whose head was not adorned with his ragged staff." Stow (*Annals*) says that "at his house in London six oxen were usually eaten at a breakfast, and every tavern was full of his meat, for who that had any acquaintance in his family should have as much sodden and roast as he could carry on a long dagger." In a time of civil war and a disputed title to the throne, such a man was naturally too strong for a subject. The restoration of order and the maintenance of the sovereignty of the state rendered inevitable the disappearance of the class so vigorously represented by the "Last of the Barons."

(G. W. P.)

WASHINGTON, the seat of government of the United States, forms a part of the District of Columbia, which is under the immediate government of the United States. The city of Washington as a corporation has had no existence since 1871, when Congress abolished the charters of that city and of Georgetown (also within the District of Columbia), and placed the entire District under one government.

The District of Columbia occupies an area of about 70 square miles, on the northeastern bank of the Potomac, about 100 miles above its mouth, and at the head of tide and of navigation. Most of its area is a plateau, elevated 300 to 400 feet above the river, and traversed by the Anacostia river and Rock creek. Just above the mouth of the former stream, the bluffs, which form the descent from the plateau, recede from the river, leaving an area of bottom land about 6 square miles in extent between that stream and the Potomac. This bottom land is undulating, much of it being but slightly elevated above the river, while the highest parts are scarcely more than 100 feet above high tide. The city of Washington is built upon this bottom land, while its immediate suburbs extend up the bluffs and over the plateau to the northward. The bluffs return to the river immediately above the city, and upon their slopes is built the old city of Georgetown, which is practically continuous with Washington. There are several suburban villages scattered over the district, including Mount Pleasant, Tenallytown, Brightwood, Le Droit Park, and Uniontown.

The climate of Washington is characterized by great humidity, long-continued but not excessive heat in summer, with mild winters. Snow does not often fall, and never lies long on the ground.

Three railroads enter the city, the Baltimore and Ohio and the Pennsylvania, which afford communication with the north and west, and the Richmond and West Point Terminal, which extends southward. Besides its railroad connections, regular lines of steamers ply to northern and southern ports during most of the year.

The plan of the city is regular and symmetrical. Radiating from the Capitol are three streets, running north, south, and east and known respectively as North, South, and East Capitol Streets. These, together with a line of public parks running west from the Capitol, divide the city into quarters, known as the northwest, northeast, southeast, and southwest quarters. The streets run in the cardinal directions, the north and south ones being designated by numbers, and the east and west ones by the letters of the alphabet,—the numbers increasing eastward and westward from the meridian of the Capitol, the letters progressing northward and southward from a parallel through that building. In addition to these streets, there is a system of avenues, which run diagonally to the cardinal directions, and which bear the names of States. The intersections of the streets and avenues have given opportunity for the construction of many small parks in the forms of triangles, circles, quadrilaterals, etc., which, with the numerous larger parks, scattered about the city, add greatly to its beauty and healthfulness. The streets have a total length of 233½ miles. They are wider than in any other city on the globe, the avenues ranging in width from 120 to 160 feet, while the streets range from 80 to 120 feet. The area comprised in the streets, avenues, and public parks is considerably more than half the area of the city. As the width of the streets is in most cases in excess of the demands of travel, a portion of this width has, in the residence streets, been left between the sidewalks and the houses, and has been improved as a public parking. In some cases, similar parking has been left in the middle of the streets. Of the 233½ miles of streets, 30 per cent. are paved with smooth pavements, either asphalt, coal-tar, concrete, or asphalt blocks; 10 per cent. are paved with granite or trap blocks, and an equal extent with cobble or rubble; 4½ per cent. are macadamized, and 14 per cent. are gravelled, while the remainder are unimproved. The paved streets are swept by machinery at frequent intervals. With the exception of the business streets every street is lined with shade trees, which, arching over the pavements, form continuous shade for miles. The trees are mainly elms and maples.

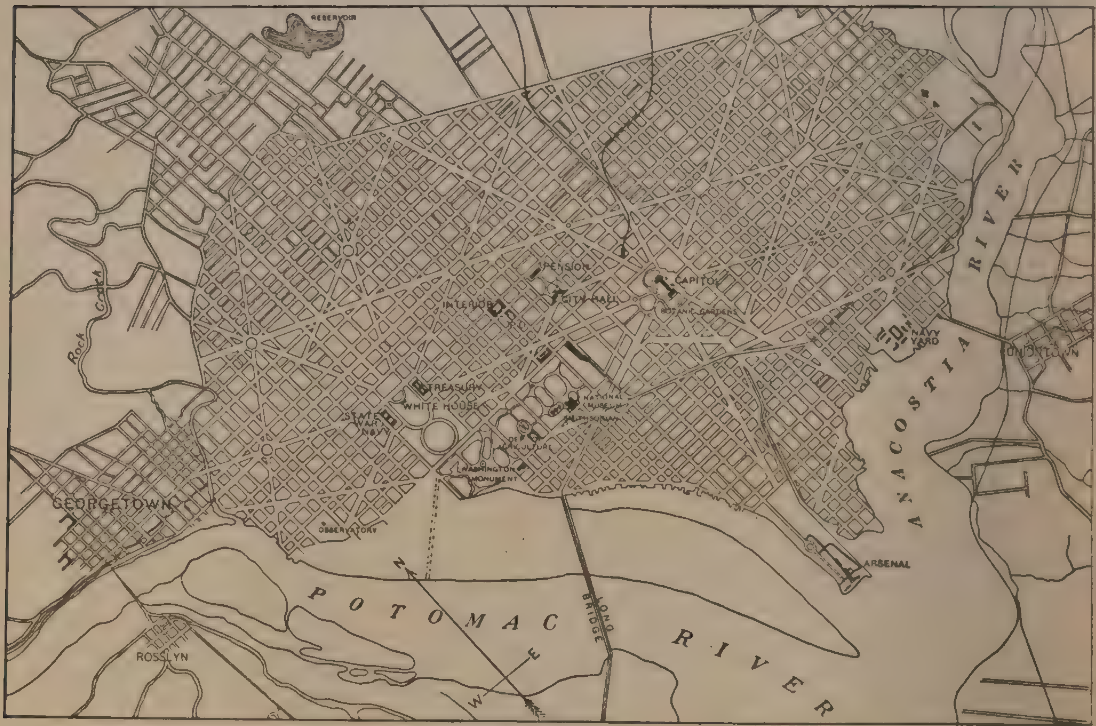
The river is crossed by three bridges,—the Long Bridge, by which the city is directly connected with the Virginia shore, the Aqueduct Bridge, so named because it formerly carried the Chesapeake and Ohio Canal, and the Chain Bridge, farther up the river.

The water supply of the District comes from the Potomac. It is taken out of the river at the head of a cataract, known as Great Falls, about 16 miles above the city. It is brought to the distributing reservoir, just above Georgetown, in an aqueduct, passing through a receiving reservoir on the way, and is thence brought to Washington and Georgetown through iron mains. No pumping is done, except to supply the suburbs on the bluffs. The water is excellent, and the supply ample. In order to give a stronger head in certain sections of the city, a tunnel has been constructed to conduct a part of the supply from the distributing reservoir to a third reservoir, north of the middle of the city. The sewer system of the city was not, like its streets, planned in advance, but was suffered to grow up, and is in consequence imperfect. There are three main outlet sewers, one emptying into the Potomac just above the Long Bridge, another near the mouth of the Anacostia, while the third, after skirting the city at the base of the bluffs, empties into the Anacostia. The houses are generally connected with the sewers. The city is fairly well lighted with gas and electric lights.

The District has an excellent common school system, modelled after that of New England; it is managed by a board of trustees appointed by the commissioners. Separate schools are maintained for white and colored pupils.

The District of Columbia is governed by three commissioners, appointed by the president of the United States. They perform the executive duties, the various departments of the civic government being apportioned among them. Legislation for the District is enacted by Congress. The District has courts of its own, the judges being appointed by the president. The people have no voice in the management of affairs. Thus is presented the singular spectacle of the capital of a great republic governed by an absolute monarchy. Still more singular, perhaps, is the fact that this is the best governed municipality in the United States. The assessed valuation of the District in 1886 was $234,039,436. Of this, nearly one-half, or $113,803,090, was non-taxable, the exemptions being as follows: property of the United States, $105,389,684; property of the District of Columbia, $2,058,772; private property, $6,354,634. The net debt was $21,279,600, and the rate of taxation $1.50 per $100. This enormous indebtedness was incurred in building up a beautiful city from a swampy waste. One-half of the interest upon it as well as one-half of the current expenses of the District, is borne by the United States. Washington is unique in the fact that it was planned and constructed solely for the purpose of serving as the seat of government. It is therefore not surprising that it is without commerce or manufactures, excepting such as are required for the support of its inhabitants.

The population of the District by the last census, taken in 1885, was 203,459 (136,271 white and 67,188 colored, the two races being in about the proportion of two to one). The population comprised within the old corporate limits of Washington was 173,606. The death-rate of the District in 1886 was—for whites 17.96, for negroes 32.35, and for all inhabitants 22.80 per thousand. The death-rate among the white population is less than in any other American city approaching Washington in size.



Plan of Washington.

The public buildings are scattered widely over the city. The Capitol (see vol. ii. p. 397) stands upon an eminence towards the eastern edge of the thickly settled portion, in the midst of extensive grounds. It consists of a central building, surmounted by a dome, and flanked by two wings, in which are the chambers of the two houses of Congress. The length of the building is 751 feet, while its breadth ranges in different parts from 121 to 324 feet. It covers nearly 3½ acres. Its extreme height, from the ground to the top of the statue of Liberty, which stands upon the dome, is 307½ feet. The material of the central building is sandstone, that of the wings marble, while the dome is of iron. The entire cost of the building has been $13,000,000. Besides the two houses of Congress, the Capitol is occupied by the United States Supreme Court and the library of Congress. For the latter a separate building is now in process of erection, upon ground just east of the Capitol.

The Treasury is situated 1½ miles west of the Capitol, at the corner of 15th Street and Pennsylvania Avenue;

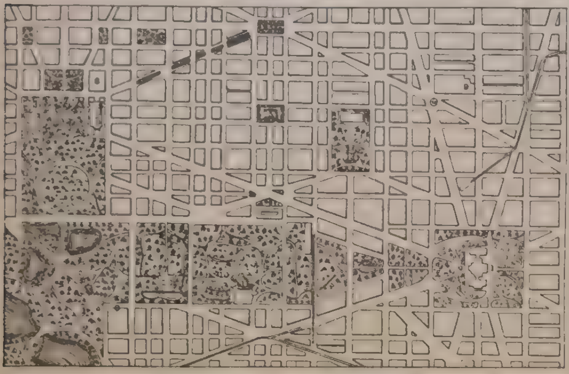
it is built mainly of granite, in the Ionic style, and measures 468 by 264 feet, with a court in the interior. It contains some 500 rooms, and cost $6,000,000. The building occupied by the state, war, and navy departments is just west of the Treasury, separated from it by the president's residence, which is known as the White House. It is built entirely of granite, is 567 feet long by 471 feet wide, and 128 feet in height, and cost $10,000,000. The interior department building is on F Street North, nearly equidistant from the Capitol and Treasury. It occupies two squares of the city, being 453 by 331 feet, with an interior court. It is simple in its proportion, and in the Doric style. It is built in part of freestone, in part of marble, while the interior is of granite. This building cost $2,700,000. The post-office department building is directly opposite the interior department, and occupies a whole square. The style is Corinthian, and the material is marble. The dimensions are 300 by 204 feet, with an interior court, and its cost was $1,700,000.



Washington—Central Portion.

1. Capitol.
2. White House.
3. State, War, and Navy Departments.
4. Treasury.
5. Interior Department.
6. Department of Justice.
7. Department of Agriculture.
8. Bureau of Engraving and Printing.
9. Government Printing Office.
10. Smithsonian Institution.
11. National Museum.
12. City Hall.

Running westward from the Capitol grounds to the river is a line of public reservations, having a breadth of four squares, from B Street North to B Street South. Within these extensive grounds are several public structures,—the botanic gardens, the buildings of the Fish Commission, the army medical museum, the national museum, the Smithsonian Institution, the department of agriculture, and the Washington monument. All these are of brick, with the exception of the Smithsonian Institution, which is of brown sandstone, and the monument, which is of marble. This is a plain obelisk, 55 feet square at the base and 555 feet in height. The White House is situated between the Treasury and the building of the state, war, and navy departments, on Pennsylvania Avenue, in the midst of ample grounds. It is of sandstone, 170 feet long by 86 feet wide. Among the other public buildings are the naval observatory, the Government printing office, the navy yard, artillery barracks, marine barracks, naval hospital, the city hall, the bureau of engraving and printing, and the pension office. Outside the former city limits are the Government asylum for the insane, the national college for the deaf and dumb, the reform school, and in the midst of a large and beautiful public park the soldier's home, a retreat for aged and disabled soldiers.

It was the design of those who laid out the city that its principal growth should be east of the Capitol. Certain causes, however, prevented this result, and sent the wealth and fashion into the northwestern quarter. This quarter contains at present more than half the population and over three-quarters of the taxable property of the District. In this section are many thousands of residences of fine and varied architecture, the display of which has been much encouraged by the freedom of the building regulations.

Washington is one of the most cosmopolitan of cities. Its population is not only drawn from all parts of the United States, but every civilized nation has its representatives there. Its social life is characterized by a degree of variety and freedom rarely enjoyed elsewhere. It has become in recent years the American centre of scientific thought, and is rapidly gathering men of letters.

Washington was selected as the site for the federal capital in 1790. The States of Maryland and Virginia had ceded to the general Government a tract of land 10 miles square, lying on both sides of the Potomac, for that purpose. The Virginia portion was subsequently re-ceded to that State. In 1790 Georgetown was a city of considerable importance, but upon the site of Washington there were very few settlers. The plan of the city was drawn by Major l'Enfant, and the city laid out in accordance therewith by Andrew Ellicott. At that time the greater part of the site lying west of the Capitol was a morass, well-nigh impassable. The machinery of the government was moved to Washington in 1800, when it was "a backwoods settlement in the wilderness." It existed principally upon paper, and the magnificence of the plan only served to emphasize the poverty of the execution. In 1814, during the second war with Great Britain, it was captured by the British troops, and the Capitol, together with most of the other public buildings, was burned. In 1839 it was described as a "large straggling village reared in a drained swamp." Indeed, in 1871, although it had attained to considerable size, it was exceedingly backward in all municipal improvements. The public buildings and grounds were neglected. The streets were deep in mud, or clouded with dust; the unbuilt portions were morasses; and the sewerage was worse than useless. In that year Congress abolished the charters of the two cities, and instituted a form of territorial government, with a governor and a legislative assembly. The matter of municipal improvement was placed in the hands of a board of public works, with authority to carry out a comprehensive scheme. The work was commenced and pushed forward with the greatest energy, and almost fabulous results were achieved. In a very few years the appearance of the city was revolutionized. The cost of these improvements, was, however, enormous, and it was increased greatly by the rapidity with which the work was done. Much of it, too, was badly executed, so that it has been necessary to replace it. But, in spite of these drawbacks, the fact that Washington is one of the most beautiful and comfortable cities in the world is principally due to the first governor of the District and his board of public works. This government lived too fast to live long. In 1874 Congress abolished the territorial form, and established the present government by three commissioners.

The following figures illustrate the growth of the District in population: 1800, 14,093; 1820, 33,039; 1840, 43,712; 1860, 75,080; 1870, 131,700; 1880, 177,624; 1885, 203,459. Washington had 109,199 inhabitants in 1870, and 147,293 in 1880. (H. G*.)

Plate IX.

WASHINGTON, a Territory of the United States, is the extreme northwestern political subdivision of the Union (except the detached Alaska), and is bounded on the N. by the Canadian province of British Columbia, on the E. by Idaho Territory, on the S. by Oregon, and on the W. by the Pacific Ocean. It lies between 45° 40′ and 49° 0′ N. lat. and 117° 0′ and 124° 44′ W., long., and has a total land area within its boundaries of 66,880 square miles and a water area of 3114 square miles; its average length from east to west is 330 miles and from north to south is 220 miles. The Territory is divided by the Cascade Mountains into two unequal sections, which have very different climatic and physical characteristics and commercial and business interests. The climate is very mild, on account of the warm oceanic current from Japan which flows south along the coast. The moisture-bearing winds moving inland from the ocean are chilled against the Cascade Mountains, and cause the western section of the Territory to have a very heavy annual rainfall (about 53 inches), which is quite evenly distributed throughout the year. The summers are cool and pleasant and the winters mild; flowers bloom in the open air every month in the year, and the nights are always cool and refreshing. The climate in the western section is similar to that of Scotland. That of the eastern section is remarkable for clearness and brightness; it is hot and dry in summer, and has a brief and severe winter. The climate is tempered by a remarkable balmy wind, called the Chinook wind, coming over the mountains from the great Japanese current of the Pacific. In the summer it is a cool wind tempering the heat, and in the winter it is a warm wind, before which snow and ice disappear with marvellous rapidity.

The Cascade range is the local name of the extension through the Territory of the Sierra Nevada, the great and sharply defined mountain chain which extends at a distance from shore of about 100 miles through the Pacific States and Territories (see vol. xxiii. p. 851). To the north of the Columbia river the range widens out considerably into a region of high grassy mountain plateaus, of deep cañons, heavily timbered slopes, and high peaks of volcanic origin, furnishing mountain scenery of indescribable grandeur. The western slopes are covered with magnificent forests, principally of fir, the trees growing to an immense size. The mountain plateaus are from 3000 to 5000 feet in elevation, untimbered and covered with excellent grass, furnishing a large extent of valuable pasture-land. On the eastern slope the forests are more open, and consist principally of blue and yellow pine, tamarack, fir, and white cedar. The Northern Pacific Railroad reaches the sea by two routes, one of which goes down the Columbia river, and the other crosses the Cascade range by the Yakima Pass in 47° 20′ N. lat.; this pass has an elevation of 3600 feet, and is in a region of beautiful deeply-embosomed lakes, the high cliff-like banks of which are crowned with splendid evergreen forests. To the north of the Yakima Pass the range becomes higher, and more rough and rugged than it is farther south. There seems to have been a volcanic centre between the Yakima and Wenatchee and about midway between the upper Yakima lakes and the Columbia, the highest peak of which is known as Mount Stuart, from which poured a grand flood of lava to the east and south, forming the elevated range between the Yakima and Wenatchee known as the Wenatchee Mountains, and crossing the present channel of the Columbia and forming Badger Mountain on the east. To the north of the 48th parallel, which is about the line of the Spokane river and the westward-flowing portion of the upper Columbia, the country changes, becoming more independent in its mountain formations, and the eastern jutting ranges of the Cascades meet and join with the earlier rock materials of the western spurs of the Rocky Mountains. Here the great interior basin may be considered as ending, for to the north the Rocky and Cascade ranges approach and are blended in inextricable confusion. The principal rivers having their sources in the Cascade Mountains on the west are the Nooksack, Skagit, Steilaguamish, Snohomish, Puyallup, and Nisqually flowing into Puget Sound, the Chehalis flowing into Gray's Harbor, and the Cowlitz and Lewis rivers flowing into the Columbia; while on the east are the Methow, Chelan, Wenatchee, Yakima, and Klickitat, flowing into the Columbia. The mountains are well stocked with large game, as deer, bear, mountain sheep, mountain goats, wolves, panthers, foxes, etc., the valleys, plateaus, and lakes with feathered game, and the streams and lakes with trout and salmon.

The western section of the territory lying between the Cascades and the ocean is the smaller of the two, and is covered with timber throughout nearly its entire extent. The principal natural feature is Puget sound —one of the most beautiful sheets of salt water in the world, if not indeed *the* most beautiful. It is an arm of the sea joining the waters of the Gulf of Georgia and Strait of Juan de Fuca, and stretching about a hundred miles to the south into the heart of the country; it has a great number of bays, coves, inlets, and channels branching off from the main sound, altogether forming a collection of harbors unsurpassed in the world. The total area of the Sound, is about 2000 square miles, with a shore-line of about 1600 miles. The water is very deep, in places more than 800 feet, the ordinary depth in the inlets and channels being from 300 to 600 feet. These depths in some places continue right up to the shore, so that vessels of the deepest draught could go and tie up to the trees on the banks as to a wharf. The tides in Puget Sound vary ordinarily from about 9 feet at Port Townsend to 15 feet or more at Olympia and the remote inlets. Along the shores, and for many miles back, the country is covered with the densest growth of very fine timber. The region of the Olympic Mountains lying between Puget Sound and the Pacific has never been explored to any extent, owing to the enormous difficulties of penetrating the forests, which, besides the standing trees, consist of masses of fallen timber and undergrowth. No rivers or creeks navigable for canoes penetrate any distance into it. There is no doubt that Puget Sound once extended much farther south, and occupied the Willamette valley of Oregon. Its retrogression has left large areas of low-lying land bordering the Sound and between it and the Columbia, which, when brought under cultivation, are found to be remarkably fertile. There are large areas of these low-lying lands covered with water at the highest tides which could be easily reclaimed by diking; about 30,000 acres have been so reclaimed, and it is estimated that 150,000 acres besides can be thus improved. There are no good harbors along the Pacific coast of the Territory; but on the Straits of Juan de Fuca several fine ones exist. Western Washington is specially adapted to raising all the grasses, oats, hops, the root-crops, and fruits; whatever requires great heat does not ripen well.

Eastern Washington Territory differs in a very marked manner and in almost every material respect from the western section. South of the 48th parallel and east of the Cascades it is essentially a prairie country, which owes its origin to the great lava flow that covered eastern Oregon and northern California. This lava has disintegrated in the course of ages, and produced a soil which is unsurpassed in the world for richness. The region lying between the Blue Mountains and the Snake river, known as the Walla Walla country, and that between the Snake and the Spokane, known as the Palouse and Spokane countries, are noted for their fertility. This is also the case with the regions along the eastern foot-hills of the Cascades known generally as the Yakima and Kittitass countries. In these regions there is sufficient rainfall to enable the agriculturist to raise almost every product of the temperate zone of the finest quality and in the greatest abundance. Besides the cereals, such as wheat, oats, barley, flax, etc., there are grown grapes, apples, cherries, peaches, prunes, potatoes, both white and sweet, tobacco, cotton, broom corn, sorghum, peanuts, egg plants, etc. Over a large part of this eastern section, however, the rainfall is not sufficient, and irrigation must be resorted to. With irrigation properly conducted it is safe to say that nearly every foot of land now classed as desert will be found to be as productive as the regions more favored by rain.

That part of eastern Washington Territory north of the Columbia and Spokane rivers is a region of low-timbered mountains and fertile valleys. This is mostly given up to the Indians, there being the two large reservations called the Columbia and Colville reservations stretching from the Cascade Mountains eastward to the southward-flowing portion of the Columbia, and embracing 7880 square miles of land. North of the Spokane river is the Colville country, which is open to settlement, and in which are much good land and large quantities of valuable timber.

The most important feature of eastern Washington is the Columbia river, which enters the Territory from British Columbia at about 117° 30′ W. long., and pursues nearly a southerly course to the "Big Bend," a distance of 110 miles, where it takes a westerly course which it keeps for 93 miles until it receives the waters of the Okinakane, where it changes its course again to the south, keeping it for 224 miles, until it unites with its greatest tributary, the Snake river; from this point it keeps a westerly course, breaking through the Cascades, and entering the Pacific in lat. 46° 15′. It forms the boundary between Washington Territory and Oregon for this latter part of its course. The lower portion of the Columbia is described under OREGON (*q.v.*). The upper part may be briefly described as a deeply cañoned river with numerous rapids and falls, which make it unnavigable and in all probability incapable of improvement. The Kettle Falls, near the northern boundary, are the most marked on the river, being about 25 feet at low water. Here each year the Indians from all directions gather on neutral ground to take salmon for their next year's subsistence. A salmon chief is elected, whose duties are to keep order and to divide equitably all the fish taken. The fish are taken in baskets as they try to jump the falls, those that fail falling back into the baskets. That part of the Columbia from the northern boundary-line to the "Big Bend" is the most beautiful portion of the river within the Territory, except where it breaks through the Cascades. Throughout this portion there is considerable bottom-land, and this and the neighboring hills and mountains are well covered with fine open timber, with charming little grassy prairies scattered here and there. Below the Big Bend the cañon of the Columbia becomes more prominent, the timber recedes from the banks, and the channel narrows between basalt rocks, and in places is highly dangerous to anyone who entrusts himself upon the waters. The general depth of the cañon is about 2000 feet. Much gold is found in the sand bars and low terraces along the river.

The principal tributaries of the Columbia within the Territory are Clarke's Fork, the outlet of Lake Pend d'Oreille, an unnavigable stream flowing through a deep cañon, which enters the Columbia just above the northern boundary of the Territory. The Spokane river, one of the most important tributaries, is the outlet of Lake Cœur d'Alene, which drains a large extent of the Bitter Root Mountains. The Spokane, from the lake to Spokane Falls, a distance of about 30 miles, flows just below the level of a lovely prairie country; at the falls the river takes a plunge of 156 feet, and from there to the Columbia it flows through a deep cañon. These falls of the Spokane furnish one of the finest, most accessible, and most easily controlled water-powers in the world, and already they are utilized to a considerable extent for manufacturing purposes. The Okinakane is the next important tributary; it rises in British Columbia and flows southward through Lakes Okinakane and Osoyoos, and enters the Territory in 119° 30′ W. long. Its course lies through a rich and inviting country. At its mouth was one of the most important of the old Hudson's Bay Company's trading posts. The Methow river, Lake Chelan and its outlet, and the Wenatchee are rivers of considerable magnitude, draining the eastern slopes of the Cascades. They are in a mountainous country presenting few attractions to the settler. The Yakima, which also comes from the Cascades, is of far greater importance, as about its headwaters is a large amount of fine agricultural land, and the river itself and its tributaries will ultimately furnish the water for irrigating an enormous extent of very fine land now virtually desert. Already large irrigating canals, having a total length of 325 miles, are projected, and work on them has been commenced.

The largest tributary of the Columbia, the Snake, joins it about 8 miles below the mouth of the Yakima. The Snake is navigable for the whole 150 miles of its course through the Territory, but has some difficult rapids. It flows through a cañon 1000 to 2000 feet deep, which it has cut for itself through the lava deposits.

An area nearly encircled by the Columbia, below the Big Bend, and the Snake, in the last 50 miles of its course, is known as the Great Plain of the Columbia. Its southern part is an alkaline nearly waterless desert, the principal vegetation being sage brush; the northern part is somewhat more elevated, and is for the most part a rich rolling grassy country intersected here and there by *coules*, or deep and almost vertical cuts, through the basalt rock underlying the soil. They indicate the former presence of large streams of water.

Forests.—Very valuable forests exist in every part of western Washington and in the northern part of eastern Washington. The sawmills on Puget Sound have a capacity of 350,000,000 feet per year, and the total capacity of the mills of the Territory is over 650,000,000 feet per year. The principal timber is yellow and red fir, ordinarily known as "Oregon pine,"[1] which constitutes the bulk of the forests; white and red cedar, spruce, and larch also abound. White pine of magnificent size grows on the upper benches of the Cascade Mountains; white fir and hemlock are also found. Alder, maple, ash, oak, and cottonwood occur in abundance on the bottom-lands of western Washington, but are not equal to timber of the same names in the east. Bull pine, yellow pine, and tamarack grow on the eastern slopes of the Cascade range, and constitute the bulk of the forests of eastern Washington. They make a fair quality of lumber, but greatly inferior to the products of the western slopes and the Pacific coast regions.

Fisheries.—The salmon fisheries of the Columbia river, Shoalwater Bay, Gray's Harbor, and Puget Sound form one of the leading industries of the Territory. The preservation of salmon in cans was commenced in 1866 on the Columbia river, and the business rapidly increased, so that now the annual value of the pack is from 2 to 2½ million dollars.

Mines and Mining.—The mineral resources of the Territory are very great upon both sides of the Cascade Mountains. There are large tracts of valuable coal-lands between Puget Sound and the Cascades, stretching all the way from Bellingham Bay on the north to the Chehalis valley on the south. The veins at present worked vary from 5 to 12 feet in thickness, and in quality from lignite to bituminous coal, some of which produces gas and coke of superior excellence. Mines are also worked on the eastern slope of the Cascades about the head of the Yakima river. The present known area of coal-lands in the Territory is about 180,000 acres, and the total shipments for the year ending June 30, 1887, amounted to 525,705 tons. The supply of coal for the Pacific coast is mainly drawn from the beds in Washington Territory and their continuation in British Columbia.

There are large deposits of valuable iron ore in the western part of the Territory and in the Snoqualmie Pass. Brown hæmatite iron ore is found in Skagit county, magnetic ore in King county, and bog iron ore of the best quality in several counties, notably Jefferson, King, and Pierce; but these deposits have not yet been worked to any great extent. There can be no question, however, that the existence of coal, iron, and timber in the near vicinity of Puget Sound must make this a great manufacturing and shipbuilding centre. Limestone is found in great abundance on San Juan Island, in the Puyallup valley, and in the northeastern part of the Territory. Copper and lead are found in different localities.

The northern part of eastern Washington abounds in mines of the precious metals, and these are now being worked on quite an extensive scale. In the Colville district (between the Columbia, Clarke's Fork, and Spokane rivers) the prevailing country rock is limestone, and the prevailing mineral is argentiferous galena; at some points gray copper ore is found carrying both silver and lead, and in others silver chlorides are found. The development of these mines has been delayed by lack of railway facilities, but this will be remedied in a short time by lines now projected and incorporated.

The Kettle river district lies to the west of the Columbia, and in regions about the headwaters of the river. The mines are very varied in their character, comprising placer gold, gold quartz, copper, and galena with carbonates. Some of the placer mines have yielded heavily, the gold being coarse and obtained by ground sluicing. Very valuable quartz ledges, assaying 80 to 2000 ounces of gold per ton have been discovered in a formation of granite and slate.

The Okinakane district comprises the mines in the vicinity of the Okinakane, Salmon, and the Similkameen rivers and Osoyoos lake. Here the formation is granite, syenite, and porphyry, and the ores are galena, gray copper, and quartz, carrying sulphurets and native silver.

The city of Spokane Falls, on the Northern Pacific Railroad, is the distributing point for all these mines, as well as for the Cœur d'Alene mines in northern Idaho.

Shipbuilding.—Shipyards exist at Seattle and Tacoma, and at other points on Puget Sound, at Gray's Harbor and Shoalwater Bay, and on the Columbia river. The vessels constructed are mainly schooners for the lumber-carrying trade; many of them also are provided with auxiliary steam-power. All raw materials for their construction are found in the vicinity. The yellow fir of the Northern Pacific ranks next to oak for strength and durability, and constitutes excellent material for shipbuilding. Vessels of 4854 tons were built during 1886, and the industry is rapidly growing.

---

[1] [The name "Oregon pine" is popularly given to the Douglas fir, *Pseudotsuga Douglasii*, called yellow and red fir. It is sometimes found ten feet in diameter and 300 feet in height. See Sargent's *Report*, vol. ix. in 10*th U. S. Census*.—AM. ED.]

Commerce.—The principal articles of export are lumber, coal, wheat, and salmon, and their annual value is from 8 to 10 millions of dollars. In the year from July, 1886, to June, 1887, the total entrances at Puget Sound were 994 vessels (539,597 tons) and the clearances 988 (514,441 tons).

Railways.—Washington Territory was the last of the political subdivisions of the United States to be reached by railroads. In 1883 the Northern Pacific was completed and direct rail connection secured with the east.

Education.—There are about a thousand common schools in the Territory, under the supervision of a superintendent of public instruction and a board of education of three persons, all of whom are appointed by the governor. In each county, county superintendents and a board of county examiners visit the schools and report to the superintendent of public instruction. There is held each year a territorial teachers' institute, and local teachers' institutes are also held in different sections. These common schools are supported by county taxes and by certain criminal fines. Special taxes are also permitted in counties under certain conditions. There are at present about 65,000 children under instruction, at a cost of about $500,000 per annum.

The general Government has set aside for educational purposes one-eighteenth of all the land in the Territory, comprising about 2½ million acres. This land, however, does not become available until the Territory becomes a State. All children must attend school at least three months in the year.

There is a university at Seattle, supported by large annual appropriations of the legislature. It has four departments at present: literature, science, and the arts; law; medicine; and military instruction. There are also twenty-four higher institutions of learning scattered throughout the Territory, consisting of colleges, seminaries, and academies, most of which are under sectarian control, and some of which have already a liberal endowment.

Churches.—All the leading Christian sects are well represented in the Territory, their membership and value of church property being about in the order given below: Methodist Episcopal, Roman Catholic, Protestant Episcopal, Congregational, Baptist, Presbyterian, Christian, Lutheran, German Reformed, and Unitarian.

Government.—The administrative affairs of the Territory are in the hands of a governor, secretary, and chief justice, all appointed by the president of the United States, and a treasurer and comptroller and an upper and lower legislative house elected by the people. The Territory is represented[1] in Congress by a delegate also elected by the people.

Population.—The total population, 75,116 in 1880, was 143,669 (84,470 males, 59,199 females) according to the census taken in 1886 and 1887, classified as follows: whites, 137,430; blacks, 254; mulattoes, 69; Chinese, 2584; Indian half-breeds, 3288; and Kanakas, 44. In addition to these there are about 11,000 Indians. The total population is now (1888) about 175,000. The capital is Olympia, and the chief city Seattle, both on Puget Sound.

Banks.—There are in the Territory 18 national banks, with a capital of $1,430,000, 5 territorial banks, with a capital of $355,000, and also a number of private banks.

History.—The first event in history relating to Washington Territory was the discovery, in 1592, of the Strait of Juan de Fuca by an old Greek pilot of that name in the service of Spain. In 1775 Captain Hecata, a Spanish navigator, discovered the mouth of the Columbia, but was unable to enter the river. Captain Kendrick, an American navigator, in 1789 sailed into the Strait of Fuca and through the Gulf of Georgia and Queen Charlotte Sound to the Pacific, and was the first to clearly make known the character of these inland waters. On the 11th of May, 1792, Captain Gray, of the American ship "Columbia," sailed into and explored for about 15 miles the great river to which he gave the name of his ship. This first entrance into the Columbia river gave the United States their principal claim to the territory drained by the river, and is thus a very important episode in the history of the Oregon region, which formerly comprised the present State of Oregon and the Territories of Washington and Idaho. In October of the same year (1792) an Englishman, Lieutenant Broughton, sailed up and examined the Columbia for about 100 miles from its mouth. The coast soon became quite well known, and the government of the United States fitted out a number of expeditions to obtain a knowledge of the interior. The most important of these was that of Lewis and Clarke, who were directed to ascend the Missouri, cross the Rocky Mountains, and trace the Columbia from its sources to the sea. They began the ascent of the Missouri in 1804, and spent the winter of 1804–5 at Fort Mandan. In the next season, after incredible hardships and great sufferings, they crossed the Rocky Mountains, and reached the Clearwater river. Here they made boats, and proceeded down it, the Snake river, and the main Columbia, reaching the Pacific in December, 1805. They returned by nearly the same route.

The next important era in the history of the Territory was the attempt of J. J. Astor to establish a fur-trading empire on the Columbia and its tributary lands and streams. Two expeditions were sent out in 1810 for this purpose, one by land and one by sea. The latter reached the Columbia in 1811, and established a trading post at Astoria near the mouth of the river. The land expedition reached this post in 1812. In the meantime, in hopes of forestalling Astor's expeditions, the Northwest Fur Company sent a party in 1810 to cross the mountains and reach the mouth of the Columbia before them. This expedition experienced great difficulty in crossing the mountains in 52° N. lat., but in the spring of 1811 they reached the Columbia, and went down to its mouth, where they found Astor's sea party already established. This Northwest Fur Company's expedition was the first to navigate the upper Columbia, or to traverse any part of the country drained by it. In 1813 the fortunes of war compelled the transfer of the Astor Fur Company to the Northwest Fur Company. Henceforward for many years the history of the Territory is the history of the operations of the great Northwest and Hudson's Bay Companies, and of the effort of private parties to get a share in the profits of the fur trade. A number of trading posts were built, and exploring and trading expeditions sent into all parts of the country. Missionaries began to arrive, and emigrants to drift in by sea and land.

During all the years in which this region was first being explored and settled, a dispute had been going on between the United States and Great Britain in regard to its ownership, which at different times waxed so fierce as to threaten war. Finally an arrangement was arrived at, and in 1846 the treaty was signed fixing the boundary-line at the 49th parallel. The Territory of Oregon (comprising Washington, Idaho, and Oregon) was formed in 1848, and General Joseph Lane, the first Territorial governor, arrived in 1849, after which United States courts were established. The present territory of Washington was established in 1853, and its first governor was Isaac I. Stevens.

The settlement of the Territory has been slow, on account of its remoteness and the fact that it has had no great mining excitement to attract adventurous settlers. Since the advent of railroads, however, its development has been rapid. (T. W. S.)

WASHINGTON, GEORGE (1732–1799), the first president of the United States, was born in Westmoreland county, Virginia, February 22 (Old Style,[2] Feb. 11), 1732. One lawless genealogist has traced his ancestry back to Odin. Another genealogy, since given up with much regret, connected the family with the Washingtons of Northumberland or Durham, England. The ancestry of Washington can be traced no farther back than his great-grandfather, John Washington, who settled in Virginia about 1657. His eldest son, Lawrence, had three children—John, Augustine, and Mildred. Augustine Washington married twice. By the first marriage with Jane Butler, there were four children, two of whom, Lawrence and Augustine, grew to manhood. By the second marriage, with Mary Ball, in 1730, there were six children—George, Betty, Samuel, John, Augustine, Charles, and Mildred. The father died when George was but twelve years old; Lawrence inherited the estate now known as Mount Vernon, and George his father's usual residence, nearly opposite Fredericksburg.

Very little is known of Washington's early life, probably because there was little unusual to tell. The story of the hatchet and the cherry tree and similar tales, are quite apocryphal, having been coined by Washington's most popular biographer, Weems. The boy's life was not different from that common to Virginia families in easy circumstances; hunting, fishing, plantation affairs, and a little reading made up its substance. His education was but elementary and very defective, except in mathematics, in which he was largely self taught. Sparks has "edited" the spelling, grammar, and rhetoric of Washington's *Writings* to such an extent as to destroy their value as evidence. About 1748 we begin to know something of Washington's life. He was then at Mount Vernon with his half-brother Lawrence, who was his guardian. Lawrence was the son-in-law of his neighbor Lord Fairfax, with whom he had served at Carthagena, and had made the acquaintance of Admiral Vernon, from whom Mount Vernon was named. A commission as midshipman was obtained for George through the Admiral, but the opposition of the boy's mother put an end to the scheme. As a substitute, the appointment as surveyor of the enormous Fairfax property was given to Washington at the age of sixteen; and the next three years of his life were spent in this service. He always retained a disposition to speculate in Western lands; many of his later investments were of this kind, and they are treated in Butterfield's *Washington-Crawford Letters.* He seems already to have impressed others with a belief in his force of mind and character, for at the age of nineteen, when the first indications of the "French and Indian war" appeared, he was appointed adjutant of the Virginia troops, with the rank of major; on the death of his half-brother Lawrence in the following year he was executor under the will, and residuary heir of Mount Vernon; and in 1753, when he had barely attained his majority, the young man was made commander of the northern military district of Virginia by the new lieutenant-governor, Dinwiddie. It is at this point in his career that Washington appears in Thackeray's *Virginians*, but the portrait there drawn of a "shrewd young man" on the lookout for a rich wife is not accepted as lifelike by Americans.

---

[1] [Territorial delegates in Congress have no vote, but enjoy the other privileges of the House.—AM. ED.]

[2] [Old Style includes the year 1731.—AM. ED.]

At the outbreak of the French and Indian war in 1753–54, Washington was the agent sent by Governor Dinwiddie to warn the French away from their new forts in western Pennsylvania; the command of the Virginia troops who began hostilities fell to him, and his vigorous defence of Fort Necessity[1] (see UNITED STATES, vol. xxiii. p. 782) made him so prominent a figure that in 1755, at the age of twenty-three, he was commissioned commander-in-chief of all the Virginia forces. He served in Braddock's campaign, and in the final defeat showed for the first time that fiery energy which always lay hidden beneath his calm and unruffled exterior. He ranged the whole field on horseback, making himself the most conspicuous mark for Indian bullets, and, in spite of what he called the "dastardly behavior" of the regular troops, brought the little remnant of his Virginians out of action in fair order. In spite of this reckless exposure he was one of the few unwounded officers. For a year or two his task was that of "defending a frontier of more than 350 miles with 700 men;" but in 1758 he had the pleasure of commanding the advance guard of the expedition which captured Fort Du Quesne and renamed it Fort Pitt. The war in Virginia being then at an end, he resigned his post, married Mrs. Custis, a widow, and settled at Mount Vernon.

Washington's life for the next twenty years was merely that of a typical Virginia planter, a consistent member[2] of the Established (Episcopal) Church, a large slaveholder, a strict but considerate master, and a widely trusted man of affairs. His extraordinary escape in Braddock's defeat led a colonial minister to declare in a sermon his belief that the young man had been preserved to be "the saviour of his country."[3] If there was any such impression it soon died away, and Washington gave none of his associates reason to consider him an uncommonly endowed man. His marriage had brought him an increase of about $100,000 in his estate; and his diaries show comparatively little reading, a minutely methodical conduct of business, a wide acquaintance with the leading men of the country, but no strong indications of what is usually considered to be "greatness." As in the case of Lincoln, he was educated into greatness by the increasing weight of his responsibilities and the manner in which he met them. Like others of the dominant caste in Virginia, he was repeatedly elected to the legislature, but he is not known to have made any set speeches in that body, or to have said anything beyond a statement of his opinion and the reasons for it. That he thought a great deal, and took full advantage of his legislative experiences as a political education, is shown by his letter of April 5, 1769, to his neighbor George Mason, communicating the Philadelphia non-importation resolutions, which had just reached him. He considers briefly the best peaceable means of resistance to the policy of the ministry, but even at that early date faces frankly and fully the probable final necessity of resisting by force, and endorses it. Without speech-making, he took a prominent part in struggles of his legislature against Governor Dunmore, and his position was always a radical one. He even opposed petitions to the king and parliament, on the ground that the question had been put by the ministry on the basis of right, not of expediency, that the ministry could not abandon the right and the colonists could not admit it, and that petitions must be, as they had been, rejected. "Shall we," says he in a letter, "after this whine and cry for relief?" In 1774 the Virginia Convention, appointing seven of its members as delegates to the Continental Congress, named Washington as one of them; and with this appointment his national career begins.

Washington's letters during his service in Congress show that he was under no delusions as to the outcome of the taxation struggle, and that he expected war. In one letter he says that if the ministerial policy is persisted in "more blood will be shed than history has ever yet furnished instances of in the annals of North America." His associates in Congress recognized his military ability at once, and most of the details of work looking towards preparations for armed resistance were by common consent left to him. Even in the intervals of his Congressional service he was occupied in urging on the formation, equipment, and training of Virginia troops, and it was generally understood that, in case of war, Virginia would expect him to act as her commander-in-chief. History was not to be cheated in that fashion. The two most powerful colonies were Virginia and Massachusetts. War began in Massachusetts; New England troops poured in almost spontaneously; it was necessary to ensure the support of the colonies to the southward; and the Virginia colonel who was at the head of all the military committees was just the man whom the New England delegates desired. When Congress, after the fights at Lexington and Concord, resolved to put the colonies into a state of defence, the first practical step was the unanimous selection, on motion of John Adams of Massachusetts, of Washington as commander-in-chief of the armed forces of the United Colonies. Refusing any salary, he accepted the position, asking "every gentleman in the room," however, to remember his declaration that he did not believe himself to be equal to the command, and that he accepted it only as a duty made imperative by the unanimity of the call. He reiterated this belief in private letters even to his wife; and there seems to be no doubt that, to the day of his death, he was the most determined skeptic as to his fitness for the positions to which he was called in succession. He was commissioned June 19, 1775, and reached Cambridge, Mass., July 2, taking command of the levies there assembled for action against the

British garrison of Boston. The battle of Bunker Hill had already taken place, and Washington's work until the following spring was to bring about some semblance of military discipline, to obtain ammunition and military stores, to correspond with Congress and the colonial governors, to guide military operations in the widely separated parts of a great continent, to create a military system and organization for a people who were entirely unaccustomed to such a thing and impatient under it, and to bend the course of events steadily towards driving the British out of Boston. It is not easy to see how Washington survived the year 1775; the colonial poverty, the exasperating annoyances, the selfishness or stupidity which cropped out again and again from the most patriotic of his coadjutors, were enough to have broken down most men. They completed his training. The change in this one winter is very evident. If he was not a great man when he went to Cambridge, he was a general and a statesman in the best sense when he drove the British out of Boston in March, 1776. From that time until his death he was the foremost man of the continent.

The military operations of the remainder of the war are given elsewhere (see UNITED STATES, vol. xxiii. pp. 791–93) Washington's retreat through the Jerseys; the manner in which he turned and struck his pursuers at Trenton and Princeton, and then established himself at Morristown so as to make the way to Philadelphia impassable; the vigor with which he handled his army at Chadd's Ford and Germantown; the persistence with which he held the strategic position of Valley Forge through the dreadful winter of 1777–78, in spite of the misery of his men, the clamors of the people, and the impotence of the fugitive Congress,—all went to show that the fibre of his public character had been hardened to its permanent quality. The Valley Forge winter was said to be "the time that tried men's souls;" Washington's had no need to fear the test. It was a serious addition to his burdens that the spirit which culminated in Benedict Arnold chose this moment to make its appearance. Many of the American officers had been affronted by the close personal friendship which had sprung up between La Fayette and Washington, and by the diplomatic deference which the commander-in-chief felt compelled to show to other foreign officers. Some of the latter showed no gratitude. The name of one of them [Thomas] Conway, an Irish soldier of fortune from the French service, is attached to what was called "Conway's Cabal." He formed a scheme for replacing Washington in the command by Gates, who had just succeeded in forcing Burgoyne to surrender at Saratoga; and a number of officers and men in civil life were mixed up in it. The methods employed were the lowest forms of anonymous slander, and at the first breath of exposure every one concerned hurried to cover up his part in it, leaving Conway to shoulder all the responsibility. The treaty of 1778 with France put an end to every such plan. It was a flat absurdity to expect foreign nations to deal with a second-rate man as commander-in-chief while Washington was in existence, and he seems to have had no more trouble of this kind. The prompt and vigorous pursuit of Clinton across the Jerseys towards New York, and the battle of Monmouth, in which the plan of battle was thwarted by Charles Lee, another of the foreign officers, closed the direct military record of Washington until the end of the war. The enemy confined their movements to other parts of the continent, and Washington did little more than watch their headquarters in New York city. It was more than appropriate, however, that he who had been the mainspring of the war, and had borne far more than his share of its burdens and discouragements, should end it with the campaign of Yorktown, conceived by himself, and the surrender of Cornwallis. The war was then really over, but the commander-in-chief retained his commission until December 28, 1783, when he returned it to Congress, then in session at Annapolis, Md., and retired to Mount Vernon.

By this time the canonization of Washington had fairly begun. He occupied such a position in the American political system as no man could possibly hold again. He had become a political element, quite apart from the Union, the States, or the people of either. In a country where communication was still slow and difficult, the general knowledge that Washington favored anything superseded argument and the necessity of information with very many men. His constant correspondence with the governors of the States gave him a quasi-paternal attitude towards government in general. On resigning his commission, for example, he was able to do what no other man could have done with propriety or safety: he addressed a circular letter to the governors of the States pointing out changes in the existing form of government which he believed to be necessary. His refusal to accept a salary, as general or as president, would have been taken as affectation or impertinence in any one else; it seemed natural and proper enough in the case of Washington, but it was his peculiar privilege. It is possible that he might have had a crown if he had even been willing. The army, at the end of the war, was justly dissatisfied with its treatment. The officers were called to meet at Newburgh, and it was the avowed purpose of the leaders of the movement that the army should march westward, appropriate vacant lands, leave Congress to negotiate for peace without an army, and "mock at their calamity and laugh when their fear cometh." It was the less publicly avowed purpose to make their commander-in-chief king, if he could be persuaded to aid in establishing a monarchy. Washington put a summary stop to the whole proceeding. Their letter[1] to him detailed the weakness of a republican form of government as they had experienced it, their desire for "a mixed government," with him at its head, and their belief that "the title of king" would be objectionable to few and of material advantage to the country. His reply was peremptory, and even angry. He stated in plain terms his abhorrence of the proposal; he was at a loss to conceive what part of his conduct could have encouraged their address; they could not have found "a person to whom their schemes were more disagreeable;" and he threatened them with exposure unless the affair was stopped at once. His influence, and that alone, secured the quiet disbanding of the discontented army. His influence was as powerful after he had retired to Mount Vernon as before his resignation. He was in constant correspondence with public men in every part of the country. He received from them such a store of suggestions as came to no other man, digested it, and was able from it to speak with what seemed infallible wisdom. In the midst of his voluminous correspondence, the minute details in his diaries of tree-planting and rotation of crops, and his increasing reading on the political side of history, he found time for a stream of visitors. Among these, in March, 1785, were the commissioners from Virginia and Maryland, who met at Alexandria to form a commercial code for Chesapeake Bay, and made an opportunity to visit Mount Vernon. From that moment the current of events, leading into the Annapolis convention of 1786 and the final convention[2] of the next year, show Washington's close supervision at every point.

When the Federal convention met at Philadelphia in May, 1787, to frame the present constitution, he was present as a delegate from Virginia, though much against his will; and a unanimous vote at once made him its presiding officer. He took no part in the debates, however, beyond such suggestive hints as his proposal to amend a restriction of the standing army to 5000 men by forbidding any enemy to invade the United States with more than 3000. He approved the constitution which was decided upon, believing, as he said, "that it was the best constitution which could be obtained at that epoch, and that this or a dissolution awaits our choice, and is the only alternative." All his influence was given to secure its ratification, and his influence was probably decisive. When it had been ratified, and the time came to elect a president, there was no more hesitation than if the country had been a theocracy. The office of president had been "cut to fit the measure of George Washington," and no one thought of any other person for it. The unanimous vote of the electors made him the first president of the United States; their unanimous vote re-elected him in 1792–93; and even after he had positively refused to serve for a third term, two electors obstinately voted for him in 1796–97. The public events of his presidency are given elsewhere (see United States, vol. xxiii. pp. 802–804). One can hardly follow them without receiving the conviction that the sudden success of the new system was due mainly to the existence at that time of such a character as Washington. He held the two natural parties apart, and prevented party contests until the new form of government had been firmly established. It seems hardly possible that the final result should have been baulked, even if "blood and iron" had been necessary to bring it about. It would be unwise to attribute the quiet attainment of the result to the political sense of the American people alone, or to use it as an historical precedent for the voluntary assumption of such a risk again, without the advantage of such a political factor as Washington.

---

[1] [The letter of Gen. Nicola to Washington urging him to allow himself to be crowned as king, had not the sanction of any considerable number of the officers of the revolution.—AM. ED.]

[2] [These were the conventions called to form the Constitution of the U. S.—AM. ED.]

No greater mistake could be made, however, than to think that the influence of the president was fairly appreciated during his term of office. He attempted to balance party against party, to divide his cabinet between them, and to neutralize the effects of parties in that way. The consequence was that the two leading members of the cabinet soon occupied the position, to use the words of one of them, of "two game-cocks in a pit." The unconscious drift of Washington's mind was toward the Federal party; his letters to La Fayette and Henry, in December, 1798, and January, 1799, are enough to make that evident. When the Republican party was formed, about 1793, it could not have been expected that its leaders would long submit with patience to the continual interposition of Washington's name and influence between themselves and their opponents; but they maintained a calm exterior. Some of their followers were less discreet. The president's proclamation of neutrality between France and Great Britain excited them to anger; his support of Jay's treaty with Great Britain roused them to fury. Forged letters, purporting to show that he had desired to abandon the revolutionary struggle, were published; he was accused of drawing more than his salary; hints of the propriety of a guillotine for his benefit began to appear; some spoke of him as the "stepfather of his country." The attacks embittered the close of his term of service; he declared, in a cabinet meeting in 1793, that "he had never repented but once the having slipped the moment of resigning his office, and that was every moment since." Indeed, the most unpleasant portions of Jefferson's *Ana* are those in which, with an air of psychological dissection, he details the storms of passion into which the president was hurried by the newspaper attacks upon him. These attacks, however, came from a very small fraction of the politicians; the people never wavered in their devotion to the president, and his election would have been unanimous in 1796, as in 1789 and 1792, if he had been willing to serve.

All accounts agree that Washington was of imposing presence. He measured just 6 feet when prepared for burial; but his height, in his prime, as given in his orders for clothes from London, was 3 inches more. La Fayette says that his hands were "the largest he ever saw on a man." Custis says that his complexion was "fair, but considerably florid." His weight was about 220 ℔. The various and widely-differing portraits of him find exhaustive treatment in the seventh volume of Winsor's *Narrative and Critical History of the United States*. The editor thinks that "the favorite profile has been unquestionably Houdon's, with Stuart's canvas for the full face, and probably Trumbull's for the figure." Stuart's face, however, gives the popular notion of Washington, though it has always been a subject of curious speculation to some minds how much of the calm and benign expression of the face was due to the shape of Washington's false teeth.[1]

Washington was childless: said the people of his time, he was the father only of his country. Collateral branches of the family have given the Lees, the Custises, and other families a claim to an infusion of the blood; but no direct descendants of Washington can claim his honors, or disgrace his name. His estate of Mount Vernon was acquired in 1858 by an association, and has been practically national property ever since.[2]

Retiring from the presidency in 1797, Washington resumed the plantation life which he most loved, the society of his family, and the care of his slaves. He had resolved some time before never to obtain another slave, and "wished from his soul" that his State could be persuaded to abolish slavery; "it might prevent much future mischief." He was too old, however, to attempt further innovations. In 1798 he was made commander-in-chief of the provisional army raised in expectation of open war with France, and was fretted almost beyond endurance by the quarrels of Federalist politicians about the distribution of commissions. In the midst of his military preparations, he was struck down by sudden illness, which lasted but for a day, and he died at Mount Vernon, December 14, 1799. The third of the series of resolutions introduced in the house of representatives five days after his death, by John Marshall,[3] and passed unanimously, states exactly, if a trifle rhetorically, the position of Washington in American history; "first in war, first in peace, and first in the hearts of his countrymen."

Washington's disorder was an œdematous affection[4] of the wind-pipe, contracted by careless exposure during a ride in a snow-storm, and aggravated by neglect afterwards, and by such contemporary remedies as excessive bleeding, gargles of "molasses, vinegar, and butter" and "vinegar and sage tea," which "almost suffocated him," and a blister of cantharides on the throat. He died without theatrical adieus; his last words[5] were only business directions, affectionate remembrances to relatives, and repeated apologies to the physicians and attendants for the trouble he was giving them. Just before he died, says his secretary, Mr. Lear, he felt his own pulse; his countenance changed; the attending physician placed his hands over the eyes of the dying man, "and he expired without a struggle or a sigh."

Any complete bibliography of books relating to Washington would be voluminous. Lives have been written by Weems, Marshall (1804–7), Ramsay (1807), A. Bancroft (1826), and Irving (1855). See also Sparks's *Writings of Washington* (1834–37); Rush's *Domestic Life of Washington*

WASPS. The order *Hymenoptera* is divided into two sub-orders, the *Terebrantia* and the *Aculeata*. The latter is subdivided into several sub-sections, one of which, the *Diploptera* (Latreille), includes all the true wasps.

The *Diploptera* are in their turn divided into three families—(1) the *Vispidæ*, (2) the *Eumenidæ*, and (3) the *Masaridæ*, which together comprise some 1000 different species. They are characterized by their wings, which are present in both sexes and also in the neuters, being longitudinally folded when at rest. The antennæ are usually elbowed, and contain twelve or thirteen joints; in some cases they are clavate. A pair of notched faceted eyes are present, and three ocelli in the top of the head. The mouth-parts are arranged for sucking, but have not reached that degree of perfection found amongst the bees. Hence wasps cannot obtain the sugary secretion from deeply-seated nectaries, and their visits to flowers are confined to such as are shallow or widely opened; they particularly frequent the *Umbelliferæ*. The maxillæ are elongated, and compressed, the maxillary palp six-jointed. The labium bears a tongue which is glandular at the tip; the paraglossæ are linear. The labial palp has three or four joints. The thorax is oval, and its sides prolonged backward to the base of the wings. The fore wing has two or three submarginal cells. The legs are not provided with any adaptations for collecting pollen. The abdomen is sometimes pedunculate, its anterior segment being drawn out into a long stalk, which connects it with the thorax. The females and the neuters are armed with a powerful sting. The usual color of these insects is black, relieved to a greater or less degree by spots and patches of yellow or buff.

The *Diploptera* may be subdivided into two groups in accordance with the habits of life of the insects comprising the section. One of the groups includes the family *Vespidæ*, which is composed of social wasps, and includes the hornet (*Vespa crabro*) and the common wasp (*V. vulgaris*). The other group contains two smaller families, the *Eumenidæ* and the *Masaridæ*, the members of which are solitary in their mode of life.

Family I. *Vespidæ.*—In addition to their social habits the members of this family are characterized by certain structural features. The anterior wings have three submarginal cells. The antennæ have thirteen joints in the males and twelve in the females; the claws of the tarsi are simple; the anterior four tibiæ have two spines at the tip; the abdomen is but rarely pedunculated, and the posterior segments are often very contractile.

The members of this family approximate very closely to bees in their social manner of life. The communities are composed of males, females, and neuters or workers. The latter are females in which the ovary remains undeveloped; they resemble the perfect female in external appearance, but are slightly smaller. Unlike the bees', the wasps' community is annual, existing for one summer only. Most of the members die at the approach of autumn, but a few females which have been fertilized hibernate through the winter, sheltered under stones or in hollow trees. In the spring and with the returning warm weather the female regains her activity and emerges from her hiding-place. She then sets about finding a convenient place for building a nest and establishing a new colony. The common wasp (*V. vulgaris*) usually selects some burrow or hole in the ground, which, if too small, she may enlarge into a chamber suitable for her purpose. She then commences to build the nest. This is constructed of small fibres of old wood, which the wasp gnaws, and kneads, when mixed with the secretion from the salivary glands, into a sort of papier-mâché pulp. Some of this is formed into a hanging pillar attached to the roof of the cavity, and in the lower free end of this three shallow cup-like cells are hung. In each of these an egg is laid. The foundress of the society then continues to add cells to the comb, and as soon as the grubs appear from the first-laid eggs she has in addition to tend and feed them.

The grubs are apodal, thicker in the middle than at either end; the mandibles bear three teeth; the maxillæ and labium are represented by fleshy tubercles. The body, including the head, consists of fourteen segments, which bear lateral tubercles and spiracles. They have no anus. They are suspended with the head downwards in the cells, and require a good deal of attention, being fed by their mother upon insects which are well chewed before they are given to the larvæ, or upon honey. At the same time the mother is enlarging and deepening the cells in which they live, building new cells, and laying more eggs, which are usually suspended in the same angle of each cell. The development within the egg takes eight days.

After about a fortnight the grubs cease to feed, and, forming a silky cover to their cells, become pupæ. This quiescent stage lasts about ten days, at the end of which period they emerge as the imago or perfect insect. The silky covering of the cell is round or convex outwards; and to leave the cell the insect either pushes it out, when it opens like a box lid, or gnaws a round hole through it. As soon as the cell is vacated it is cleaned out and another egg deposited. In this way two or three larvæ occupy successively the same cell during the summer. The first wasps that appear in a nest are neuters or workers, and these at once set to work to enlarge the comb, and feed the larvæ, etc.

The material which forms the substance of the nest is usually dried wood, worked by the mandibles of the wasp, with the addition of its salivary secretion, into a pulp, which can easily be moulded whilst moist; it dries into a substance of a papery appearance, but possessing considerable tenacity. Sometimes paper itself, such as old cartridge cases, is used. The combs are arranged horizontally; each contains a single layer of cells opening downwards. The second comb is suspended from the first by a number of hanging pillars which are built from the point of union of three cells. The space between two combs is just sufficient to allow the wasps to cross each other. The combs are roughly circular in outline, and increase in size for the first four or five layers, after which they begin to decrease; the whole is covered by a roughly made coating of the same papery substance which composes the combs. This at first forms a cap-shaped protection, but as each comb is built it is continued down until finally it forms a roughly spherical covering for the whole, but not giving any support to the combs, which are independent of it. The covering is pierced by apertures for the passage of the wasps. The cells are hexagonal at their mouths, but above become more rounded in their cross section.

During the first half of the summer only workers are produced, but, as fruit ripens and food becomes more abundant, fully developed females and males appear, the latter from parthenogenetically developed eggs of the later broods of workers. The males and females are larger than the workers, and require larger cells for their development; these are usually kept apart from one another and from those of the workers. The males may be distinguished by their longer antennæ, by the more elongated outline of their body, and by the absence of a sting.

In a favorable season, when the weather is warm and food plentiful, a nest may contain many thousands of cells full of wasps in various stages of development; and, as each cell is occupied two or three times in the course of a summer, those authorities who put the number of the members of the community as high as 30,000 are probably not far wrong.

At the approach of autumn the society begins to break up; the males fertilize the females whilst flying high in the air. They then die, often within a few hours. The workers leave the nest, carrying with them any grubs that remain in the cells, and both soon perish. The nest is entirely deserted. The females which have been fertilized creep into crevices under stones or trees, or hide amongst moss, and hibernate until the warmth of the following spring induces them to leave their hiding-places and set about founding a new community.

There are altogether seven species of *Vespa* met with in Britain. *V. vulgaris*, the common or ground wasp, *V. rufa*, the red wasp, distinguished by its reddish-yellow legs, and *V. germanica*, the German wasp with three black spots upon its first abdominal segment, are classed together as ground wasps. They build their nests in burrows in the ground, but this is not an invariable rule; they may be distinguished from the three wasps by the first joint in the antennæ of the female being black. The tree wasps build stouter nests upon branches of trees; the first joint of the antennæ of the females is yellow in front. The tree wasps are *V. arborea, sylvestris, norwegica,* and *crabro*.

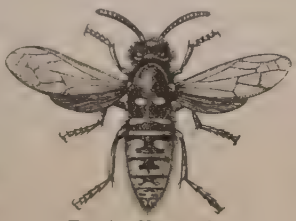

FIG. 1.—*Vespa rufa.*

The hornet, *V. crabro*, is the largest species occurring in Great Britain. They have a more distinctly red color than the common wasp, and a row of red spots upon each side of the abdomen. They occur much more rarely than the common wasp, and appear to be almost confined to the southern half of England. Their nests resemble those described above, but are larger; they are found in hollow trees or deserted out-houses. Their communities are smaller in number than those of wasps.

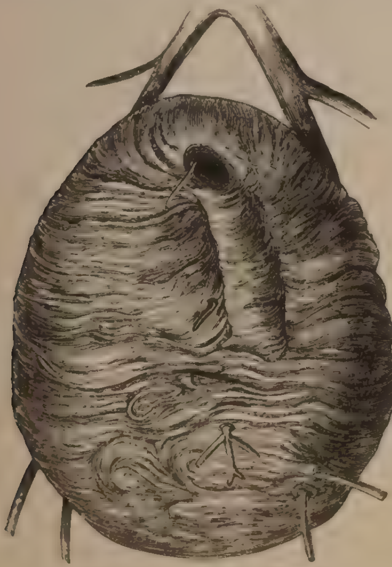

FIG. 2.—Nest of *Vespa sylvestris.*

The hornet, where it occurs in any number, does a considerable amount of damage to forest trees, by gnawing the bark off the younger branches to obtain material for constructing its nest. It usually selects the ash or alder, but sometimes attacks the lime, birch, and willow. Like the wasp, it does much damage to fruit, upon the juices of which it lives. On the other hand, the wasp is useful by keeping down the numbers of flies and other insects. It catches these in large numbers, killing them with its jaws and not with its sting. It then tears off the legs and wings, and bears the body back to its nest as food for the larvæ. Wasps also act to some extent as flower fertilizers, but in this respect they cannot compare with bees; they visit fewer flowers, and have no adaptations on their limbs for carrying off the pollen.

The genus *Vespa* is very widely spread; it contains over forty species, distributed all over the world. Some of the largest and handsomest come from eastern Asia. *V. mandarina* of China and Japan, and *V. magnifica* of the East Indies and Nepal, measure 2 inches across the wings; *V. orientalis*, found in Greece, Egypt, and the East, builds its nest of clay.

The only other genus of *Vespidæ* which is found in Europe is *Polistes*, which occurs in the countries bordering the Mediterranean. The colonies of this genus are much smaller than those of *Vespa*. Each nest consists of a single tier of cells in the form of a round plate, supported in the middle by a single stalk. This comb is sometimes vertical, the cells then being horizontal or slightly oblique. Some of the members of this genus store up honey, which in the case of a South-American species is poisonous, from the nature of the flowers from which it is gathered. The members of this genus have a slender body; the thorax is more oblong than in the genus *Vespa*, the palps stouter, and the abdomen more distinctly pedunculate.

The genus *Ischnogaster*, from the East Indies, has many structural features in common with the *Eumenidæ*, but the character of its communities, and its nest, which is very small, justify its position amongst the social wasps.

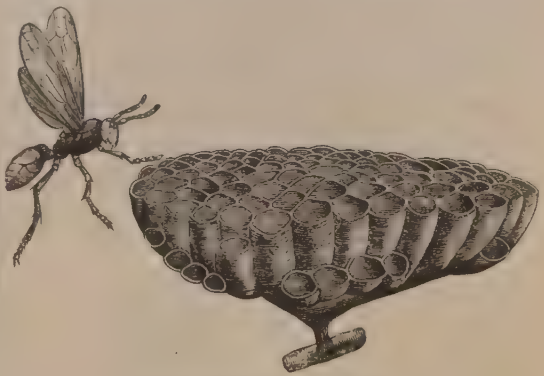

FIG. 3.—*Polistes tepidus* and nest.

The genus *Icaria*, common in Australia and the East Indies, builds very small nests, of two or three rows of cells, hanging on one side from a stalk.

Synœca is a South-American genus, which builds large nests, sometimes three feet in length, closely applied to the branch of a tree; they never contain more than one layer of cells, which are horizontally placed. The whole nest is built of coarse material, chiefly small pieces of bark; and there is only one opening, at the lower end.

Another South-American genus, *Chartergus*, makes a tough nest, pendant from boughs of trees, and opening to the exterior below by a median aperture. The combs are arranged, somewhat like funnels, inside one another, but with spaces between. The apex of each comb is pierced by a hole for the wasps to pass from one gallery to another.

The nest of *Tatua*, which occurs in Mexico and South America, is also pendant, but the combs are horizontal; the opening from the exterior is at the side, and the passage from one gallery to another is also lateral.

The external appearance of the nest of *Nectarina*, found in Brazil and other parts of South America, resembles that of the common wasp, but is rougher. Internally the combs are arranged concentrically, more or less parellel with the external covering which affords them support.

The members of the two remaining families, the *Eumenidœ* and the *Masaridœ*, resemble one another in their solitary mode of life; only male and females exist,—no workers or neuters being found.

Family II. *Eumenidœ.*—Solitary species, with three submarginal cells in the fore wing; antennæ with thirteen joints in the male, twelve in the female; abdomen sometimes pedunculate, posterior segments contractile. In the foregoing structural features the *Eumenidœ* resemble the *Vespidœ*, but they differ in having bifid claws on their tarsi, and the four anterior tibiæ have but one spine at the tip. The mandibles are elongated, and form a kind of rostrum, in this respect approaching the *Fossores*.

Eumenes coarctata is the only British species of this genus. The female is half an inch long, the male somewhat shorter. The abdomen is connected with the thorax by a long peduncle. The color is black, relieved by spots of yellow. It constructs small spherical cells of mud, which are found attached to stems of plants, very generally to the heath. At first the cell opens to the exterior by means of a round pore; one egg is deposited in each cell, and a store of honey as food for the larva when hatched; the cell is then closed with mud. The larva of some species are carnivorous, and then the food supply stored up in the cell consists of caterpillars and other insect larvæ which have been paralyzed by the parent wasp stinging them through the cerebral ganglion; when the larva of the *Eumenes* emerges from the egg it sets upon these and devours them.

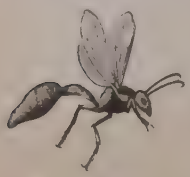

FIG. 4.—*Eumenes smithii.*

The genus *Odynerus* contains a very large number of species, found in all parts of the world. The members of this genus are about the size of a fly, and they differ from *Eumenes* in having a sessile abdomen. Some of the species construct their cells in sand heaps, lining them with agglutinated grains of sand; others live in cavities of trees lined with the same material, whilst others build their nests of mud. Like some of the species of *Eumenes*, they store up paralyzed Lepidopterous and Chrysomeleous larvæ as food for their carnivorous grubs.

Family III. *Masaridæ.*—The members of the third family, the *Masaridæ*, are sharply distinguished by the possession of only two submarginal cells in the fore wing. Their antennæ are frequently clavate, particularly so in the genus *Celonites*; they are twelve-jointed, but as the terminal joints are almost fused they appear to be composed of only eight joints. The wings are not so completely folded as in the other two families, and the abdomen is but slightly contractile. The maxillæ are short and their palps very small, with but three or four joints.

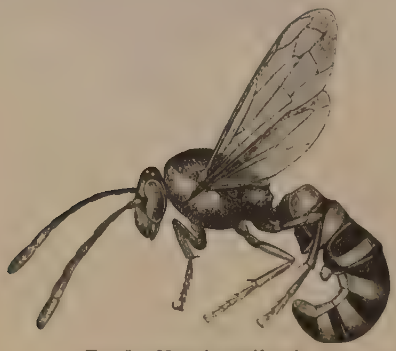

FIG. 5.—*Masaris vespiformis.*

The number of genera comprised in this family is small; none occur in Britain, but in southern Europe some species are found. They make their nest in cavities in the earth, generally in a bank, and construct an irregular gallery leading down to it.

During hot fine summers wasps cause a good deal of loss to market gardeners and fruit growers. During this time of the year they live almost exclusively upon the sweet juices of ripe fruit, occasionally carrying off small particles of the flesh. At the same time they have not entirely lost their carnivorous tastes, for they frequently attack the meat in butchers' shops, but render compensation by killing and carrying off to feed their grubs considerable numbers of blow-flies. Wasps also perform an important service in keeping down the numbers of caterpillars. The larvæ are almost exclusively carnivorous, living upon insects captured by their parents and reduced by them to a pulp before being given to the young. During the spring the first broods that appear live largely upon honey; and this forms the staple food of the genus *Polistes* throughout their whole life.

In attempting to rid a district of wasps, unless the nest can be taken, there is little good in killing stray members of the community. On the other hand, the killing of wasps in early spring probably means that the formation of a nest and the production of a society whose members are counted by thousands is in each case prevented.

The number of wasps is kept down by numerous enemies. The most effective of these live in the nests and devour the larvæ; among them are two species of beetle, *Rhipiphorus paradoxus* and *Lebia linearis.* Two species of *Ichneumon*, a species of *Anthomyia*, and the larva of a *Volucella* also infest the nests of wasps and prey upon the grubs. The last-named is also found in beehives. In the tropics some species are attacked by fungi, the hyphæ of which protrude between the segments of the abdomen, and give the wasp a very extraordinary appearance. (A. E. S.)

WASTE (*Vastum*) is used in law in several senses, of which four are the most important. (1) Waste of a manor is that part of a manor subject to rights of common, as distinguished from the lord's demesne (see COMMONS, MANOR). (2) Year, day, and waste was a part of the royal prerogative, acknowledged by the statute *De Prærogativa Regis.* The king had the profits of freehold lands of those attainted of felony and petit treason and of fugitives for a year and a day with a right of committing waste in sense (3) thereon. After the expiration of a year and a day the lands returned to the lord of the fee. Attainder for felony being now abolished, the right has ceased to exist (see FELONY, TREASON). (3) The most usual signification of the word is "any unauthorized act of a tenant for a freehold estate, not of inheritance or for any lesser interest, which tends to the destruction of the tenement, or otherwise to the injury of the inheritance" (Pollock, *Law of Torts*, p. 285). Waste is either voluntary or permissive. Voluntary waste is by act of commission, as by pulling down a house, cutting down trees, opening new quarries or mines (though not continuing the working of existing ones), or doing anything which may destroy evidence, such as conversion of arable into meadow land. Permissive waste is by act of omission, such as allowing buildings to fall out of repair. A fermor, by the Statute of Marlbridge, 52 Hen. III. c. 23, may not commit waste without license in writing from the reversioner. The same statute mentions a form of waste which has long become extinct, viz., exile (*exilium*), or the impoverishment of villeins or tenants at will on an estate. In case a tenant for life or for any smaller interest holds (as is often the case by the terms of a will or settlement) without impeachment of waste, his rights are considerably greater, and he may use the profits *salva rerum substantia* (to use the language of Roman law). For instance, he may cut timber in a husband-like manner and open mines, but he may not commit what is called equitable waste, that is, pull down or deface the mansion or destroy ornamental timber. Acts of equitable waste were, before 1875, not cognizable in courts of common law, but it is now provided by the Judicature Act, 1873, § 25 (3), that in the absence of special provision to that effect an estate for life without impeachment of waste shall not confer upon the tenant for life any legal right to commit equitable waste. Removal of fixtures, which would be *prima facie* waste, is recognized by the law to a limited extent (see FIXTURES). A copy-holder may not commit waste unless allowed by the custom of the manor (see COPYHOLD). Various remedies for waste have been given to the reversioner at different periods of law. At common law only single damages seem to have been recoverable. This was altered by the legislature, and for some centuries waste was a criminal or quasi-criminal offence. Magna Charta enacted that a guardian committing waste of the lands in his custody should make amends and lose his office. The Statute of Marlbridge made a fermor committing waste liable to grievous amerciament as well as to damages, and followed Magna Charta in forbidding waste by a guardian. The Statute of Gloucester, 6 Edw. I. c. 5, enacted that a writ of waste might be granted against a tenant for life or years or in courtesy or dower, and on being attainted of waste the tenant was to forfeit the land wasted and to pay thrice the amount of the waste. In addition to the writ of waste the writ of estrepement (said to be a corruption of *extirpamentum*) lay to prevent injury to an estate to which the title was disputed. Numerous other acts dealt with remedies for waste. The writ of waste was superseded at common law by the mixed action of waste, itself abolished by 3 and 4 Will. IV. c. 27, and the action of trespass on the case (see Tort, Trespass). The Court of Chancery also established a jurisdiction by suit or injunction, especially to restrain equitable waste. At present proceedings may be taken either by action for damages, or by application for an injunction, or by both combined, and either in the Queen's Bench or Chancery Division. By the Judicature Act, 1873, § 25 (8), the old jurisdiction to grant injunctions to prevent threatened waste is considerably enlarged. The rules of the Supreme Court, 1883, Ord. xvi. r. 37, enable a representative action to be brought for the prevention of waste. In order to obtain damages or an injunction, substantial injury or danger of it must be proved. In England only the High Court (unless by agreement of the parties) has jurisdiction in questions of waste, but in Ireland the civil bill courts and courts of summary jurisdiction have coordinate authority to a limited extent. The law of waste as it affects ecclesiastical benefices will be found under Dilapidations. (4) Waste of assets or *devastavit* is a squandering and misapplication of the estate and effects of a deceased person by his executors or administrators, for which they are answerable out of their own pockets as far as they have or might have had assets of the deceased. The legal liability of the representatives of the deceased is recognized by 30 Car. II. c. 7 and 4 W. and M. c. 24.

In Scots law waste is not used as a technical term, but the respective rights of fiar and liferenter are much the same as in England. The latter, however, has not the right of continuing the working of existing mines unless the deed specially confers it upon him. Interdicts have in strong cases been granted against the sale of ornamental timber.

In the United States, especially in the western States, many acts, such as the felling of timber, are not considered waste which would be waste in England. In some States waste is a cause of forfeiture; in some it gives a right to treble damages. The writ of estrepement is still in use.

WATCH. Timepieces moved by a spiral spring instead of a weight were made as early as the 16th century, though the law which governs the mechanical theory of springs was first enunciated by Huygens in the 17th century (*ut tensio sic vis*); this, however, is not invariable.

Fig. 1 shows the general arrangement of a watch or chronometer (both of which are here considered together). The barrel and fusee will be recognized at once. The fusee is a sort of grooved hollow-sided cone; the more rapid swell towards the thick end is required, because one turn of the fusee, when the chain is at that end, takes much more of it off the barrel than at the thin end; and on the assumption that the force of the spring varies as its tension the radius of the cone must increase more rapidly, in order to make the increase of leverage keep pace with the decrease in the force of the spring as it unwinds with an increasing velocity off the thick end of the fusee. The fusee itself is connected with the great wheel by a ratchet and click and going ratchet (of which the spring and click are strongly shown in the figure), just as described under Clocks (vol. vi. p. 13). Something is also required to prevent the watch from being overwound, or the chain strained so as to break. This is done by means of a hooked lever, set on a hinge in the upper frame-plate (which is taken off in this drawing); and when the watch is nearly wound up the chain moving upwards reaches this lever, and moves it into such a position that its hook catches hold of the long tooth projecting from the thin end of the fusee; and thus the winding is stopped without any strain on the chain by the sudden check.

By far the greater number of watches now made both on the Continent and in America have the mechanism known as the going barrel in substitution for the chain and fusee. In the going barrel the mainspring is of great length, and only a few coils of it are brought into action. To the going barrel itself the main wheel is attached, and thus the force of the mainspring is transmitted direct to the escapement. The general adoption of the going barrel mechanism is due to the introduction of keyless winding, which can only be adapted to the fusee watches with difficulty, and to the greater cheapness of the arrangement. Moreover, it is found that for three or four coils of a long spring, at a certain degree of winding up, the tension varies very little. The going barrel is not used in the best English work, in which absolute uniformity of motion is aimed at; but for ordinary purposes it is not of so much consequence that the same rate from hour to hour should be maintained provided the daily rate is uniform.

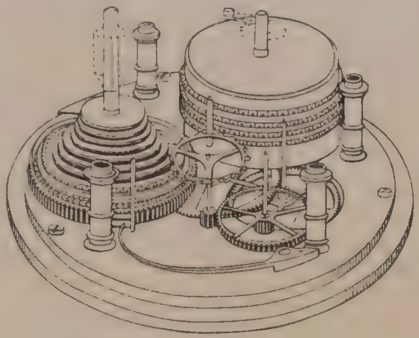

Fig. 1.

In watches without a fusee the apparatus for preventing overwinding is different from that in the old form of watch; it goes by the name of the Geneva stop, and the principle of it is simple. If two wheels work together, of which one has the spaces between some two or more adjacent teeth filled up, it is evident that that wheel cannot be turned quite round. And it will be the same thing if one of the wheels is only a cylinder with a single tooth in it, and the other has a certain number of notches, not going all round, through which that tooth can pass. If, therefore, a one-toothed wheel of this kind is fixed to the barrel arbor which is turned by the key, and works into a wheel with only 4 or 5 notches in it and a blank space through which the tooth cannot pass, it will evidently allow the barrel to be wound up the 4 or 5 turns and no more; and as it unwinds it turns the stopping wheel back again with it.

The other parts of a watch do not differ from those of a clock, except in size, and the position in which they are arranged, to bring them within the circle of the dial, until we come to the escapement; and there a different state of things arises, mainly from the fact that the balance of a watch revolves through sometimes as much as 270°, while a clock pendulum only vibrates through 4° or 5°. The balance being common to all the watch escapements, it will be proper first to describe that and the conditions to which it is subject. The two equal arms, with equal weights at each end, in Fig. 3 of article Clocks (vol. vi. p. 17) are really a balance just as much as the wheel which is commonly used as the more convenient form. But in that figure there is not to be seen that essential element of a modern balance—the thin spiral spring, opening and closing itself at every vibration. The outer end of this spring is attached to the frame by a cock R (Fig. 2), and the inner to the balance at S; and the time of vibration depends only on the strength of the spring and the moment of inertia of the balance, and not at all upon the extent or angle of the vibration. And, as the force of a spring varies (approximately) inversely as its length, this suggests a ready method of regulating the watch; for it is easy to make a pointer or index, or "regulator" PT, turning on a ring fixed to the watch plate, concentric with the balance, and having two pins in it at P, called *curb pins*, just close enough together to embrace the spring, so that, as the index is moved one way or the other, the length of the spring which is free to vibrate may become shorter or longer. When the regulator has been moved as far as it can go towards *fast*, suppose, and the watch still loses, the spring has to be shortened at the cock R into which its outer end is pinned; and, in order that the balance may be capable of alteration, so as still to stand square with the escapement when the spring is in its neutral state, the other end is not actually pinned to the balance, but the cock S is on a small ring which is set on the axis or *verge* of the balance pretty tight by friction, but capable of being turned by hand. An index-plate like that in Fig. 2 enables one to see smaller movements of the index than radial marks.

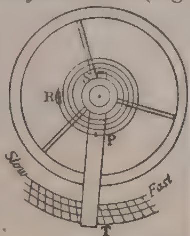

FIG. 2.

It is almost impossible to move such a regulator little enough, and with sufficient accuracy, for a very small variation of rate. One way of obtaining greater accuracy, and probably the best, is to make the regulator movable by a tangent screw acting on its end, and capable of being turned by the watch key. Another mode of giving a small motion to the regulator is by putting a portion of a wheel with teeth on it, and turning it by a small pinion with the index attached to it, so that the motion of the index exceeds that of the regulator itself as much as the radius of that wheel exceeds the radius of the pinion. Chronometers are regulated in a different way altogether. It is not expedient to alter the effective length of the spring after its length is once fixed. For it has long been ascertained that a spring does not give isochronous vibrations at all lengths, but only at certain intervals; and therefore it is necessary in an accurate timekeeper to use only one of those lengths of the spring which are found to be isochronous for different arcs of vibration; and, that being fixed, the timing of the balance can only be done by altering its moment of inertia, and this is done in chronometers by screws with heavy heads in the rim of the balance, set farther in or out as it is wanted to go faster or slower. In marine chronometers, where there is plenty of room for it, the balance-spring is generally made in a cylindrical form, with the coils all of the same diameter, instead of the flat spiral used in watches,—though it does not seem to be quite clear that the cylindrical form is materially better than the other.

The timing of a watch for position, as it is called, is a matter which requires some attention. If the balance is not exactly poised on its axis, it will have a tendency to take one position when the watch is carried vertically, as it always is in the pocket; and the time of vibration will be affected by its disposition thus to act as a pendulum. The watch ought therefore to be tried with XII, IX, VI, and III successively upwards, and if it does not keep the same rate the balance is not properly poised. Marine chronometers, indeed, being set in *gimbals* (a ring with the two pivots into the box at right angles with the pivots which carry the chronometer), will remain horizontal, though not without some degree of motion under the motion of the ship; and this gives the balance the further advantage of having its weight resting only on the end of the axis or verge, a position in which there is much less friction than that of a watch carried in the pocket; but there it is not of so much consequence, because the balance is so much lighter than a chronometer balance.

Compensated Balances.—A pendulum requires scarcely any compensation except for its own elongation by heat; but a balance requires compensation, not only for its own expansion, which increases its moment of inertia just like the pendulum, but far more on account of the decrease in the strength of the spring under increased heat. Dent, in a pamphlet on compensation balances, gave the following results of some experiments with a glass balance, which he used for the purpose on account of its less expansibility than a metal one: at 32° F., 3606 vibrations in an hour; at 66°, 3598.5; and at 100°, 3599. If therefore it had been adjusted to go right (or 3600 times in an hour) at 32°, it would have lost 7½ and 8½ seconds an hour, or more than three minutes a day, for each successive increase of 34°, which is about fifteen times as much as a common wire pendulum would lose under the same increase of heat; and if a metal balance had been used instead of a glass one the difference would have been still greater.

The necessity for this large amount of compensation having arisen from the variation of the elasticity of the spring the first attempts at correcting it were by acting on the spring itself in the manner of a common regulator. Harrison's compensation consisted of a compound bar of brass and steel soldered together, having one end fixed to the watch-frame and the other carrying two curb pins which embraced the spring, as was described at Fig. 2. As the brass expands more than the steel, any increase of heat made the bar bend; and so, if it was set the right way, it carried the pins along the spring, so as to shorten it. This contrivance is called a *compensation curb;* and it has often been reinvented, or applied in a modified form. But there are two objections to it: the motion of the curb pins does not correspond accurately enough to the variations in the force of the spring, and it disturbs the isochronism, which only subsists at certain definite lengths of the spring.

The compensation which was next invented left the spring untouched, and provided for the variations of temperature by the construction of the balance itself. Fig. 3 shows the plan of the ordinary compensation balance. Each portion of the rim of the balance is composed of an inner bar of steel with an outer one of brass soldered upon it, and carrying the weights, *b,b*, which are screwed to it. As the temperature increases, the brass expanding must bend the steel inwards and so carries the weights farther in, and diminishes the moment of inertia of the balance. The metals are generally soldered together by pouring melted brass round a solid steel disk, and the whole is afterwards turned and filed away till it leaves only the crossbar in the middle lying flat and the two portions of the rim standing edgeways. The first person who practiced this method of uniting them appears to have been Thomas Earnshaw, who brought the chronometer to the state in which it has remained for the last century, with scarcely any alteration except more complete compensation.

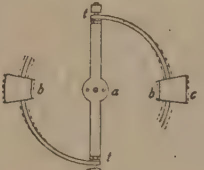

FIG. 3.

The adjustment of a balance for compensation can only be done by trial, and requires a good deal of time. It must be done independently of that for time,—the former by shifting the weights, because the nearer they are to the crossbar the less distance they will move over as the rim bends with them. The timing is done by screws with heavy heads (*t*, *t*, Fig. 3), which are just opposite to the ends of the crossbar, and consequently not affected by the bending of the rim. The compensation may be done approximately by the known results of previous experience with similar balances; and many watches are sold with compensation balances which have never been tried or adjusted, and sometimes with a mere sham compensation balance, not even cut through.

Secondary Compensation.—When chronometers had been brought to great perfection it was perceived that there was a residuary error, which was due to changes of temperature but which no adjustment of the compensation would correct. For, if the compensation was adjusted for two extreme temperatures, such as 32° and 100°, then the chronometer gained at mean temperatures; and, if adjusted for any two mean temperatures, it would lose for all beyond them. This error was observed, and attempts were made to correct it before anybody had pointed out how it arose: this appears to have been first done in a paper in the *Nautical Magazine* by E. J. Dent in 1833; and he gave the following illustration of it. The variation of the force of the spring proceeds uniformly in proportion to the temperature, and therefore may be represented by a straight line inclined at some angle to another straight line divided into degrees of temperature. But the inertia of a balance of the common construction cannot be made to vary uniformly according to the temperature, but will vary more rapidly in cold than heat; and consequently its rate of variation can only be represented by a curve, and the curve can only be made to coincide with the straight line representing the rate of variation of the spring in two points,—either two extremes, or two means, or one extreme and one mean point.

The same thing may be shown mathematically, as follows. Let r be the distance of the compensation weights b, b, in Fig. 3 (which we may assume for convenience to be the whole mass M of the balance) from the centre at some mean temperature and let dr be their increase of distance due to a decrease of some given number of degrees of heat under the action of the compensation bars. Then the new moment of inertia will be M $(r^2 + 2rdr + dr^2)$, and the ratio of the new to the old will be $1 + \frac{2dr}{r} + \left(\frac{dr}{r}\right)^2$; and the term $\left(\frac{dr}{r}\right)^2$ is now too large to be disregarded, as it might be in pendulums, where the compensation $\frac{dl}{l}$ is only required to be about $\frac{2}{20}$th of the $\left(\frac{dr}{r}\right)$ in a balance. It is found that an equal increase of temperature will produce an equal or rather a less motion $(-dr)$ of the weights towards the centre than from it at any given point; but, calling it only equal, the ratio of the decreased moment of inertia to the original one will be $1 - \frac{2dr}{r} + \left(\frac{dr}{r}\right)^2$, so that the increase and the decrease from the mean amount differ by twice $\left(\frac{dr}{r}\right)^2$; in other words, the moment of inertia of the balance varies less in passing from mean to hot temperature than from mean to cold; and consequently if it is adjusted for mean and cold it will not have decreased enough at an equal increase from mean to hot, or the chronometer will lose, and if adjusted for the two extremes it will gain at mean temperatures.

The correction of this error is called the *secondary compensation*. We shall give a short description of the principal classes of inventions for this purpose.

The first that was disclosed was Eiffe's (sometimes called Molyneux's), communicated to the astronomer-royal in 1835. In one of several methods proposed by him a compensation curb was used; and, though, for the reasons given before, this will not answer for the primary compensation, it may for the secondary, where the motion required is very much smaller. In another the primary compensation bar, or a screw in it, was made to reach a spring set within it with a small weight attached at some mean temperature, and, as it bent farther in, it carried this secondary compensation weight along with it. The obvious objection to this is that it is discontinuous; but the whole motion is so small, not more than the thickness of a piece of paper, that this and other compensations on the same principle appear to have been on some occasions quite successful. Molyneux took a patent for a secondary compensation exactly the same as this of Eiffe's, then before the astronomer-royal.

Another large class of balances, all more or less alike, may be represented by E. J. Dent's, which came next in order of time. He described several forms of his invention; the following description applies to the one he thought the best. In Fig. 4 the flat crossbar *rr* is itself a compensation bar which bends upwards under increased heat; so that, if the weights *v*, *v* were merely set upon upright stems rising from the ends of the crossbar, they would approach the axis when that bar bends upwards. But, instead of the stems rising from the crossbar, they rise from the two secondary compensation pieces *stu*, in the form of staples, which are set on the crossbar; and, as these secondary pieces themselves also bend upwards, they make the weights approach the axis more rapidly as the heat increases; and by a proper adjustment of the height of the weights on the stems the moment of inertia of the balance can be made to vary in the proper ratio to the variation of the intensity of the spring. The cylindrical spring stands above the crossbar and between the staples.

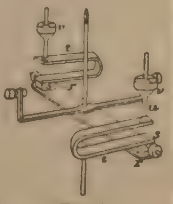

FIG. 4.

Fig. 5 represents Loseby's mercurial compensation balance. Besides the weights D, D, set near the end of the primary compensation bars B, B, there are small bent tubes FE, FE with mercury in them like a thermometer, the bulbs being at F, F. As the heat increases, not only do the primary weights D, D and the bulbs F, F approach the centre of the balance, but some of the mercury is driven along the tube, thus carrying some more of the weight towards the centre, at a ratio increasing more rapidly than the temperature. The tubes are sealed at the thin end, with a little air included. The action is here equally continuous with Dent's, and the adjustments for primary and secondary compensation are apparently more independent of each other; and this modification of Le Roy's use of mercury for compensated balances (which does not appear to have answered) is certainly very elegant and ingenious. Nevertheless an analysis of the Greenwich lists for seven years of Mr. Loseby's trials proved that the advantage of this method over the others was more theoretical than practical; Dent's compensation was the most successful of all in three years out of the seven, and Loseby's in only one. Loseby's method has never been adopted by any other chronometer-maker, whereas the principles both of Eiffe's and of Dent's methods have been adopted by several other makers.

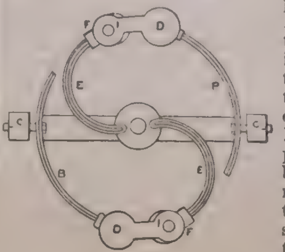

FIG. 5.

A few chronometers have been made with glass balance-springs, which have the advantage of requiring very little primary and no secondary compensation, on account of the very small variation in their elasticity, compared with springs of steel or any other metal.

Dent also invented a very different method of effecting the primary and secondary compensation at once, and without any additional appendage to the balance or addition to the cost. He called it the *prismatic balance*, from the shape of the steel rim, of which the section is shown in Fig. 6, BC being the brass, and the dark triangle within it the section of the steel part of the rim. A prism of cast-steel will bend more easily from the edge than the other way, and consequently the motion is greater when it is being curved by heat than when it is pulled straighter by cold, which is exactly what is wanted. The difference is not quite so great as it ought to be for complete secondary compensation for a very wide range of temperature, but it is enough to give the requisite compensation for all ordinary variations of temperature, and chronometers so compensated were found to be also more than usually steady in their rate, for even in the best chronometers there appear every now and then quite capricious variations.

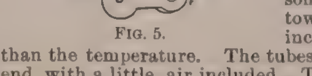

FIG. 6.

Several other forms of secondary compensation have been invented and found successful, all on the same principle of so arranging the compound bars that the weights move more under any given change of temperature in hot weather, or when they are nearest to the axis of the balance, than in cold when they are farthest off. Notices of these may be seen in various volumes of the *Horological Journal*.

The best chronometers with all these improvements, cannot be relied on to keep a rate equal to that of a good astronomical clock of the usual kind, though they occasionally do so for a short time.

Watch Escapements.—The escapements in practical use are —(1) the old *vertical* escapement, now almost disused; (2) the *lever* very much the most common in English watches; (3) the *horizontal* or *cylinder*, which is equally common in foreign watches, though it was of English invention; (4) the *duplex* which used to be more in fashion for first-rate watches than it is now; and (5) the *detached* or *chronometer* escapement, so called because it is always used in marine chronometers.

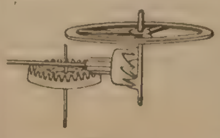

FIG. 7.

The *vertical* escapement is simply the original clock escapement (see CLOCKS, Fig. 3) adapted to the position of the wheels in a watch and the balance, in the manner exhibited in Fig. 7. As it requires considerable thickness in the watch, it is inferior in going to all the others, and no cheaper than the lever escapement can now be made; and for these reasons it has gone out of use.

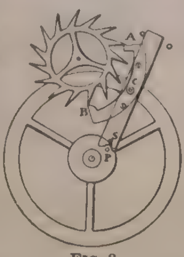

FIG. 8.

The *lever* escapement, as it is now universally made, was invented late in the last century by Thomas Mudge. Fig. 8 shows its action. The position of the lever with reference to the pallets is immaterial in principle, and is only a question of convenience in the arrangement; but it is generally such as we have given it. The principle is the same as in the dead-beat escapement clock (see CLOCKS, Fig. 5), with the advantage that there is no friction on the dead faces of the pallets beyond what is necessary for locking. The reason why this friction cannot be avoided with a pendulum is that its arc of vibration is so small that the requisite depth of intersection cannot be got between the two circles described by the end S of the lever and any pin in the pendulum which would work into it; whereas, in a watch, the pin P, which is set in a cylinder on the verge of the balance, does not generally slip out of the nick in the end of the lever until the balance has got 15° past its middle position. The pallets are undercut a little, as it is called, *i.e.*, the dead faces are so sloped as to give a little recoil the wrong way, or slightly to resist the unlocking, because otherwise there would be a risk that a shake of the watch would let a tooth escape while the pin is disengaged from the lever. There is also a further provision added for safety. In the cylinder which carries the impulse pin P there is a notch just in front of P, into which the other pin S on the lever fits as they pass; but when the notch has got past the cylinder it would prevent the lever from returning, because the safety-pin S cannot pass except through the notch, which is only in the position for letting it pass at the same time that the impulse pin is engaged in the lever. The pallets in a lever escapement (except bad and cheap ones) are always jewelled, and the scape-wheel is of brass. The staff of the lever also has jewelled pivot-holes in expensive watches, and the scape-wheel has in all good ones. The holes for the balance-pivots are now always jewelled, if nothing else is. The scape-wheel in this and most of the watch escapements generally beats five times in a second, in large chronometers four times; and the wheel next to the scape-wheel carries the seconds-hand. Macdowall's single-pin escapement was adapted to watches exactly as the dead escapement of clocks is turned into the lever escapement of watches.

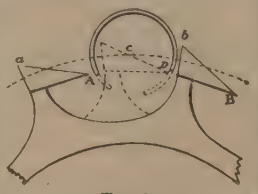

FIG. 9.

Fig. 9 is a plan of the *horizontal* or *cylinder* escapement, cutting through the cylinder, which is on the verge of the balance, at the level of the tops of the teeth of the escape-wheel; for the triangular pieces A, B are not flat projections in the same plane as the teeth, but are raised on short stems above the plane of the wheel; and still more of the cylinder than the portion shown at ACD is cut away where the wheel itself has to pass. The author of this escapement was Graham, and it resembles his dead escapement in clocks in principle more than the lever escapement does, though much less in appearance, because in this escapement there is the dead friction of the teeth against the cylinder, first on the outside, as here represented, and then on the inside, as shown by the dotted lines, during the whole vibration of the balance, except that portion which belongs to the impulse. The impulse is given by the oblique outside edges A*a*, B*b* of the teeth against the edges A, D of the cylinder alternately. The portion of the cylinder which is cut away at the point of action is about 30° less than the semicircle. The cylinder itself is made either of steel or ruby, and, from the small quantity of it which is left at the level of the wheel, it is evidently a very delicate affair; and probably this has been the main reason why, although it is an English invention, it has been almost entirely abandoned by the English watchmakers in favor of the lever, which was originally a French invention, though very much improved by Mudge, for before his invention the lever had a rack or portion of a toothed wheel on its end, working into a pinion on the balance verge, and consequently it was affected by the dead friction, and that of this wheel and pinion besides. This used to be called the rack lever, and Mudge's the detached lever; but, the rack lever being now quite obsolete, the word "detached" has become detached from the lever escapement, and confined to the chronometer, to which it is more appropriate, as will be seen presently. The Swiss watches have almost universally the horizontal escapement. It is found that—for some reason which is apparently unknown, as the rule certainly does not hold in cases seemingly analogous—a steel scape-wheel acts better in this escapement than a brass one, although in some other cases steel upon steel or even upon a ruby, very soon throws off a film of rust, unless they are kept well oiled, while brass and steel, or stone will act with scarcely any oil at all, and in some cases with none.

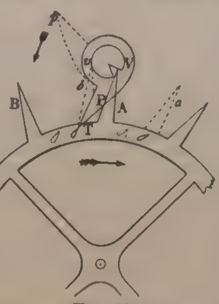

FIG. 10.

The *duplex* escapement (Fig. 10) is probably so called because there is a double set of teeth in the scape-wheel,—the long ones (like those of the lever escapement in shape) for locking only, and short ones (or rather upright pins on the rim of the wheel) for giving the impulse to the pallet P on the verge of the balance. It is a single-beat escapement; *i.e.*, the balance only receives the impulse one way, or at every alternate beat, as in the chronometer escapement, and in a few clock escapements which have never come into use. When the balance is turning in the direction marked by the arrow, and arrives at the position in which the dotted tooth *b* has its point against the triangular notch V, the tooth end slips into the notch, and, as the verge turns farther round, the tooth goes on with it till at last it escapes when the tooth has got into the position A; and by that time the long tooth or pallet which projects from the verge has moved from *p* to P, and just come in front of the pin T, which stands on the rim of the scape-wheel, and which now begins to push against P, and so gives the impulse until it also escapes when it has arrived at *t*; and the wheel is then stopped by the next tooth B having got into the position *b*, with its point resting against the verge, and there is evidently what we have called dead friction between them; but, as the verge is smaller than the cylinder of the horizontal escapement, and is also made of a jewel, the friction does not seriously affect the motion of the balance. The impulse is also given very directly across the line of centres, and therefore with very little friction, as in the three-legged dead escapement for clocks and in the chronometer escapement. A little impulse is also received from the long teeth on the notch; but the greatest part of that motion is wasted. As the balance turns back, the nick V goes past the end of the tooth *b*, and in consequence of its smallness, it passes without visibly affecting the motion of the scape-wheel, though of course it does produce a very slight shake in passing. It is evident that, if it did not pass, the tooth could not get into the nick for the next escape. The objection to this escapement is that it requires very great delicacy of adjustment, and the watch also requires to be worn carefully; for, if by accident the balance is once stopped from swinging back far enough to carry the nick V past the tooth end, it will stop altogether, as it will lose still more of its vibration the next time from receiving no impulse. The performance of this escapement, when well made, and its independence of oil, are nearly equal to those of the detached escapement; but, as lever watches are now made sufficiently good for all but astronomical purposes, for which chronometers are used, and they are cheaper both to make and to mend than duplex ones, the manufacture of duplex watches has almost disappeared.

The *chronometer* or *detached* escapement is shown at Fig. 11, in the form to which it was brought by Earnshaw nearly a century ago, and in which it has remained ever since, with the very slight difference that the pallet P, on which the impulse is given (corresponding exactly to the pallet P in the duplex escapement), is now generally set in a radial direction from the verge, whereas Earnshaw made it sloped backward, or undercut, like the scape-wheel teeth. The early history of escapements on this principle does not seem to be very clear. They appear to have originated in France; but there is no doubt that they were considerably improved by the first Arnold, who died in 1799. Earnshaw's watches, however, generally beat his in trials.

In Fig. 11 the small tooth or cam V, on the verge of the balance, is just on the point of unlocking the detent DT from the tooth T of the scape-wheel; and the tooth A will immediately begin to give the impulse on the pallet P, which, in good chronometers, is always a jewel set in the cylinder; the tooth V is also a jewel. This part of the action is so evident as to require no further notice. When the balance returns, the tooth V has to get past the end

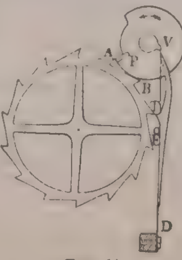

FIG. 11.

of the detent, without disturbing it; for, as soon as it has been unlocked, it falls against the banking-pin E, and is ready to receive the next tooth B, and must stay there until it is again unlocked. It ends, or rather begins, in a stiffish spring, which is screwed to the block D on the watch frame, so that it moves without any friction of pivots, like a pendulum. The passing is done by means of another spring TV, called the passing spring, which can be pushed away from the body of the detent towards the left, but cannot be pushed the other way without carrying the detent with it. In the back vibration, therefore, as in the duplex escapement, the balance receives no impulse, and it has to overcome the slight resistance of the passing spring besides; but it has no other friction, and is entirely *detached* from the scape-wheel the whole time, except when receiving the impulse. That is also the case in the lever escapement; but the impulse in that escapement is given obliquely, and consequently with a good deal of friction; and, besides, the scape-wheel only acts on the balance through the intervention of the lever, which has the friction of its own pivots and of the impulse pin. The locking-pallet T is undercut a little for safety, and is also a jewel in the best chronometers; and the passing spring is of gold, as steel will rust. In the duplex and detached escapements, the timing of the action of the different parts requires great care, *i.e.*, the adjusting them so that each may be ready to act exactly at the right time; and it is curious that the arrangement which would be geometrically correct, or suitable for a very slow motion of the balance, will not do for the real motion. If the pallet P were really set so as just to point to the tooth A in both escapements at the moment of unlocking (as it has been drawn, because otherwise it would look as if it could not act at all), it would run away some distance before the tooth could catch it, because in the duplex escapement the scape-wheel is then only moving slowly, and in the detached it is not moving at all, and has to start from rest. The pallet P is therefore, in fact, set a little farther back, so that it may arrive at the tooth A just at the time when A is ready for it, without wasting time and force in running after it. This, however, seems now to be doubted in practice. The detached escapement has also been made on the duplex plan of having long teeth for the locking and short ones or pins nearer the centre for the impulse; but the advantages do not appear to be worth the additional trouble, and the force required for unlocking is not sensibly diminished by the arrangement, as the spring D must in any case be pretty stiff, to provide against the watch being carried in the position in which the weight of the detent helps to unlock it.

An escapement called the *lever chronometer* has been several times reinvented, which implies that it has never come into general use. It is a combination of the lever as to the locking and the chronometer as to the impulse. It involves a little drop and therefore waste of force as a tooth of the wheel just escapes at the "passing" beat where no impulse is given. But it should be understood (as it is not by some who write on clock-work) that a single-beat escapement involves no more loss of force and the escape of no more teeth than a double one, except the slight drop in the duplex and this lever chronometer or others on the same principle.

There have been several contrivances for *remontoire* escapements; but there are defects in all of them; and there is not the same advantage to be obtained by giving the impulse to a watch-balance by means of some other spring instead of the mainspring as there is in turret-clocks, where the force of the train is liable to very much greater variations than in chronometers or small clocks.

Tourbillon escapements, and a few other things not necessary to notice here, are described in the 7th edition of Sir E. Beckett's (now Lord Grimthorpe) *Rudimentary Treatise on Clocks, Watches, and Bells.*

Repeaters, Keyless Watches, etc.—Repeating watches, *i.e.*, watches which strike the hours and quarters on pushing in the handle, are now scarcely ever made in England, and with very good reason, for it is almost impossible to crowd into the space of even a large-sized watch the quantity of wheels and other things required for the repeating work without unduly interfering with the going part, and, besides that, the striking work itself is very liable to get out of order.

The winding of watches without a key is an object for which there have been several inventions, and it possesses a considerable advantage, besides the mere convenience of being independent of a key, for, as there is no occasion to open it, the case may be made to fit more closely, and the air is more completely excluded and consequently the watch will go longer without cleaning; and it also saves the thickness and the cost of a double back to the case. The first plan of the kind was that of pulling out the knob of the handle, which went into the watch, and had a gathering click attached to it which wound up the fusee, or the barrel, by means of a ratchet. But this was not found to answer: it was liable to get out of order; and, moreover, at every time of winding fresh air was pumped into the watch, which soon produced injurious effects. A far better plan is that of combining the two objects of winding and setting the hands by means of the handle, in the manner we shall now describe. In Fig. 12 *d* is a wheel on the barrel, with bevelled teeth, and there is another small bevelled wheel on a spindle *b*, which ends in a milled head *a*, within the handle or pendant; these two wheels cannot conveniently be arranged so as to work into each other without the intervention of a third between them, which is marked *e* in the left-hand section. It is easy to see that turning the milled head will wind up the barrel. The same arrangement might of course be applied to the fusee, though it would increase the size; but in fact these watches are made without one, and the practice is increasing. The winding wheel *d* is also made with the well-known contrivance of Breguet, known by the name of the "tipsy key" when applied to a common winding key, which enables you to turn the handle the wrong way without doing anything except moving a ratchet-wheel over its click, and consequently without straining the watch in attempting to wind it the wrong way. The same handle and wheels are also made use of to set the hands, thus: there is a small wheel *f* which turns on a stud at the end of the lever *fgh*, and as the lever turns on a pivot at *g*, when its end *h*, which just projects through the rim of the watch, is pushed on one side, the wheel *f* will then be thrown into gear with the winding wheel *d* and the hour pinion in the middle of the watch; and consequently, if the handle is then turned, it will alter the hands, just as they are usually altered from the back by a key in foreign watches, so that the face need never be opened. Of course, while this is doing, you do at the same time wind up the watch a little if the hand has to be turned the way for winding; but that is of no consequence, except that you cannot put the hands forward immediately after you have completely wound up the watch. There are various other arrangements for winding and setting by the handle substantially on the same principle. The ring is difficult to fix firmly when flexible on a stud perforated for the winding arbor, as no screw can go through it. The ring and the stud should be made in one piece. There is no use in it being hinged, as usual.

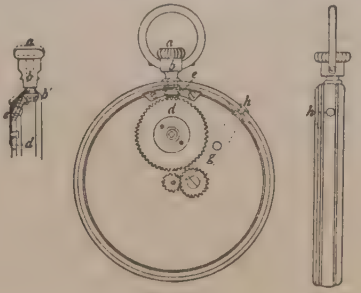

FIG. 12.

In the chronograph watch there is, in addition to the centre seconds-hand, an independent seconds-hand which, when not in operation, stands at zero. Pressure on the crown-piece acts successively (1) on a starting motion, (2) on a stopping motion, and (3) on a motion which sends the hand back by the shortest path to zero.

Watches are also made with what are called *split seconds-hands*,—the two hands being in their ordinary state together and appearing as one, but when you push in a knob one of them is stopped, while the other goes on; the time shown by the stopped one is of course the time of the observation. Sometimes this is done by merely connecting the hands by a very slight spiral spring, which will allow itself to be untwisted one or two coils without stopping the watch; and, as it cannot be of any use to stop the seconds-hand longer than a minute, this seems to answer. There is, however, another plan, in which these two hands, or at least the socket of one and the arbor of the other, are connected by a pair of disks set obliquely on the arbor and the socket respectively, so that, whenever the spring which keeps them together is allowed to act, it brings the loose hand up to the hand fixed on the arbor; and it does not signify how long it may be stopped by throwing the disks out of contact. One of the disks is heart-shaped, and is connected with the other by a spring, forming what is called a *jumper*.

For the use of electrical engineers and others who are brought within the influence of powerful electrical machinery, it has been found necessary to introduce non-magnetizable watches. At present this is best secured by making the balance of silver or platinum alloy, and the balance spring of gold or palladium. The use of steel in moving parts of the works is carefully avoided, and thus fairly good timekeepers indifferent to magnetic influences are produced.

The introduction of machinery for the manufacture of watch movements has had the effect of greatly cheapening the commoner class of watches, and yet supplying a fairly satisfactory timekeeper. It is in America that the application of machinery to watchmaking has found its greatest development, and its success has enabled the American manufacturers to obtain considerable foothold in the European market for cheap watches. But watch movements are also now very extensively made by machinery in Birmingham, Coventry, and several Lancashire towns.

Under the auspices of the Royal Society a department has been established at Kew observatory for the testing and certifying of watches in respect of their compensation for variations of temperature, and their uniformity of motion in different positions. Watches which obtain certificates of the first class have also awarded to them merit marks up to 40 for complete absence of variation in daily rate, 40 for absolute freedom from change of rate in different positions, and 20 for perfect compensation for variations of temperature. The testing establishment has only been instituted for a few years; but its services are being largely sought by manufacturers of the high class of watches, who have labored with equal zeal and success to keep the English-made watch unapproached by the product of any other nation. (G.)

WATER,[1] as everybody knows, is a generic term which includes a great variety of different substances. But when we compare any two species we always find more of agreement than of difference in properties which suggest that all waters consist essentially of the same thing, which is only modified differently in the several varieties by the nature or proportion of impurities. This surmise is confirmed by the results of scientific inquiry. In all ordinary waters, such as are used for primary purposes, the impurities amount to very little by weight—as a rule to less than $\frac{1}{10}$th of 1 per cent.

Of all natural stores of water the *ocean* is by far the most abundant, and from it all other water may be said to be derived. From the surface of the ocean a continuous stream of vapor is rising up into the atmosphere to be recondensed in colder regions and precipitated as rain, snow, or sleet, etc. Some $\frac{8}{11}$ths of these precipitates of course return directly to the ocean; the rest, falling on land, collects into pools, lakes, rivers, etc., or else penetrates into the earth, perhaps to come to light again, or to be brought to light, as springs or wells.

As all the saline components of the ocean are non-volatile, rain-water, in its natural state, can be contaminated only with atmospheric gases—oxygen, nitrogen, and carbonic acid. So we should presume, and so it is, except that these gases, having different rates of solubility, are not associated in rain-water (or natural water generally) in the proportions characteristic of their source. Thus, for instance, while atmospheric air contains 21 per cent. by volume of oxygen, a solution of air in water contains about 34.0 per cent. of that gas. Besides, rain-water, for the reason stated, contains perceptible traces of ammonia, combined as a rule, at least partly, with nitric acid, which latter is being produced wherever an electric discharge pervades the atmosphere. This electrically-produced nitrate of ammonia forms no doubt the primary source of all organic nitrogen.

Lake waters, as a class, are relatively pure, especially so if the mountain slopes over which the rain collects into a lake are relatively free of soluble components. As an example we may refer to the water of Loch Katrine (Scotland), which is almost chemically pure, apart from small, but perceptible, traces of richly carboniferous matter taken up from the peat of the surrounding hills, which impart to it a faint brownish hue, while really pure water is blue.

River water varies very much in composition even in the same bed, as a river in the course of its journey towards the ocean passes from one kind of earth to others; while, compared with spring-waters, relatively poor in dissolved salts, rivers are liable to be contaminated with more or less of suspended matter.

Spring waters, having been filtered through more or less considerable strata of earth, are, as a class, clear of suspended, but rich in dissolved, mineral matter. Of ordinarily occurring minerals only a few are perceptibly soluble in water, and of these carbonate of lime, sulphate of lime, and common salt are most widely diffused. Common salt, however, in its natural occurrence, is very much localized; and so it comes that spring and well waters are contaminated *chiefly* with carbonate and sulphate of lime. Of these two salts, however, the former is held in solution only by the carbonic acid of the water, as bicarbonate of lime. But a carbonate-of-lime water, if exposed to the atmosphere, even at ordinary temperatures, loses its carbonic acid, and the carbonate of lime crystallizes out. The fantastically shaped "stalactites" which adorn the roofs and sides of certain caverns are produced in this manner.

In the relatively rare cases where a spring water in the course of its migrations meets with a deposit of common salt or other soluble salts, it dissolves more or less of these and becomes a salt-water. Most salt-waters are substantially solutions of common salt (chloride of sodium), associated with only little of salts of potash and magnesia. But there are exceptions; in the so-called "bitter waters" the dissolved matter consists chiefly of sulphate of magnesia and other magnesia salts.

Immense quantities of carbonic acid gas are being constantly produced in the interior of the earth, probably by the action, at high temperatures, of steam on the carbonates of lime and magnesia. Some of it collects and is stored up temporarily in cavities, but the bulk streams out into the atmosphere, invisibly as a rule, through what one might call the capillaries of the earth's body; but here and there it unites into veins and arteries, and comes forth, it may be, as a mighty carbonic acid spring. Carbonic acid being one and a half times as heavy as atmospheric air, it may collect into pools or even lakes; the "Dog's Grotto," near Naples, and the "Valley of Death," in Asia Minor, are illustrative examples; but, carbonic acid being a gas, and consequently diffusible, such lakes can maintain their level only if there is a constant and abundant supply of the gas from below.

A far more frequent occurrence is that a mass of water and a mass of carbonic acid meet within the earth. As a rule, the pressure on the gas is more than one atmosphere, and the supply of the gas is abundant. The water then takes up considerably more carbonic acid than it would under ordinary atmospheric pressure, and if an outlet be provided, perhaps artificially by a boring, a frothy mass of carbonic acid water comes forth as a fountain, sometimes of great volume. Such carbonic acid waters are met with in many parts of the world,—chiefly, however, in Germany. The well-known Apollinaris water is an example. In this connection we may refer also to the *soffioni* of Tuscany—jets of steam charged with ammonia or vapor of boric acid, which condense in the air and collect into "lagoons" of (substantially) a very dilute solution of boric acid. Boric acid waters, however, appear to be entirely confined to a limited district in Tuscany to the south of Volterra.

In addition to its natural components, water is liable to be contaminated through accidental influxes of foreign matter. Thus, for instance, all the Scottish Highland lochs are brown through the presence in them of dissolved peaty matter. Rivers flowing through, or wells sunk in, populous districts may be contaminated with excrementitious matter, discharges from industrial establishments, etc. Our instinct rebels against the drinking of a contaminated water, and it guides us correctly. Not that those organic compounds are in themselves hurtful. An otherwise pure water, contaminated with, say, one ten thousandth of its volume of urine, might be drunk with perfect confidence. Yet the presence of especially nitrogenous organic matter is a serious source of danger, inasmuch as such matter forms the natural food or soil for the development of micro-organisms, including those kinds of bacteria which are now supposed to propagate infectious diseases. Happily nature has provided a remedy. The nitrogenous organic matter, dissolved in (say) a river speedily suffers disintegration by the action of certain kinds of bacteria, with formation of ammonia and other (harmless) products of simple constitution; and the ammonia, again, is no sooner formed than, by the conjoint action of other bacteria and atmospheric oxygen, it passes first into (salts of) nitrous and then nitric acid. A water which contains combined nitrogen in the form of nitrates only is, as a rule, safe organically; if nitrites are present it becomes liable to suspicion; the presence of ammonia is a worse symptom; and if actual nitrogenous organic matter is found in more than microscopic traces the water is possibly (not necessarily) a dangerous water to drink.

---

[1] Compare CHEMISTRY, vol. v. pp. 418–420, and SEA WATER.

Wanklyn's method of water analysis is based upon these ideas. Starting with half a litre of the water, he distils it with a small quantity of carbonate of soda, and in the distillate determines the ammonia colorimetrically with Nessler's reagent (see MERCURY, vol. xvi. p. 39.) When all the saline ammonia (the *free* ammonia) is thus eliminated, alkaline permanganate of potash is added to the residue and the distillation resumed. Part of the nitrogen of the organic matter is eliminated as ammonia; it is determined in the distillate, by Nessler's reagent, and reported as *albumenoid* ammonia. The results are customarily referred to one million parts of water analyzed. To give an idea of the order of quantities here dealt with, let us say that a water yielding 0.1 part of free and 0.1 part of albumenoid ammonia would be condemned by any chemist, as possibly dangerous. The peaty waters of the Scottish Highlands, however, contain much of both ammonias, and yet are drunk by the natives with perfect impunity.

All waters, unless very impure, become safe by boiling, which process kills any bacteria or germs that may be present.

Of the ordinary saline components of waters, soluble magnesia and lime salts are the only ones which are objectionable sanitarily if present in relatively large proportion. Carbonate of lime is harmless; but, on the other hand, the widely diffused notion that the presence of this component adds to the value of a water as a drinking water is a mistake. The farinaceous part of food alone is sufficient to supply all the lime the body needs; besides, it is questionable whether lime introduced in any other form than that of phosphate is available for the formation of, for instance, bone tissue.

The fitness of a water for washing is determined by its degree of softness. A water which contains lime or magnesia salts decomposes soap with formation of insoluble lime or magnesia salts of the fatty acids of the soap used. So much of the soap is simply wasted; only the surplus can effect any cleansing action. An excellent and easy method for the determination of the hardness of a water has been devised by Clark. A measured volume of the water is placed in a stoppered bottle, and a standard solution of soap is then dropped in from a graduated vessel, until the mixture, by addition of the last drop of soap, has acquired the property of throwing up a peculiar kind of creamy froth when violently shaken, which shows that all the soap-destroying components have been precipitated. The volume of soap required measures the hardness of the water. The soap-solution is referred to a standard by means of a water of a known degree of hardness prepared from a known weight of carbonate of lime by converting it into neutral chloride of calcium, dissolving this in water and diluting to a certain volume. A water is said to have "1, 2, 3, . . . *n* degrees of hardness," if it is equivalent in soap-destroying power to a solution of carbonate of lime containing 1, 2, 3, . . . *n* grains of this salt per imperial gallon.

That part of the hardness of a water which is actually owing to carbonate of lime (or magnesia) can easily be removed in two ways. (1) By boiling, the free carbonic acid goes off with the steam, and the carbonate of lime, being bereft of its solvent, comes down as a precipitate which can be removed by filtration, or by allowing it to settle, and decanting off the clear supernatant liquor. (2) A method of Clark's is to mix the water with just enough of milk of lime to convert the free carbonic acid into carbonate. Both this and the original carbonate of lime are precipitated, and can be removed as in the first case. See p. 431 *infra.*

From any uncontaminated natural water pure water is easily prepared. The dissolved salts are removed by distillation; if care be taken that the steam to be condensed is dry, and if its condensation be effected within a tube made of a suitable metal (platinum or silver are best, but copper or block tin work well enough for ordinary purposes), the distillate can contain no impurities except atmospheric gases, which latter, if necessary, must be removed by boiling the distilled water in a narrow-necked flask until it begins to "bump," and then allowing it to cool in the absence of air. This latter operation ought, strictly speaking, to be performed in a silver or platinum flask, as glass is appreciably attacked by hot water. For most purposes distilled water, taken as it comes from the condenser, is sufficiently pure.

Pure water, being so easily procured in any quantity, is used largely as a standard of reference in metrology and in the quantitative definition of physical properties. Thus a "gallon" is defined as the volume at 62° F. of a quantity of water whose uncorrected mass, as determined by weighing in air of 30-inch pressure and 62° F. of temperature, is equal to 10 ℔ avoirdupois. The kilogramme in like manner is the mass of 1 cubic decimetre of water, measured at the temperature corresponding to its maximum density (4° C.). The two fixed points of the thermometer correspond—the lower (0° C. or 32° F.) to the temperature at which ice melts, the upper (100° C. or 212° F.) to that at which the maximum tension of steam, as it rises from boiling water, is equal to 760 mm. or 30-inch mercury pressure. 30 inches being a little more than 760 mm., 212° F. is, strictly speaking, a higher temperature than 100° C., but the difference is very trifling. Specific heats are customarily measured by that of water, which is taken as $=1$. All other specific heats of liquids or solids (with one solitary exception, formed by a certain strength of aqueous methyl alcohol) are less than 1. The temperate character of insular climates is greatly owing to this property of water. Another physiographically important peculiarity of water is that it expands on freezing (into ice), while most other liquids do the reverse. 11 volumes of ice fuse into only 10 volumes of water at 0° C.; and the ice-water produced, when brought up gradually to higher and higher temperatures, again exhibits the very exceptional property that it contracts between 0° and 4° C. (by about $\frac{1}{10000}$ of its volume) and then expands again by more and more per degree of increase of temperature, so that the volume at 100° C. is 1.043 times that at 4° C. Imagine two lakes, one containing ordinary water and another containing a liquid which differs from water only in this that it has no maximum density. Imagine both to be, say, at 5° C., and cold winter weather to set in. Both lakes become colder, being cooled down by convection until they are at 4° C. The imaginary lake then continues losing heat in the same way; in the real lake the colder water floats on the surface and the underlying mass of water can lose heat only by the slow process of conduction. The real lake retains its heat more tenaciously, but for the reason stated will draw a sheet of ice, while the imaginary lake is still on its way to 0° C. The latter, indeed, if the winter is short, may fail to freeze altogether, while the former does freeze superficially. In either the freezing is a slow process, because for every pound of ice produced 80 pound-centigrade units of heat are set free. Let us now assume that, after even the imaginary lake had drawn a sheet of ice, warm weather sets in. In either case a layer of liquid water of 0° C. is formed on the ice, and through it the heat from the air travels, in the imaginary case by slow conduction, in the real case by quick convection. The real ice is the first to disappear, and the upper strata of relatively cold water will soon come up to 4° C. by the prompt effect of convection, while in the case of the imaginary lake it takes a far longer time before all the mass has come up to 4° C. by conduction. From 4° C. upwards, heat is taken in at the same rate on both sides.

In former times water was viewed as an "element," and the notion remained in force after this term (about the time of Boyle) had assumed its present meaning, although cases of decomposition of water were familiar to chemists. In Boyle's time it was already well known that iron, tin, and zinc dissolve in aqueous muriatic acid or vitriol with evolution of a stinking inflammable gas. Even Boyle, however, took this gas to be ordinary air contaminated with inflammable stinking oils. This view was held by all chemists until Cavendish, before 1784, showed that the gas referred to, if properly purified, is free of smell and constant in its properties, which are widely different from those of air—the most important point of difference being that the gas when kindled in air burns with evolution of much heat and formation of water. Cavendish, however, did not satisfy himself with merely proving this fact qualitatively; he determined the quantitative relations, and found that it takes very nearly 1000 volumes of air to burn 423 volumes of "hydrogen" gas; but 1000 volumes of air, again according to Cavendish, contain 210 volumes of oxygen; hence, very nearly, 2 volumes of hydrogen take up 1 volume of oxygen to become water. This important discovery was only confirmed by the subsequent experiments of Humboldt and Gay-Lussac, which were no more competent than Cavendish's to prove that the surplus of 3 units (423 volumes instead of 420) of hydrogen was an observational error.

(W. D.)

WATERBURY, a city in Newhaven county, Connecticut, United States, is situated on the Naugatuck river, 77 miles northeast of New York, at the junction of three railroads connecting it with Bridgeport, Hartford, and Meriden. It was settled by colonists from Hartford in 1677, and bore at first the Indian name of Mattatuck. The land, rocky and hilly, was poor for farming, and the inhabitants began to turn to manufacturing pursuits, in a humble way, before 1800. But the growth in population and business was very slow, till the civil war created such a demand for brass and manufactured articles of that metal that the small factories rapidly grew in number and size, and Waterbury has now become the centre of the brass industry in the United States. Its factories represent an outlay of 10 million dollars, and turn out a great quantity of sheet brass and copper, wire, and tubing, with a multitude of small articles—clocks, watches, lamps, pins, silver-plated ware, etc. The population, which is largely German and Irish, was 17,806 in 1880, and is now (1888) believed to approach 27,000. The city is well lighted by electric lights, and supplied with pure water from a spring-fed reservoir 6 miles distant. A free loan and reference library, founded in 1868, contains 42,000 volumes. Waterbury was incorporated as a city in 1853.

WATERFORD, a maritime county of Ireland, in the province of Munster, is bounded E. by Waterford Harbor, separating it from Wexford, N. by Kilkenny and by Tipperary, W. by Cork, and S. by the Atlantic. Its greatest length from east to west is 52 miles, and its greatest breadth from north to south is 28 miles. The total area is 461,552 acres, or about 721 square miles. The coast-line is in some parts bold and rocky, and is indented by numerous bays and inlets, the principal being Waterford Harbor; Tramore Bay, with picturesque cliffs and some extensive caves, and noted for its shipwrecks, on account of the rocky character of its bed; Dungarvan Harbor, much frequented for refuge in stormy weather; and Youghal Harbor, partly separating county Waterford from county Cork. The surface of the county is to a large extent mountainous, especially towards the west and northwest, consisting chiefly of metamorphosed Lower Silurian rocks, the valleys being occupied by Carboniferous Limestone. There is also evidence on an extensive scale of former glacial action. The Knockmealdown Mountains, which attain a height of 2609 feet, form the northern boundary with Tipperary. A wide extent of country between Clonmel and Dungarvan is occupied by the two ranges of the Commeragh and Monavallagh Mountains, reaching in Knockanarian a height of 2478 feet. To the south of Dungarvan there is a lower but very rugged range, called the Drum Hills. The southeastern division of the county is for the most part level, consisting chiefly of clay slate interrupted by patches of primitive limestone, and also by conglomerate and basalt, forming in some parts of the coast lofty columnar cliffs. Coal and iron were formerly wrought, but the only mineral product now of importance is copper, the mines at Knockmahon ranking next in Ireland to those at Berehaven. Lead mining, formerly prosecuted with some success, has now practically ceased. Lime is abundant, and coralline sea-sand is obtained. Slate is quarried in considerable quantities at Lismore, and there are also quarries of valuable sandstone and of marble. Ochres and clays for the manufacture of earthenware are also obtained. Though Waterford has benefited in its communications by the important rivers in its vicinity, the only large river it can properly claim as belonging to it is the Blackwater. This enters the county to the east of Fermoy, and flows eastward along a trough of Carboniferous Limestone to Cappoquin, where it turns abruptly southwards, to fall into the sea at Youghal Harbor. At its junction with the Bride below Cappoquin it is navigable for vessels of 100 tons burden. Waterford Harbor may be called the estuary of three important rivers, the Suir, the Nore, and the Barrow, but neither of the last two touches the county. The Suir reaches it at its union with the Nier about 8 miles from Clonmel, and thence forms its northern boundary with Tipperary and Kilkenny. It is navigable for vessels of 800 tons burden to Waterford, for barques and large lighters to Carrick-on-Suir, and for boats of 50 tons to Clonmel.

Agriculture.—The land is generally better adapted for pasturage than for tillage, although there are considerable tracts of rich soil in the southeastern districts. The total number of holdings in 1886 was 10,188, of which 26 were above 500 acres in extent, 1029 between 100 and 500 acres, 1660 between 50 and 100 acres, 2726 between 15 and 50 acres, 2530 between 1 and 15 acres, and 2217 did not exceed 1 acre. Out of a total of 456,198 acres only 83,968 acres, or 18.4 per cent., were under crops; 235,801 acres, or 51.7 per cent., were under grass; 330 acres fallow; 19,317 acres, or 4.2 per cent., woods and plantations; 22,791 acres, or 5.0 per cent., bog and marsh; 76,137 acres, or 16.7 per cent., barren mountain land; and 17,854, or 3.9 per cent., water, roads, fences, etc. Since 1859 the area under crops has decreased nearly a third, the amount in that year being 116,940 acres. Corn crops occupied 59,848 acres in 1859 and only 35,461 in 1886, the areas under wheat in these years being respectively 23,671 and 1326 acres, under oats 32,526 and 32,795 acres, and under barley, bere, etc., 3651 and 1340 acres. The area under green crops in 1859 was 38,213 acres, and in 1886 it was 24,436 acres, the areas under potatoes in these years being respectively 23,385 and 14,361 acres, under turnips 10,886 and 6171 acres, and under other green crops 4042 and 3904 acres. Horses between 1859 and 1886 diminished from 14,184 to 12,794 of which 9122 were two years old and upwards, but cattle increased from 84,440 to102,878 of which 39,428 were milch cows, and sheep from 42,408 to 55,805, while pigs decreased from 55,701 to 44,510. The number of mules in 1886 was 942, of asses 4319, of goats 5510, and of poultry 258,058.

In 1876, according to the *Return of Owners of Land*, Waterford was divided among 814 proprietors, possessing 454,937 acres at an annual valuation of £276,642 ($1,344,480.12), or an average of about 12s. 2d. ($2.94) per acre. The estimated extent of waste lands was 880 acres. Of the owners 600 possessed one acre and upwards. The number of large estates is exceptionally great. The following possessed upwards of 8000 acres: marquis of Waterford, 39,884; Lord Stuart de Decies, 30,823; duke of Devonshire, 27,484; R.A. Chearnley, 18,166; Edmond De La Poer, 13,448; John Palisser, 9825; Lord Ashtown, 9435; Sir J. H. Keane, Bart., 8909; and Sir R. J. Musgrave, Bart., 8282.

Manufactures and Trade.—The woollen manufacture, except for private use, is now pratically extinct, but the cotton manufacture is still of some importance. There are also breweries, distilleries, and a large number of flour-mills. Sea-fishing is prosecuted chiefly at Dungarvan. There are valuable salmon fisheries on the Blackwater and the Suir.

Railways.—From the city of Waterford the Waterford and Central Ireland line goes northwards by Kilkenny, the Waterford and Limerick by Carrick-on-Suir and Cloumel to Limerick, the Waterford and Tramore to Tramore, and the Waterford, Dungarvan, and Lismore to Lismore, where it joins a branch of the Great Southwestern.

Administration and Population.—From 119,457 in 1812 the population increased by 1841 to 196,187, but by 1861 it diminished to 134,252, by 1871 to 123,310, and by 1881 to 112,768 (males 54,618, females 58,150), or 8.5 per cent. less than in 1871. The total number of emigrants from 1st May, 1857, to 31st December, 1878, was 67,080, and to 31st December, 1885, it was 79,240. In 1880 the number reached 2675, and in 1885 it was 1333. The county is divided into 8 baronies, with 82 parishes and 1557 town-lands. The principal towns are Waterford (population 29,181), Dungarvan (6306), Tramore (2036), Portlaw (1891), and Lismore (1860). Before the Redistribution Act of 1885 the county returned two members of parliament, the borough of Waterford two, and Dungarvan one,—Clonmel, which is partly in Waterford, also returning one. The county now returns two members, for the East and West Divisions respectively, while the county of the city of Waterford returns one member, and Dungarvan and Clonmel have been disfranchised. It is in the Leinster circuit, and assizes are held at Waterford, and quarter sessions at Lismore, Dungarvan, and Waterford. It is in the Cork military district, and there is a brigade depot at Clonmel, and barrack stations at Dungarvan and Waterford. The Catholics formed 94.8 per cent. of the population in 1871 and 95.0 in 1881, the Episcopalians in the same years 4.1 per cent. The proportion of persons who could read and write in 1871 was 35.7 per cent., and in 1881 it was 45.8; in 1881 10.6 per cent. could read but could not write, and 43.6 could neither read nor write,—14.3 per cent. being under seven years of age.

History and Antiquities.—In the 9th century the Danes landed in the district, and afterwards made a permanent settlement there. There are in the county a considerable number of barrows, duns, cromlechs, and similar relics of the ancient inhabitants. At Ardmore there is a round tower 97 feet in height, and near it a huge rath and a large number of circular entrenchments. Waterford was one of the twelve counties into which King John, in 1205, divided that part of Ireland which he nominally annexed to the English crown. On account of the convenience of the city as a landing place, many subsequent expeditions passed through the county directed against disaffected or rebellious tribes. In 1444 the greater part of it was granted to James, earl of Desmond, and in 1447 it was bestowed on John Talbot, earl of Shrewsbury, who was created earl of Waterford. The county suffered severely during the Desmond rebellion, in the reign of Elizabeth, as well as in the rebellion of 1641 and during the Cromwellian period. Among the old castles special mention may be made of Lismore, originally erected by John, afterwards king of England, in 1185, but now in great part comparatively modern. The chief ecclesiastical remains are those of the chancel and nave of the cathedral of Ardmore, where a monastery and oratory were founded by St. Declan in the 7th century. The see of Ardmore was abolished in the 12th century.

WATERFORD, a city, county of a city, municipal and parliamentary borough, and the chief town of the above county, is finely situated on the south bank of the Suir 4 miles above its junction with the Barrow, at the head of the tidal estuary called Waterford Harbor, and on several railway lines, which afford it convenient communication with all parts of Ireland. It is 32 miles west of Wexford, 76 northeast of Cork, and 97 south-southwest of Dublin. The Suir is crossed by a wooden bridge of thirty-nine arches, and 832 feet long, connecting Waterford with the suburb of Ferrybank. The town is built chiefly along the banks of the river, occupying for the most part low and level ground except at its western extremity. The modern Protestant cathedral of the Holy Trinity, generally called Christ Church, a plain structure with a lofty spire, occupies the site of the church built by the Danes in 1096. Near it are the episcopal palace and deanery. There is a handsome Catholic cathedral, erected at a cost of £20,000 ($97,200); and the training seminary for priests called St. John's college deserves notice. The principal secular buildings are the town-hall, the county and city courts and prisons, the new custom-house, erected in 1876, at a cost of £9000 ($43,740), the barracks, and the union workhouse. At the extremity of the quay is a large circular tower, called Reginald's Tower, forming at one time a portion of the city walls, and occupying the site of the tower built by Reginald the Dane in 1003. Near the summit one of the balls shot from the cannon of Cromwell while besieging the city is still embedded in the wall. There are a number of hospitals and similar benevolent institutions, including the leper house founded in the reign of King John, now possessing an income of £1000 ($4860) a year, and made use of practically as an infirmary. The town possesses breweries, salt-houses, foundries, and flour-mills; and there is a large export trade in cattle, sheep, and pigs, and in agricultural produce. The population of the city (area 10,059 acres) in 1871 was 29,979, and in 1881 it was 29,181.

Waterford Harbor is a winding and well-sheltered bay, formed by the estuary of the river Suir, and afterwards by the joint estuary of the Nore and Barrow. Its length to the sea is about 15 miles. Its entrance is about 2½ miles wide and is well lighted by a fixed bright light on the ancient donjon of Hook Tower (139 feet in height), by a red light on Dunmore pier, and by two leading lights at Duncannon. The quay, at which vessels of 2000 tons burden can discharge, was enlarged in 1705 by the removal of the city walls, and is about 1¼ miles in length. At Ferrybank on the Kilkenny side of the river, there is a shipbuilding yard with patent slip and graving dock. By the Suir there is navigation for barges to Clonmel, by the Barrow for sailing vessels to New Ross and thence for barges to Athy, and by the Nore for barges to Inistiogue. The total number of vessels connected with the port in 1885 was 33, of 5246 tons. The number of British and foreign vessels that entered the port in the same year was 1784 of 530,092 tons, while 1255 of 412,326 tons cleared.

Anciently Waterford was called *Cuan-na-groith*, the haven of the sun. By early writers it was named Menapia. It is supposed to have existed in very early times, but first acquired importance under the Danes, of whom it remained one of the principal strongholds until its capture by Strongbow in 1171. On 18th October, 1172, Henry II. landed near Waterford, and he here received the hostages of the people of Munster. It became a cathedral city in 1096. Prince John, afterwards king of England, who had been declared lord of Ireland in 1177, landed at Waterford in 1185. After ascending the English throne he in 1204 granted it a fair, and in 1206 a charter of incorporation. He landed at Waterford in 1210, in order to establish within his nominal territories in Ireland a more distinct form of government. The city received a new charter from Henry III. in 1232. Richard II. landed at Waterford in October, 1394, and again in 1399. In 1447 it was granted by Henry VI. to John Talbot, earl of Shrewsbury, who was created earl of Waterford. In 1497 it successfully resisted an attempt of Perkin Warbeck to capture it, in recognition of which it received various privileges from Henry VII., who gave it the title of *urbs intacta*. In 1603, after the accession of James I. to the English crown, the city, along with Cork, took a prominent part in opposition to the Government and to the Protestant religion, but on the approach of Mountjoy it formally submitted. From this time, however, the magistrates whom it elected refused to take the oath of supremacy, and, as by its charter it possessed the right to refuse admission to the king's judges, and therefore to dispense with the right of holding assizes, a rule was obtained in the Irish chancery for the seizure of its charter, which was carried into effect in 1618. In 1619 an attempt was made to induce Bristol merchants to settle in the city and undertake its government, but no one would respond to the invitation, and in 1626 the charter was restored. The city was unsuccessfully attacked by Cromwell in 1649, but surrendered to Ireton 10th August, 1650. After the battle of the Boyne James II. embarked at it for France (July, 1690). Shortly afterwards it surrendered to William, who sailed from it to England. It sent two members to parliament from 1374 to 1885, when the number was reduced to one.

WATER-GLASS. See Silica, vol. xxii. p. 59.

WATER-HEN. See Moor-Hen.

WATER-LILY, a somewhat vague term, given to almost any floating plant with conspicuous flowers, but applying more especially to the species of *Nymphœa* and *Nuphar*. These are aquatic plants with their thick fleshy rootstocks or tubers embedded in the mud, and throwing up to the surface circular shield-like leaves, and leafless flower-stalks, each terminated by a single flower, often of great beauty, and consisting of four or five sepals, and numerous petals gradually passing into the very numerous hypogynous or perigynous stamens without any definite line of demarcation between them. The ovary consists of numerous carpels united together and free, or more or less embedded in the top of the flower-stalk. The ovary has many cavities with a large number of ovules attached to its walls, and is surmounted by a flat stigma of many radiating rows as in a poppy. The fruit is baccate, and the seeds are remarkable for having their embryo surrounded by an endosperm as well as by a perisperm. The anatomical construction of these plants presents many peculiarities which have given rise to discussion as to the allocation of the order among the dicotyledons or among the monocotyledons, the general balance of opinion being in favor of the former view. The leaf-stalks and flower-stalks are traversed by longitudinal air-passages, whose disposition varies in different species. These species of *Nymphæa* are found in every quarter of the globe. Their flowers range from white to rose-colored yellow, and blue. Some expand in the evening only, others close soon after noon. *Nymphæa alba* is common in some parts of Britain, as is also the yellow *Nuphar luteum*. The seeds and the rhizomes contain an abundance of starch, which renders them serviceable in some places for food.

Under the general head of water-lily are included the lotus of Egypt, *Nymphæa Lotus*, and the sacred lotus of India and China, *Nelumbium speciosum*, formerly a native of the Nile, as shown by Egyptian sculptors and other evidence, but no longer found in that river. The gigantic *Victoria regia*, a native of tropical South America, also belongs to this group.

WATERLOO, a village of Belgium, in the province of Brabant, 9½ miles to the south-southeast of Brussels, was the headquarters of the duke of Wellington from 17th to 19th June, 1815, and has given its name throughout the English-speaking world to the famous battle fought in its neighborhood on June 18, 1815. See NAPOLEON, vol. xvii. pp. 230–31.

WATERLOO, a city and the county seat of Black Hawk county, Iowa, United States, is situated in a rich farming and stock-raising country, on both sides of the Cedar river, which here furnishes a valuable water power. The population in 1885 was 6479, of whom 1048 were foreign born.

WATERLOO-WITH-SEAFORTH, a watering-place of Lancashire, England, on the Irish Sea, at the mouth of the Mersey, nearly opposite New Brighton in Cheshire, and on the Liverpool, Crosby, and Southport Railway, 4 miles north by west of Liverpool. On account of its facilities for bathing, firm sands, pleasant scenery, and nearness to Liverpool, of which indeed it may now be considered a suburb, it is much frequented during the summer months. It is well and regularly built, and possesses the usual characteristics of a rising watering-place. The population of the urban sanitary district (area 740 acres) was 9118 in 1881.

WATERPROOF. See INDIA-RUBBER, vol. xii. p. 883.

WATERSPOUT. See METEOROLOGY, vol. xvi. pp. 134–36.

WATER-SUPPLY. An ample supply of pure water is of the utmost importance for the healthiness of towns. When the population of a district is scattered it is possible to supply individual wants by means of streams, springs, or shallow wells; but when a number of people are congregated within the limited area of a town the natural supply of water in this area is liable to be insufficient, and is also in danger of being contaminated by sewage and house refuse. Accordingly, works for the collection, storage, purification, and distribution of water are indispensable necessities in towns, for the preservation of health and the promotion of cleanliness. The remains of aqueducts near Rome and at other places (see AQUEDUCT) show that important works for providing water were undertaken many centuries ago; and water for irrigation and other purposes has for ages been stored, in the rainy season, in tanks by the natives of India. Artificial provisions for the supply of water were, however, entirely neglected in Europe during the Middle Ages, and the colossal works of earlier times were allowed to fall into decay; and most of the present systems of water-supply are of comparatively modern date.

Origin of Supply.

Rainfall.—All supplies of fresh water come primarily from the clouds, though portions may eventually be drawn from the bowels of the earth. Water when distilled is obtained in its purest form; and the heat of the sun is continually drawing up large quantities of moisture from sea and land, forming clouds which return it as rain to the earth. Some of the rain is quickly evaporated from the surface of the earth, and returned to the clouds; some sinks into the ground to feed springs and underground stores of water; and some passes into streams and rivers, whence it flows into the sea, from which the greater portion of the rain is derived. The available water-supply of any district, accordingly, principally depends on the rainfall of the locality and the extent of the gathering ground. The rainfall varies greatly in different places, and at different periods of the year (see METEOROLOGY); and, in England alone, the average annual rainfall at the Stye, the wettest part of the lake district in Cumberland, is about eight times the rainfall at Hunstanton, the driest locality in Norfolk. The rainfall, moreover, varies from year to year; and the driest years must be taken into consideration in estimating the available water-supply.

Evaporation.—The proportion of the rainfall which is actually serviceable for water-supply depends greatly upon the season of the year in which the rain falls; for evaporation is very active in the hot season, whereas in the cold season its influence is slight. Accordingly, for hydrological purposes, the year may be divided into two seasons in the latitudes of the British Isles,—the warm season extending from the beginning of May to the end of October, and the cold season, embracing the other half of the year. Comparatively little effect is produced by variations in the amount of rain in the warm season, except in extreme cases, owing to the large proportion drawn off by evaporation, whereas the rainfall during the cold season is of the utmost importance for replenishing the sources of supply which have been drained during the summer. The period of the year, therefore, in which the rain falls is of more consequence than the total amount in the year; and a drought is much more likely to result from a dry winter than from a dry summer. Any deficiency in the supply is generally felt towards the close of the warm season, when the reserves of water, furnished by the rains of the preceding cold season, have been reduced to their lowest level by the demands of the summer.

Other circumstances also modify the influence of evaporation. Rain descending in a heavy continuous fall, by sinking into the ground or escaping into the watercourses, is less exposed to diminution by evaporation than several separate showers of rain, equivalent in total volume, but spread over a longer period. Forests and vegetation shelter the ground from the influence of evaporation; and thereby, in spite of abstracting some of the moisture for their own requirements, they augment the proportion of available rainfall. The nature and slope of the surface stratum, moreover, notably affect the loss from evaporation. Rain falling on an impermeable stratum is almost wholly evaporated in hot weather, when the surface is flat; but it flows off from a steep slope before evaporation can produce its full effect. Rain readily sinks into a porous stratum; and when a depth of three or four feet below the surface is reached it is to a great extent withdrawn from the influence of evaporation.

Percolation.—The percolation of rain through porous strata is the origin of springs and subterranean reservoirs of water, from whence so many supplies are derived. Sand, gravel, chalk, and sandstone are very absorbent strata; whilst the oolites and other limestones are permeable to a smaller extent. The excess of rainfall over evaporation sinks into the ground till it reaches the level of saturation of the stratum by previous rainfalls, and adds to the underground supply. The water thus introduced is prevented from sinking lower down into the earth by encountering an underlying impermeable stratum; and it is hindered in flowing away to the lowest point of the outcrop of the permeable stratum by friction, which causes the surface of saturation to slope towards its outlet, the inclination varying with the head of water and the resistance offered to its flow. The amount of percolation depends upon the rainfall, the porosity of the stratum, and the extent of its exposed surface; and it varies inversely as the evaporation, being greatest in winter and during heavy long-continued rainfalls, and least in the summer and with short showers of rain.

Watercourses.—On impermeable strata, the whole of the rain not removed by evaporation finds its way into the watercourses. The streams, however, draining these strata have a very variable discharge, as they are rapidly swollen after a heavy fall of rain, and soon subside (see River Engineering), whilst in fine summer weather they are liable to be dried up. Accordingly, torrential streams, in their natural condition, are not suitable for water-supply, as they tend to fail when they are most wanted, and owing to their rapid flow they carry along a large quantity of matter in suspension. The flow of streams draining permeable strata is more regular, both on account of the smaller fall generally of the river-bed, and also owing to the rainfall being delayed by percolation in its passage to the river. Some of the rain sinking into a permeable stratum tends to find an outlet outside the valley in which it falls, but most of it reappears again in the form of springs which feed the river gradually at a lower part of its course; and the loss which may occur is more than compensated for by the greater regularity of flow. In olden times, towns, villages and monasteries were established on the banks of these streams, owing to the ready, ample, and never-failing water-supply thus ensured.

Sources of Supply.

Tanks.—The simplest method of procuring pure water is to collect the rain as it falls from the clouds; and this method is a necessity where, as in tropical countries, there is an excessive rainfall during one period of the year, followed by a long drought, unless the rain sinks into a permeable stratum whence it can subsequently be drawn. These open tanks, however, excavated in the ground, have to be numerous, and often large in extent, to collect sufficient rain to supply the wants of the surrounding population for several months; and the water in them is subject to loss from evaporation during the dry season.

The collection of rain-water is also advantageous in the rural districts of temperate regions, especially for large institutions and isolated mansions and farms, where, by a simple arrangement of gutters and pipes, a large proportion of the rain falling on the sloping roofs can be stored in underground tanks. In large towns, the rain-water is liable to contamination by smoke, dust, and other impurities, and is only serviceable for gardens and water-closets, or where softness is of more consequence than purity.

Springs.—A very valuable source of water-supply is provided by springs. These springs appear at the lowest point S of the outcrop of a permeable stratum where it rests upon an impermeable stratum (Fig. 1); and they constitute the outflow of the rain which has percolated through that stratum. A spring depends for its supply upon the extent of the underground reservoir furnished by the permeable stratum; and its discharge is regulated by its level in relation to the line of saturation of the stratum and the resistance offered to its flow. The gathering ground of a spring consists of the portions AB, DS of the permeable stratum drained by it which are actually exposed at the surface, provided the surface slope is not very steep, and also of any impermeable surface strata BCD sloping from a higher level towards the permeable outcrop. The position of the spring is determined by the dip AS of the underlying impermeable stratum and the line of least resistance to the underground flow. When the permeable stratum covers the surface, and is of small extent, as when it forms a thin cap to a hill, an outflow only occurs after a fall of rain. Where a permeable stratum, with a limited gathering ground, has a sufficient depression at some point to cause the line of saturation to sink occasionally below the level of the outcrop, the outflowing spring is intermittent; and the time of the appearance of such springs (or bournes, as they are termed) can be accurately predicted by observing the rise of the water in the neighboring wells sunk into these permeable strata. A spring is generally clear and free from organic impurities, as particles in suspension are removed by the natural filtration, and organic matters are oxidized and eliminated in the passage of the water through the ground. The water, however, collects any soluble gases and salts which exist in the strata through which it flows; and most springs contain some inorganic compounds in solution, depending upon the nature of the strata and the distance traversed. Occasionally springs are so strongly impregnated with certain substances as to receive specific names, such as sulphuretted, chalybeate, and saline springs; but in such cases they are of more value for medicinal purposes than as sources of water-supply. The abundant springs derived from the chalk, though containing considerable quantities of carbonate of lime, are quite suitable for domestic purposes. Springs from large underground supplies possess the advantage of a fairly constant temperature, as their sources are protected from atmospheric changes; but underground waters are subject to the rise of temperature, experienced in descending below the surface of the earth, of 1° F., on the average, for each 52 feet of depth.

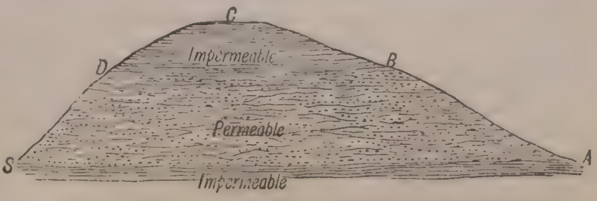

Fig. 1.

Small springs frequently supply little hamlets; and a shallow tank, formed at the spring, into which the water trickles, serves as a reservoir, which is gradually filled, and from which water is readily drawn. Large springs may afford adequate supplies for towns; but before relying upon such a source it is essential to gauge their discharge at the close of the autumn, in a dry year, so as to ascertain their sufficiency under unfavorable conditions. When springs have been selected, it only remains for the engineer to design suitable conduits for conveying the water to the place to be supplied. The fine chalk-water springs of Amwell and Chadwell, in Hertfordshire, have been thus utilized by the New River Company for supplying London, by means of a conduit 40 miles long, completed in 1613; and the springs issuing from the Malvern Hills furnish Malvern with a plentiful supply of the purest water.

Springs were naturally much prized in ancient times, when the simplest means of procuring water had to be resorted to; and ignorance of their real origin led to their being the subject of mythological legends. They were used for the supply of public fountains by the Greeks and Romans (see Fountain), and provided water for some of the Roman aqueducts.

Streams and Rivers.—In olden times, the only other obvious sources of water-supply, besides rain and springs, were the watercourses which carried off the surplus rainfall. Streams and rivers afford the most ample supply, but they become turbid in flood-time;

and when they have a rapid fall, and drain an impermeable basin, they fail in times of drought. These objections have, however, been overcome by settling-tanks, filter-beds, and storage-reservoirs,—so that now the principal supplies are drawn from these sources. The increase, indeed, of population, and especially the introduction of the system of discharging the sewerage of towns into the adjacent streams, have polluted many rivers. Fortunately, in process of time, some of the organic impurities are removed by aquatic animals and plants, and some become oxidized and thus rendered innocuous (see WATER),—so that, after a sufficient length of unpolluted flow, the river again becomes suitable for supply. The enactments against river-pollution have attacked this evil at its source; but some rivers, passing through large manufacturing centres, are hopelessly contaminated with refuse products. The best sources of water are found in streams draining uncultivated mountainous districts, where a plentiful rainfall on steep impervious strata affords a very pure though somewhat intermittent supply. The freedom from habitations, the rapid flow of rain off the surface, the absence of organic impurities and of soluble salts, prevent any chance of contamination beyond occasional discoloration by peat. Distance, however, from hilly regions and a considerable population render it frequently necessary to resort to larger rivers, which, passing towns and villages in their course, become more or less contaminated, and, being fed by springs from permeable strata, contain the salts dissolved by those springs. London, for instance, draws its principal supplies from the Thames and the Lea; and, though microscopical investigations and the reports of the water-examiners are not always reassuring about the qualities of the water thus supplied and the recuperative powers of nature, waters containing some organic matters and certain kinds of micro-organisms do not appear to be injurious, as is evidenced by the general absence of specific diseases in the inhabitants supplied from these sources.

Wells.—There are two distinct kinds of wells, namely, shallow wells, sunk into a superficial permeable stratum; and deep wells, sunk through an impermeable stratum into an underlying permeable stratum. Both kinds of wells tap the underground waters which are the sources of springs, and furnish artificial outlets for waters which would either find a natural outlet in springs at the outcrop, or which, owing to a depression of the strata, may not possess a natural outlet at a low enough level ever to drain the lower part of the underground reservoir.

Shallow wells, sunk in the ordinary manner, have long been used for collecting moderate supplies of water, where a permeable stratum, such as the Bagshot sands, or the gravel covering parts of the London basin, overlies a watertight stratum such as the London Clay, especially where a slight depression in the impervious stratum towards the centre, or a considerable expanse of the surface stratum, prevents a ready outflow from the permeable beds. Many parts of London were supplied for a long time in this manner; for the rain percolating the bed of gravel flowed into the wells sunk in it, from whence the water could be drawn up. Indeed, as pointed out by Professor Prestwich, the growth of London was restricted, till the regular establishment of waterworks, to those districts possessing a gravel subsoil, in which water could be readily procured, as no such facilities existed where the clay rose to the surface. The sites also of many of the older towns and villages were doubtless determined by similar considerations. Shallow wells are still very useful in supplying scattered populations, but they are exposed to the worst forms of contamination when the houses are near together. Any surface impurities are washed in with the rain; frequently cesspools are given an outlet into the permeable stratum from which the water-supply is derived; and pumping in the well, to increase the supply, creates a flow from the contaminated areas to the well. Such utter neglect of sanitary precautions has led to serious outbreaks of illness; and the sparkling water from some of the old wells in the City of London has proved very deleterious, from the infiltration into them of the decaying matter from graveyards and elsewhere. Shallow wells, in fact, must be resorted to with great caution, and only when an absence of habitations or a thorough inspection of the district drained by the well, affords assurance of freedom from organic pollution.

Deep wells, passing generally through impervious beds into a permeable water-bearing stratum to a depth at which an adequate supply of water is obtained, are mostly free from organic impurities, partly owing to the protection of the superincumbent impervious stratum, and partly to the filtration any impurities must undergo before reaching the well. The wells are usually formed by sinking a shaft lined with brick for the upper portion, and then carrying down a boring below to the requisite depth. The level of the water in the well depends upon the water-level in the stratum; and generally the water has to be raised by pumping to the surface. Occasionally, owing to a depression of the strata, the top of the well is below the level of the lowest part of the outcrop of the permeable stratum into which the well is sunk, and the water rises in the well directly this stratum is reached, and flows over if the hydrostatic pressure is sufficient to overcome the friction. These latter wells, known as Artesian wells, have been already described (see ARTESIAN WELLS); and the methods of boring other deep wells are precisely similar. The most favorable strata for deep wells in England are the Chalk, Oolites, New Red Sandstone, and Lower Greensand. The yield of these wells depends upon the extent of the portion of the underground reservoir which they can drain; and the reservoir depends for its supply, as in the case of springs, on the extent of the stratum exposed at the surface, the drainage it may receive from adjoining impermeable strata, and the amount of rainfall over these areas. As these points can only be roughly estimated, it is impossible to judge of the yield beforehand; and much depends on the fissures the well may happen to pierce, as the main flow in many rocks takes place along their fissures. It is disadvantageous to sink a well where the superincumbent impervious stratum is very thick, not merely because of the depth that has to be sunk before reaching water, but also on account of the slow rate of the underground flow at a long distance from the outcrop, and owing to the compression of the porous stratum by the mass above it. For instance, the deep well on Southamptom Common, sunk through 465 feet of impervious beds, has only yielded a small supply of water, though carried 852 feet into the chalk. A well may also prove a failure owing to a fault or an impervious barrier interrupting the underground flow, if it is sunk on the side of the fault or barrier away from which the dip of the stratum inclines. Thus a well sunk at A (Fig. 2) will receive the water flowing along the permeable stratum; whilst an adjacent deeper well at B will yield no water, on account of the interruption of the flow. As there is a limit to the underground waters, only a limited number of wells can be advantageously sunk within a certain area; and a multiplication of wells, such as has occurred in the London basin, permanently lowers the water-level of the underground reservoir, and involves an increased lift in pumping to maintain the supply. Wells drawing their supplies from the same sources as springs reduce the yield of the springs issuing from the strata which they pierce; and when these springs feed rivers the volume of these rivers is thereby somewhat diminished. Wells, however, sunk into strata draining to the sea-coast merely intercept water which otherwise would be absolutely lost. A useful well for small supplies is a tube well, which consists of a series of strong wrought-iron pipes, between 1 and 2 inches in diameter, the bottom length being terminated in a point, and perforated with little holes for a short distance up.[1] The point is driven into the ground by a falling weight, as in pile-driving; and, as the tube descends, fresh lengths of pipe are screwed on the top. When the perforated pipe reaches a water-bearing stratum, the water enters through the holes and is raised by a pump (compare descriptions and diagrams of tube wells under PETROLEUM, vol. xviii. pp. 729–31).

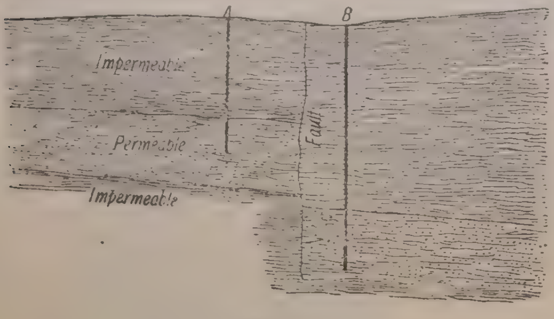

FIG. 2.

EXTENSION OF SUPPLY.

A supply obtained from wells may be increased by reaching the water flowing through undrained fissures or lying in untouched cavities, either by sinking fresh wells, or by driving headings from the bottom of existing wells in various directions, both of which courses were adopted for extending the Brighton water-supply. Continued pumping sometimes improves the supply when the stratum is well saturated and the drain is not sufficient to lower the water-level permanently. This result is due to the steepening of the gradient of flow towards the well by the depression of the water-level in the well, which increases the velocity of flow, whereby the channels of access are cleared out and enlarged, so that the water flows more readily and quickly into the well than at the commencement.

The supply from springs and streams can only be increased by storing up the excess of supply in the wet season, to make up for the deficiency in the dry season. This can be accomplished by means of storage reservoirs, which sometimes are found suitably provided by nature in the form of lakes, or may be constructed in mountain valleys by means of dams.

RESERVOIRS.

Lakes as Reservoirs.—A lake is a natural reservoir of water, caused by the influx of a stream into a depression of an impermeable stratum, which is barred to a certain height by a ridge across its outlet, over which the water has to rise before it can flow away (see LAKE). The water of lakes is generally of exceptional purity, owing to its being usually supplied by the drainage from the impervious uncultivated ground of uninhabited mountainous districts, and its general freedom from pollution, and on account of the lake serving as a deep subsiding reservoir for any matters in suspension contained in the inflowing streams, of which the Lake of Geneva in relation to the turpid upper Rhone is a notable instance. Glasgow is supplied with excellent water from Loch Katrine (see AQUEDUCT, vol. ii. pp. 196–8); it was at one time proposed to supply Edinburgh from St. Mary's Loch, and London from Bala Lake; and works for the conveyance of water from Thirlmere, in Cumberland, to Manchester are in progress. To increase the storage capacity of a lake intended to serve as a reservoir, and avoid injury to vested interests, the ordinary water-level of the lake has to be raised by heightening the barrier at its outlet. By this means the lake is not unduly lowered by the drain upon it during the dry season, and compensation water is provided to supply the water-rights along the stream below. The extent to which the water-level of the lake has to be raised depends upon the area of the lake, the influx into it, and the supply drawn off; thus Loch Katrine, with an area of 3000 acres, needed only a rise of 4 feet in order that, with a maximum lowering of 7 feet, it might provide a storage of 5687 million gallons for a supply of fifty million gallons per day; whereas the water-level of Thirlmere, with an existing area of only 350 acres, requires raising 50 feet to furnish a storage of 8100 million gallons for a similar daily supply. The amount of water that can be collected depends on the catchment area, and the rainfall of the driest years, less the loss from evaporation; and the supply which can be relied upon from any definite gathering ground is given by the formula $Q = 62.15 A (\frac{4}{5} R - E)$, where Q is the daily supply in gallons, A is the catchment area in acres, R is the average annual rainfall and E the loss from evaporation, both in inches.[2] The storage capacity must be regulated by the number of consecutive days, in time of drought, that the supply might have to be drawn from the reservoir without its receiving any accession of water. This period has been variously estimated at from 70 to 300 days according to the locality; for, owing to the smaller fluctuations in the rainfall and in the periods of drought in very rainy districts, and the less amount of evaporation, a much smaller storage suffices for very wet districts than for very dry ones.

Storage Reservoirs.—Where no natural lake is available for a reservoir, an artificial lake may be formed by constructing a dam across a narrow gorge of a mountainous valley, thereby impounding, in the winter, the stream draining the valley, and storing up a supply for the following summer. To prevent an escape of the water thus impounded, the reservoir must be formed on an impervious stratum, and all cracks and fissures closed, or the bed and banks must be rendered watertight by a surface layer of impervious material. Occasionally the configuration of the ground and the amount of storage required render it necessary to form a series of impounding reservoirs at different levels along a valley, thereby increasing the number, but keeping down the height of the dams. For instance, in supplying Manchester from the Longdendale valley, six large reservoirs, having a total area of 497 acres, and a capacity of 4160 million gallons, were formed in steps by dams from 70 to 100 feet high (see AQUEDUCT, vol. ii. pp. 195–6).

RESERVOIR DAMS.

The capacity of a reservoir depends upon the form and levels of the valley in which it is situated, and the height of the dam retaining it. As, however, the extent of the water surface is considerably increased by raising the water-level, an additional height of dam adds largely to the capacity of a reservoir. Thus Thirlmere, with an existing maximum depth of 108 feet, will have its area increased from 350 to 800 acres by raising the barrier at its outlet 50 feet. Accordingly, dams of considerable height are sometimes erected; as, for instance, the Entwistle embankment of the Bolton waterworks, retaining a reservoir 120 feet deep, the Villar Dam, for the supply of Madrid, founded 158½ feet below the water-level of its reservoir (Fig. 7), and the Furens dam, near St. Étienne, with a height of 164 feet at the water level (Fig. 5); whilst the Gileppe dam, near Verviers, was made 147¾ feet high (Fig. 6) in preference to four dams of 95 feet.

---

[1] [This sort of well is known in the United States as a "drive" or "driven well."—AM. ED.]

[2] *Theory and Practice of Hydro-Mechanics*, Inst. C. E., p. 44.

A reservoir dam is constructed either with earthwork in an embankment sloped on each side, and with a watertight puddle or concrete trench along the centre, or of masonry. Earthwork embankments have, till within the last three or four years, been exclusively adopted in Great Britain; whilst masonry dams have been long ago constructed in Spain, and more recently introduced into France.

Earthen Embankments.—In moist climates, and for moderate heights, embankments of earth are adopted with advantage for reservoir dams, more especially when ample materials can be readily obtained, either by excavations in the reservoir, thus enlarging its capacity, or elsewhere near at hand, and where a rock foundation is not easily attainable. All loose material must be removed from the site of the dam; and the puddle trench in the centre must be carried down to a solid impervious bed (Fig. 3). The embankment must be brought up in thin layers carefully punned or rolled, the most retentive materials being placed near the middle, and the looser materials towards the outside. The inner slope, facing the reservoir, is usually made 3 to 1, and pitched on the surface to protect it from the wash of the waves. The outer slope is formed to the angle of stability of the material employed, generally 2 to 1; and occasionally berms are introduced, diminishing the liability to slips (Fig. 4). The best puddled clay is used for the central trench; but the remainder of the embankment should not be composed exclusively of clay, as stiff clay under the influence of the weather, especially on the exposed outer slope, tends to slip. An earthen dam possesses ample stability if it is perfectly solid; but it may fail from the infiltration of water through it, owing to faulty construction, or from settlement, leading to its overtopping by the water in the reservoir.

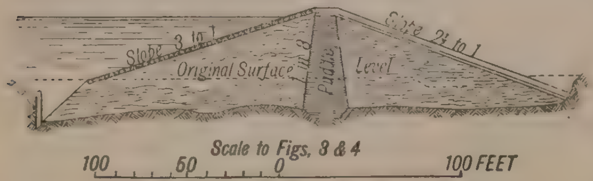

FIG. 3.—Nethertrees Reservoir Embankment, Paisley.

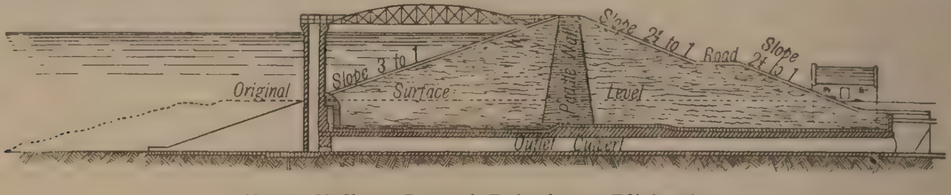

FIG. 4.—Gladhouse Reservoir Embankment, Edinburgh.

Masonry Dams.—In hot dry countries, an earthen embankment is liable to crack and become somewhat disintegrated; and high embankments, owing to their flat side slopes, require a very large amount of material. Accordingly, in Spain, masonry dams have been adopted; and they are preferable to earthen dams when the height exceeds about 80 feet, and where a rock foundation can be secured. The Spanish masonry dam of Puentes (Lorca), 164 feet high, was indeed built upon piles; but it was eventually undermined, and settled; and the outburst of the water from the reservoir on its failure in 1802 caused the loss of 608 lives. Besides a solid rock foundation, the conditions of stability of a masonry dam are that the maximum pressure shall not exceed the limit that the masonry can sustain without injury, and that the lines of resultant pressure, with the reservoir empty and full, shall not anywhere pass outside the middle third of the section of the dam, so as to prevent the possibility of tension at the faces. With the reservoir empty, the pressures on the dam are merely those due to its weight; and the line of resultant pressures is the locus of the points of intersection of the verticals from the centres of gravities of the several portions of the dam above a series of horizontal lines, with the base lines of those portions (Figs. 5 and 8). With the reservoir full, the water exerts a horizontal thrust against the inner face of the dam, equal to the weight of a column of water having the depth of the water resting against the dam, and acting at the centre of pressure, which is at two-thirds of the depth down from the water-level. The line of resultant pressures, in this case, is the locus of the points obtained by the intersection of the resultant lines of the pressures of the masonry and the water on the portions of dam, at different distances from the top, with the horizontal base lines of these portions (Figs. 5 and 8). The direction and amount of the resultant are readily obtained graphically by the parallelogram of forces, the point of application being at the intersection of the vertical from the centre of gravity with the horizontal line one-third up from the base; for, by drawing the horizontal and vertical lines proportionate in length to the water-pressure and weight of the dam respectively, the diagonal represents the resultant of these forces both in magnitude and direction. When the inner face of the dam is battered, the weight of water resting on this face must be added to the weight of the dam when the reservoir is full. The resultant pressures necessarily increase with the depth; and the maximum pressure is at or near the base of the inner face when the reservoir is empty, and of the outer face when the reservoir is full. The top has only to be made wide enough to resist the shock of the waves and floating ice in the reservoir; but the base, having to bear the weight of the dam together with the water-pressure, requires widening out adequately for the safe limit of pressure on the masonry not to be exceeded; and as the water-pressure with the full reservoir deflects the resultant towards the outer face, this face is given a considerable batter (Fig. 5). All dams have to be raised high enough not to be overtopped by the highest waves in a storm, depending on the size and exposure of the reservoir.

Sections of three of the largest masonry dams erected within the last twenty-five years, namely, Furens, Gileppe, and Villar (Figs. 5, 6, and 7), as well as the Vyrnwy rubble concrete dam, now in course of construction (Fig. 8), drawn to the same scale, illustrate the forms adopted for these dams. The Furens and Villar dams follow closely the theoretical requirements; whilst the Gileppe and Vyrnwy dams, with their excess of thickness, impose an unnecessary weight on the base, and absorb extra material, without any adequate compensating advantage. Provision, however, was made in the section of the Gileppe dam to admit of its being raised at some future time, and for a roadway along the top, which in some measure accounts for its excess of width; and the Gileppe and Vyrnwy dams are the first examples of such structures in Belgium and Great Britain.

The Furens dam (Fig. 5), constructed in 1859–66, across the Gouffre d'Enfer, for forming a reservoir with a capacity of 56½ million cubic feet, has a maximum height of 183 feet, and a length along the top of 337 feet; and the maximum pressure on the masonry is 6.1 tons per square foot on the inner face, a few feet above the base, with the reservior empty; whereas, with the reservoir full, the maximum pressure on the outer face is under 6 tons. No allowance was made for the arched form of the dam, in plan, towards the reservoir, which reduces the pressure, due to the head of water, at the lower part where the valley is very contracted, and would have admitted of the omission of the projecting outer portion for the bottom 60 feet. A very low limit of pressure, in addition to the excess of strength just referred to, was adopted, owing to the unprecedented height and type of the Furens dam. By raising, however, the limit to 6.6 tons per square foot, it was possible to reduce the section of the Ban dam, 138 feet in height at the water-line, making it 110½ feet wide at the base, as compared with 116½ feet for the Furens dam at the same depth; whilst with the same limit applied to a dam of the full height of the Furens dam, the reduction in width at the base would be from 161 to 154 feet.[1] Any further raising of the limit of pressure, which might be safely effected would be of little advantage for dams down to a depth of about 100 feet, as the reduction in width is restricted by the condition of the middle third; but beyond that depth the width is regulated by the pressure.

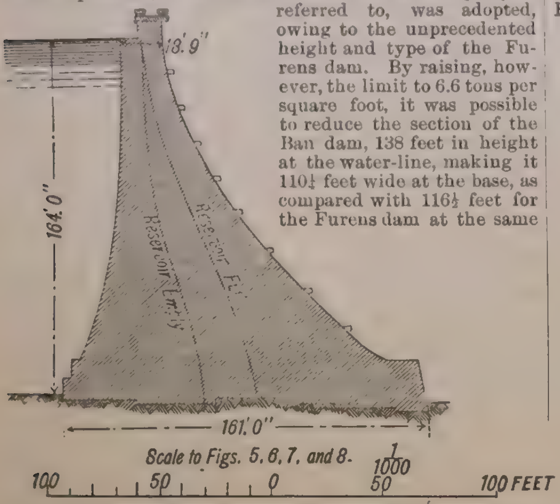

Fig. 5.—Furens Reservoir Dam, near St. Étienne.

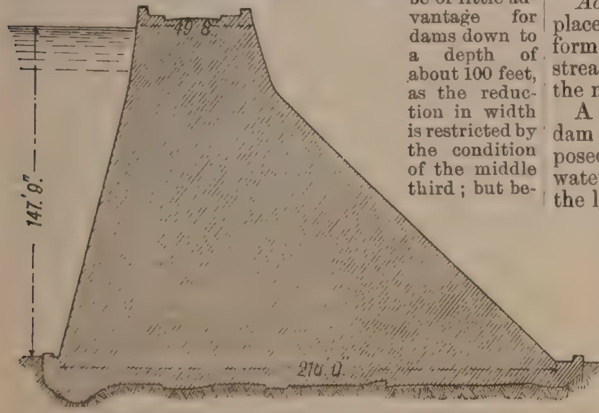

Fig. 6.—Gileppe Reservoir Dam, near Verviers.

The Gileppe dam (Fig. 6), built in 1869–75, having a maximum height of 154 feet, and a length along the top of 771 feet, retains a reservoir with a capacity of 423¾ million cubic feet. The average pressure on the base is 8.2 tons per square foot; so that, even allowing for the specific gravity of the masonry being about one-seventh greater at Gileppe than at Furens, the maximum pressure on the Gileppe dam is considerably greater than on the Furens dam, in spite of its greater base and the smaller head of water (compare Figs. 5 and 6), owing to the excess of material employed in its construction.

The Villar dam (Fig. 7), built across the river Lozoya in 1870–78, convex towards the reservoir as at Furens and Gileppe, has a maximum height of 168¾ feet, and a length along the top of 546 feet; and it forms a reservoir having a capacity of 70¾ million cubic feet. It differs very little in height and type from the Furens dam; but the form given to the batter of the outer face is calculated to render the pressures more uniform towards the base.

The Vyrnwy dam (Fig. 8), now (1888) in course of construction, across the Vyrnwy in Montgomeryshire, for forming a reservoir, 1100 acres in area, to supply 40 million gallons per day to Liverpool, is to sustain a maximum head of water of only 70½ feet; but, as it has to be carried down about 60 feet below the surface, in the centre of the valley, to reach solid rock, its maximum height is about 140 feet, and its length along the top is 1350 feet. The maximum pressure on the inner face with the reservoir empty has been estimated at 8.7 tons per square foot, and with the reservoir full at 6.7 tons on the outer face. These pressures are considerably in excess of the maxima pressures on the Furens dam, though the head of water to be supported is much less, and the width at the base is greater in proportion to the depth. The pressures at the base in the Vyrnwy and Gileppe dams show that a superabundant mass of material in a masonry dam, whilst involving a larger outlay, imposes a greater pressure upon the masonry, whereas the stability is ample in the Furens type; and the oozing of water through the dam should be provided against by the quality of the materials and workmanship, rather than by an extra thickness of masonry.

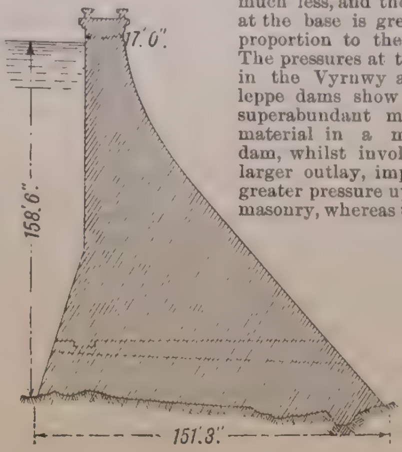

Fig. 7.—Villar Reservoir Dam, near Madrid.

Accessory Works.—Sometimes a small dam is placed across the upper end of a reservoir, so as to form a small settling reservoir, in which the inflowing stream can deposit any sediment before passing into the main reservoir.

A waste weir is provided at a suitable place in the dam with its sill slightly lower than the highest proposed water-level in the reservoir, so that the surplus water, when this level is reached, may flow over into the lye-wash. The length of the weir should be made sufficient for the discharge over it to pass off the inflow during a flood, so as to ensure the dam against being overtopped by a rise of water in the reservoir, which would be fatal to an earthen dam. To provide for a large discharge without a great length of weir, the sill of the weir may be placed somewhat lower, and planks placed temporarily across it to retain the water at its highest level on the approach of the summer.

The water is drawn off from the reservoir, as required for supply, through an outlet culvert passing from a low level in the reservoir into a conduit in the valley below. This culvert was formerly frequently placed through the lowest part of the dam, being readily formed during the construction of the dam, and giving command of all the water in the reservoir. Accidents, however, have often been traced to the unequal settlement of the earthen embankment near the culvert, or to infiltration of water into the embankment, either by escaping from the culvert fractured by settlement, or by finding a passage along the outside line of the culvert or pipes. Thus the bursting of the Dale Dike embankment, 95 feet high, near Sheffield, in 1864, on the occasion of the first filling of the reservoir behind it, having a capacity of 114 million cubic feet, which entailed the

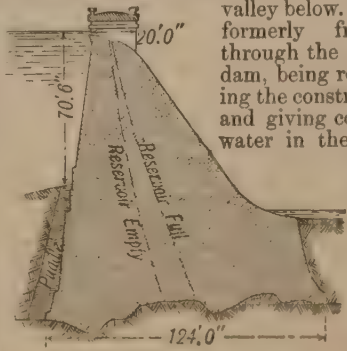

Fig. 8.—Vyrnwy Reservoir Dam.

---

[1] *Annales des Ponts et Chaussées*, 4th ser., vol. xii. pl. 127.

loss of 238 lives, was attributed to the unequal settlement and consequent cracking of the puddle wall over the trench in the rock in which the outlet pipes were laid, aggravated in this instance by the defectiveness of the material in the main bank, the rough manner in which the bank was raised, and the rapid filling of the reservoir. The percolation of the water under pressure along the line of outlet pipes was the cause of the gradual failure of the embankment, 41 feet high, across the Lynde Brook, Worcester, Mass., which burst in 1876 and set free a reservoir with a capacity of 110 million cubic feet.

No possible considerations can justify the burying of outlet pipes at the base of a high embankment, with the valves regulating the discharge at the outer extremity, whereby the water-pressure always acts along the whole length of the pipes, and their inspection is impracticable. In some cases a valve-tower is erected in the centre of the embankment, by which means the water can be shut off from a portion of the pipes. If, however, the outlet pipes are carried under the embankment, they should be laid in the solid ground, and should be commanded along their entire length by a valve-tower placed at the inner toe of the embankment (Fig. 4). Nevertheless, it is far safer to carry the outlet pipes in a tunnel constructed through the side of the valley, beyond one end of the embankment. In the case of masonry dams, the outlet is generally constructed in the solid rock distinct from the dam; but at Villar the outlet culvert has been carried through the centre of the dam (Fig. 7).

CONVEYANCE OF SUPPLY.

A reservoir in a mountain valley is at a sufficient elevation for the water to flow by gravitation to the locality to be supplied; and it is only necessary to form a conduit by canals, tunnels, aqueducts, and pipes, of adequate size in relation to the gradient, to convey the daily supply required (see HYDROMECHANICS). In olden times hills were contoured, and valleys were crossed by colossal aqueducts, at great expense, to obtain a regular inclination, which was reduced by the circuitous route that had to be taken (see AQUEDUCT). Now, however, hills are pierced by tunnels; and, by the employment of cast-iron, deep wide valleys can be crossed by inverted siphons following the depressions of the land,—so that a much straighter course is attainable, affording better gradients, and therefore enabling smaller conduits to be adopted, which is of great importance when long distances have to be traversed. Thus the waters of Thirlmere, after being discharged through a tunnel formed under the Kirkstone Pass at the south end of the lake, instead of at the natural outlet to the north, will be conveyed to Manchester by a conduit 96 miles long, with a total fall of 178 feet. Portions of the route are in tunnels, 7 feet square, the longest tunnel being a little over 3 miles long; and there are several inverted siphons, to be formed of five cast-iron pipes, each 3⅛ feet in diameter, the longest siphon being 3⅛ miles, and that under the river Lune having to bear a water pressure of 416 feet. The water from the Vyrnwy reservoir will be conveyed to Liverpool in a conduit 67 miles long, of which 4 miles will be in tunnel, and will furnish a supply of 40 million gallons per day. A large supply of water from the river Verdon for the district round Aix, serving for irrigation and manufactures, as well as for domestic purposes, is conveyed across the valley of St. Paul in an inverted siphon formed of two wrought-iron tubes, each 5¾ feet in diameter.

The water obtained from rivers in low districts, and from wells, has to be raised by pumping to the height necessary to obtain a proper pressure for supply; and the pumps have to be in duplicate, to prevent a failure in the supply in the event of a break-down. Thus the water-supply of London has to be raised by pumping to fill the service reservoirs.

PURIFICATION.

The water obtained for supply is frequently not sufficiently pure to be at once distributed for domestic purposes. The impurities to which water is liable are of three kinds, namely, particles of matter in suspension, inorganic substances in solution, and organic matters in solution or of extreme minuteness. Suspended matters are readily removed by subsidence if the particles are heavy, and by filtration if the particles are flocculent or light. Some inorganic compounds are readily removed, whilst others cannot be dealt with in a practical manner. The removal of organic impurities is of the most importance, and the most difficult, which has led to the great care exercised in selecting unpolluted supply.

Settling-Reservoirs.—Allusion has already been made to subsiding reservoirs formed at the head of large storage reservoirs; the object of these, however, is rather to prevent the accumulation of silt and sand in the principal reservoir than for the purpose of purification, but the principle is the same. Supplies from large reservoirs are generally free from matters in suspension, except sometimes during heavy floods, owing to the subsidence in the reservoir itself; but river supplies have often to be led into settling-reservoirs, where the water, whilst at rest, can deposit its heavier particles before passing on to the filter-beds for the removal of the lighter portions.

Filter-Beds.—Over the bottom of brick tanks layers of clean material are spread, decreasing in coarseness from small rubble to sharp sand, with a total average thickness of about 4 feet. The actual filtration is effected by the upper layer of sand; and the lower layers allow the passage of the water unaccompanied by the sand. The efficiency of the filtration depends upon the slowness of the passage of the water, which should not exceed a flow of from 2½ to 3 gallons per square foot of area per hour. The filter must periodically be cleaned by scraping off the top surface of the sand, which becomes choked with the matter removed from the water; and after a time a fresh layer of sand has to be provided. Filtration, though in itself a purely mechanical operation, has been found to reduce the organic impurities in the water, which must be due either to their oxidation from exposure in thin layers to the air in the process of filtering or to the actual removal of very minute organisms floating in the water, or probably to both causes combined.

Filters of spongy iron mixed with gravel were set up at the Antwerp waterworks in 1881, and arrested a quantity of matter which had passed through an upper layer of sand, and proved very efficient agents for purification. Their large cost, however, their becoming rapidly clogged and caked on the top, necessitating the removal of the upper layer of sand to break up the hard top iron crust, and the rather frequent renewal of the iron required, as compared with sand, were a bar to the extension of the system, which had become inadequate for its work. Eventually, it was found that the purification could be effected more economically and rapidly, and quite as effectually, by scattering cast-iron borings in the water as it flowed through horizontal revolving cylinders, furnished with projecting plates fastened at intervals round the inside, which, in revolving, scooped up the iron at the bottom, which had fallen through the water, and discharged it on reaching the top. The iron is first converted into ferrous oxide, FeO, which dissolves, at least partly, as bicarbonate, and then by further oxidation into ferric oxide Fe_2O_3, which readily precipitates, and is easily removed by filtration through sand, a small portion only of the oxide remaining in solution. Iron appears to purify water from organic matter, partly by its fatal influence on the growth and even life of micro-organisms, and partly by dragging down the floating organisms in the process of precipitation.

Softening Water.—Many waters drawn from springs, wells, and rivers fed by springs contain inorganic salts in solution, and, though innocuous and pleasant for drinking, are not good for general domestic and manufacturing purposes, owing to their curdling soap and encrusting kettles, boilers, and pipes. This quality, known as *hardness*, is mainly due to salts of lime, which are found in large quantities in waters drawn from the chalk. Most of the lime in solution is in the form of bicarbonate, $CaO.2CO_2$, having been produced from the very slightly soluble carbonate of lime, $CaO.CO_2$, of which chalk and other limestones are mainly composed, by combination with free carbonic acid, CO_2. It is only therefore necessary to remove half of the carbonic acid from the bicarbonate to reconvert it into the insoluble carbonate. This can be done either by boiling, which drives off the excess of carbonic acid, depositing the carbonate of lime which forms the troublesome incrustation in pipes and boilers where chalk water is used, or by adding caustic lime, CaO, to the water, which, combining with the excess of carbonic acid, reduces the bicarbonate, forming carbonate of lime, which is precipitated. This reaction is indicated by the formula $CaO + CaO.2CO_2 = 2CaO.CO_2$, and is the basis of Dr. Clark's process for softening water. To indicate the degree of hardness of various waters, Dr. Clark's scale of 1 degree of hardness for each grain of chalk in 1 gallon of water is employed. Some waters have 22°, or even more degrees of hardness; and all waters are termed hard which contain more than 5°; but by the softening process waters of 22° of hardness can be reduced to about 5°. The remaining or permanent hardness consists of sulphate of lime and other soluble salts. The conversion of the bicarbonate in the process of softening is rapid; but the difficulty of dealing with the fine precipitate, which requires time to settle, has hindered the general adoption of the process, though it has been applied successfully at various works deriving their supply from chalk wells. The precipitation of the carbonate of lime in the softening process has been observed to remove to a great extent the micro-organisms in the water, confirming the view expressed above, that precipitation sweeps down with it the minute germs, as in this case the chemical action could not influence them. The waters obtained from mountainous districts are very soft, and therefore very valuable for manufacturing districts; but they have more action upon lead, and are more liable to absorb organic impurities than water highly charged with inorganic salts.

Storage.

Quantity of Daily Supply.—The water-supply required is estimated in gallons per head of population, with additions in manufacturing districts for trade purposes. The consumption varies greatly in different towns, ranging from about 12 to 50 gallons per head per day; and it depends more upon the fittings and other sources of waste than upon the habits of the population, though the consumption per head is greater in the wealthier quarters. An ample supply, for domestic and general requirements, is from 20 to 25 gallons per head daily. The actual rate of consumption varies with the time of day, and also with the period of the year, being greatest between 7 and 10 A.M., and in June, July, and August, and least from 9 P.M. to 5 A.M., and in January, February, and March.

Where the quality of the supply drawn from different sources varies, as in London (the water from the deep wells in the chalk being far superior to that derived from the Lea), and where filtration has to be largely adopted, it is unfortunate that the best supply cannot be devoted to drinking and cooking, and the inferior in quality and unfiltered waters used for cleaning, for gardens, stables, water-closets, flushing sewers, watering the streets, and extinguishing fires. Besides, however, the cost of a duplicate system of mains and pipes, with the addition, in London, of difficulties between independent companies, the carelessness of persons in drawing from the two supplies has been considered a bar to this separation. It is possible, however, that, when the population becomes still more dense, and pure water more difficult to obtain, these objections may be overruled, and the purest supply devoted to special uses.

Service-Reservoir.—To provide a sufficient reserve for sudden demands, such as for a fire, and to ensure an adequate supply to every house, a service-reservoir has to be constructed, into which the water from the source of supply is led. The reservoir consists generally of a brick or concrete tank, rendered water-tight inside with cement, sunk in the ground, and roofed over with brick arches resting on the side walls and intermediate pillars, over which a covering of earth is spread. By this means light and heat are excluded, which, together with a depth of at least 15 feet of water, prevents the growth of minute aquatic plants, of which the germs are found in some well waters, particularly from the New Red Sandstone, and maintains the water at a tolerably even temperature. The reservoir should have a capacity of not less than twenty-four hours' supply, and should be at a sufficient elevation to command the whole of the district it serves, and if possible afford a good pressure on the fire-hydrants. Where a town stands at very different levels, separate reservoirs at different elevations for supplying the high-level and low-level districts are advisable, to equalize the pressure.

Distribution.

The water is led from the service-reservoir through cast-iron mains to the branch mains, from which the service pipes convey it to the several houses. Lead is generally preferred for house connections, owing to the facility with which it can be adapted to structural requirements. The only objection to it is that it is attacked by some very soft waters, oxide of lead being formed, which is partially soluble and very injurious to health. With free carbonic acid, however, the pipe becomes coated with carbonate of lead, which is insoluble in water and protects the pipe from further action. Peat also in water protects the lead pipes, by depositing a surface film. In the case of hard waters, the lead soon becomes coated with sulphate of lime. Accordingly, it is only under exceptional conditions that the employment of lead for pipes is deleterious; but it should be prohibited for the lining of cisterns where the water may be stored for long periods.

Domestic filters are very valuable for local well and spring supplies, and afford an additional safeguard against accidental impurities in public supplies (see FILTER).

Intermittent and Constant Supply.—Formerly the common form of supply was on the intermittent system. On this plan, each house is provided with a cistern, into which water from the main is admitted for a short period, once or twice a day, by means of a valve on each service main, which is opened and closed by the turncock for each separate district. When the cistern is filled, the inlet pipe is closed by the rising of the floating ball shutting the ball tap. The supply is, accordingly, limited to the contents of the cistern, except during the short period the water is turned on; and the cistern is proportioned to the accommodation of the house. The water in these open cisterns is liable to contamination from impurities of various kinds settling in them and not being cleaned out; and it is often exposed to heat, a smoky atmosphere and dust, and sometimes to sewage gas. Moreover, in the event of a fire, the turncock has to be summoned before a supply of water can be obtained. Accordingly, the adoption of the constant system has been urged, and in many places carried out. The advantages of drawing a fresh supply always direct from the main, and of having an ample supply constantly at hand to meet any emergency are unquestionable; but the constant supply of water necessitates the strengthening and very careful inspection of the pipes, joints, and fittings to prevent fracture and avoid leakage under a continual and increased pressure, and is liable to lead to a careless waste of water if unchecked by a meter. Before substituting a constant for an intermittent supply, it is essential to overhaul thoroughly the pipes and joints, and to substitute screwdown taps, which close gradually, for the leaky suddenly-closing plug-taps, which throw a sudden pressure on the pipes. Waste in water-closets can be stopped by the insertion of a waste preventer, which only allows a definite quantity of water to pass each time the plug is raised (see Sewerage). The detection of accidental waste from leakages has been much facilitated by the introduction of a waste-water meter, which records graphically, on a revolving cylinder, the amount of water which is passing the place where the meter is fixed. By fixing the meter on one of the district mains at night, when most of the recorded flow is running to waste, and shutting off successively the service pipes through which water is heard to be flowing, the change in the diagram of flow at each closing of a service pipe localizes the position and extent of each source of waste, showing at what places leaks must be occurring, and which are the worst, needing attention first. This method of inspection was first adopted at Liverpool in 1873; and besides effecting a considerable economy, it enabled the constant service to be restored, which the previous waste had rendered impracticable.

Water Meters.—There are two classes of water-meters,—the positive and the inferential. The positive meter, such as Kennedy's and Frost's piston meters, measures the actual quantity of water passed through it, as recorded by the strokes of a piston working in the cylinder, which is successively filled from the top and bottom, and affords a measure of the water introduced; whilst the inferential meter, such as that of Siemens, measures only the revolutions of a turbine actuated by the flow of the passing water, of which the quantity is deduced from the velocity. The positive meter is more accurate, and measures very small flows; whereas the turbine meter may sometimes not be turned by very small flows which are gradually increased. Measurement by meter would seem naturally to follow the adoption of the constant service for domestic supply, as well as for manufactories. Its general adoption has, however, been hindered by the fear that a charge by quantity, instead of by rental, might press unduly upon the poorer classes, and induce them to stint themselves of a proper supply, and also the difficulty of obtaining a very cheap and at the same time a perfectly trustworthy meter of adequate durability. To avoid the possibility of checking a sufficient use of water in the poorer tenements, it has been proposed to allow a definite supply at the ordinary rate, and only to charge by meter for any excess over this amount. (L. F. V.-H.)

WATERTON, Charles (1782–1865), naturalist and traveller, descended from a very ancient English family, was born at Walton Hall, near Pontefract, Yorkshire, in 1782. After being educated at the Roman Catholic College of Stonyhurst, and travelling a short time on the Continent, he went to Demerara to manage some estates belonging to his family. He continued in this occupation for about eight years, when he began those wanderings upon the results of which his fame as a naturalist principally rests. In his first journey, which began in 1812, and the principal object of which was to collect the poison known as curari, he travelled through British Guiana by the Demerara and Essequibo rivers to the frontiers of Brazilian Guiana, making many natural history collections and observations by the way. After spending some time in England he returned to South America in 1816, going by Pernambuco and Cayenne to British Guiana, where again he devoted his time to the most varied observations in natural history. For the third time, in 1820, he sailed from England for Demerara, and again he spent his time in similar pursuits. Another sojourn in England of about three years was followed by a visit to the United States in 1824; and, having touched at several of the West India islands, he again went on to Demerara, returning to England at the end of the year. In 1828 he published the results of his four journeys, under the title of *Wanderings in South America*—consisting largely of a collection of observations on the appearance, character and habits of many of the animals to be found in British Guiana. Waterton was a keen and accurate observer, and his descriptions are of a graphic and humorous character, rarely to be found in works on natural history. He married in 1829, and from that time lived mostly at Walton Hall, devoting himself to the improvement of his estate, to country pursuits, and to natural history observations. Waterton also published three series of essays on various subjects connected with natural history. He died May 27, 1865, from the result of an accident.[1]

WATERTOWN, a city of the United States, the county seat of Jefferson county, New York, is situated upon both sides of Black River, 7 miles above its mouth, and is 140 miles northwest of Albany. It is laid out rather irregularly, with 60 miles of streets, is supplied with water by pumping, water-power being used, and is well-sewered. The population in 1880 was 10,697, including 2444 of foreign birth. The river at this point is 60 yards wide. It falls 112 feet in two miles, and flows through the city in a succession of rapids, furnishing a magnificent water-power to the numerous paper, woollen, and cotton mills and machine shops which line its banks.

The first settlement was made in 1800, and the town had a rapid growth from the start. The city was chartered in 1869.

WATERTOWN, a city in Jefferson and Dodge counties, Wisconsin, United States, is situated upon both sides of Rock river, in a rich farming region. Its population in 1880 was 7883, 3072 of them of foreign birth. The river furnishes a valuable water-power for extensive manufactures. Watertown contains the Northwestern University, a Lutheran institution, and a Roman Catholic seminary. About two-thirds of the present population are Germans or their direct descendants.

WATERWORKS. See Water-Supply.

WATFORD, an ancient market town of Herts, is situated on a ridge of gravel overlooking the river Colne, on the Grand Junction Canal and on the London and Northwestern Railway, branches of which here diverge to St. Albans and to Rickmansworth, 8 miles southwest of St. Albans and 17¾ northwest of London by rail, the distance by road from Charing Cross being 15 miles. It consists chiefly of one spacious street, about 1½ mile in length, running northwestwards from the river. A bridge connects it with Bushey on the south side of the river, a suburb chiefly of villas. The church dedicated to St. Mary, with embattled tower and spire 100 feet high, was restored in 1871 at a cost of £11,000 [$53,460]. The other principal public buildings are the masonic hall (1873), the public library and school of art, a building of brick in the Gothic style, erected in 1873–74 at the cost of £3400 [$16,524], the county court and sessions-house, the agricultural hall, and the literary institute. Among the benevolent institutions are the London Orphan Asylum, founded in 1813, rebuilt in 1870 in the Elizabethan style, and having accommodation for 600 children; the almshouses of the Salters Company, London, and the almshouses erected in 1876 by the countess of Essex for superannuated servants. There is a cemetery of 14 acres laid out in 1858. For the water-supply of the town a reservoir capable of containing one million gallons has lately been constructed. The town possesses corn-mills, breweries, malt-kilns, and an iron foundry. The population of the urban sanitary district (area 530 acres) in 1871 was 7461, and in 1881 it was 10,073. In 1882 the area of the urban sanitary district was extended to 871 acres; the population of that area in 1881 was 12,162.

---

[1] [Waterton was one of the first to practice taxidermy systematically.—Am. Ed.]

Watford is not mentioned in Domesday, being then included in the manor of Cashio, belonging to the abbey of St. Albans. The town received the grant of a market from Henry I. When the abbey of St. Albans was dissolved in 1549, Watford fell to the crown. In 1609 it came into the possession of Thomas Marbury, and it has belonged to the earls of Essex since 1767.

WATSON, RICHARD (1737–1816), bishop of Llandaff, was born in August, 1737, at Heversham, in Westmoreland, and was the son of the master of the grammar school of that place. He was entirely educated by his father, who sent him in 1754 to Trinity College, Cambridge, with "a considerable stock of classical learning,[1] a spirit of persevering industry, and an obstinate provincial accent." He was elected a fellow of Trinity in 1760, and about the same time had the offer of the post of chaplain to the factory at Bencoolen. "You are too good," said the master of Trinity, "to die of drinking punch in the torrid zone," and Watson, instead of becoming, as he had flattered himself, a great Orientalist, remained at home to be elected professor of chemistry, a science of which he did not at the time possess the simplest rudiments. "I buried myself," he says, "in my laboratory, and in fourteen months read a course of chemical lectures to a very full audience." Not the least of his services was to procure an endowment for the chair, which served as a precedent in similar instances.

In 1771 he became a candidate for the regius professorship of divinity, and at the age of thirty-four gained what he calls "the first place for honor in the university," "and," he adds, "exclusive of the mastership of Trinity College, I have made it the first for profit. I found it not worth £330 [$1603.80] a year; it is now (1814) worth £1000 [$4860] at the least." He did not entirely renounce the study of chemistry: in 1768 he had published *Institutiones Metallurgicæ*, intended to give a scientific form to chemistry by digesting facts established by experiment into a connected series of propositions. In 1781 he followed this up with a volume of *Chemical Essays*, which Davy told De Quincey remained as late as 1813, after all recent discoveries, unsurpassed as a manual of introductory discipline. But on the day on which he composed his preface he burned all his chemical manuscripts, and never returned to the subject. His course as professor of divinity was no less decisive. "I reduced the study of divinity into as narrow a compass as I could, for I determined to study nothing but my Bible." He produced several anonymous pamphlets on the liberal side in the subscription controversy and other topics of the day, and some sermons, one of which was thought likely to have involved him in a prosecution, but, which Dunning said, contained "just such treason as ought to be preached once a month at St. James." It is said to have prevented his obtaining the provostship of Trinity College, Dublin. In 1776 he answered Gibbon's chapters on Christianity, and had the honor of being one of the only two opponents whom Gibbon treated with respect. In 1781 he was prostrated with a malignant fever, from the effects of which he never wholly recovered, and which served as an excuse for that neglect of many duties which remains the chief stain upon his character. He had always opposed the American War, and when the accession of Lord Shelburne to power in 1782 afforded the then unfrequent opportunity of advancing a Liberal in politics and religion to a bishopric, Watson was made bishop of Llandaff, being permitted to retain his other preferments on account of the poverty of the see. Shelburne, he says, expected great service from him as a pamphleteer, but Watson proved from the ministerial point of view a most impracticable prelate. He immediately brought forward a scheme for improving the condition of the poorer clergy by equalizing the incomes of the bishops, the reception of which at the time may be imagined, though it was substantially the same as that carried into effect by Lord Melbourne's Government fifty years later. Watson now found that he possessed no influence with the minister, and that he had destroyed his chance of the great object of his ambition, promotion to a better diocese. Neglecting both his see and his professorship, to which latter he appointed a deputy described as highly incompetent, he withdrew to Calgarth Park, in his native county, where he occupied himself largely in forming plantations and the improvement of agriculture. He nevertheless frequently came forward as a preacher and a speaker in the House of Lords, but his only very conspicuous appearance before the public was his warm support of the prince of Wales's unqualified claim to the regency on the insanity of the king in 1788, which completed his disgrace at court. In 1796 he published his *Apology for the Bible*, in answer to Thomas Paine, at present the best known of his numerous writings. It was most effective in its day; in ours Christianity would hardly be attacked or defended by the arms employed by either disputant. Undismayed by the displeasure of the court, or perhaps hoping to overcome it, Watson continued to exert his pen with vigor, and in general to good purpose, denouncing the slave trade, advocating the union with Ireland, and offering financial suggestions to Pitt, who seems to have frequently consulted him. In 1798 his *Address to the People of Great Britain*, enforcing resistance to French arms and French principles, ran through fourteen editions, but estranged him from many old friends, who accused him, probably with injustice, of aiming to make his peace with the Government. In 1807 the advent of a Whig ministry almost brought the coveted preferment within reach. Had Dr. Markham died a few months sooner Watson would have been archbishop of York. Such a disappointment might palliate the querulous strain of his conversation and published references to himself, though it could not render it dignified or decorous. De Quincey, however, who knew the bishop personally in his latter years, while severely criticising his complaints, allows that his temper has not been soured by disappointment. "His lordship was a joyous, jovial, and cordial host." He died on July 2, 1816, having occupied his latter years in the composition and revision of an autobiography,[2] which, with all its egotism and partiality, is a valuable work, and the chief authority for his life.

As an advocate of liberal principles in church and state, Watson stands almost alone among the prelates of his day; and it cannot be said that his longing for preferment, violent and unbecoming as it was, seduced him into mean actions or unworthy compliances. His character is high enough to make it cause for regret that it should stand no higher, as it easily might if he had possessed a nicer sense of dignity and had not measured success so exclusively by the attainment of wealth and station. Hard-headed and pushing, he yet had an intellectual conscience; the two main elements of his character stood in each other's way; he failed as a courtier, and did not leave a wholly unblemished reputation as a patriot. As a bishop he neither was nor endeavored to be anything; as an ecclesiastical statesman it was his misfortune to have been born fifty years too soon. His massive but unoriginal intellect is justly characterized by De Quincey as "robust and commonplace." (R. G.)

WATT, JAMES (1736–1819), the inventor of the modern condensing steam-engine, was born at Greenock on the 19th of January, 1736. His father was a small merchant there, who lost his trade and fortune by unsuccessful speculation, and James was early thrown on his own resources. Having a taste for mechanics he made his way to London, at the age of nineteen, to learn the business of a philosophical-instrument maker, and became apprenticed to one Morgan, in whose service he remained for twelve months. From a child he had been extremely delicate, and the hard work and frugal living of his London pupilage taxed his strength so severely that he was forced at the end of a year to seek rest at home, not, however, until he had gained a fair knowledge of the trade and become handy in the use of tools. Before going to London he had made acquaintance with some of the professors in Glasgow college, and on his return to Scotland in 1756 he sought them out and obtained work in repairing astronomical instruments. He next tried to establish himself as an instrument maker in Glasgow, but the city guilds would not recognize a craftsman who had not served the full term of common apprenticeship, and Watt was forbidden to open shop in the burgh. The college, however, took him under its protection, and in 1757 he was established in its precincts with the title of mathematical-instrument maker to the university.

---

[1] [In his autobiography the bishop says his father resigned the school before his birth, and regrets "not having had a better classical foundation."—AM. ED.]

[2] [This book gives the 4th July as the date of his death. It was published by his son.—AM. ED.]

Before many months Black, the discoverer of latent heat, then lecturer on chemistry, and Robison, then a student, afterwards professor of natural philosophy, became his intimate friends, and with them he often discussed the possibility of improving the steam-engine, of which at that time Newcomen's was the most advanced type. The engine was then applied only to pumping water,—chiefly in the drainage of mines; and it was so clumsy and wasteful of fuel as to be but little used. Some early experiments of Watt in 1761 or 1762 led to no positive result, but in 1764 his attention was seriously drawn to the matter by having a model of Newcomen's engine, which formed part of the college collection of scientific apparatus, given him to repair. Having put the model in order, he was at once struck with its enormous consumption of steam, and set himself to examine the cause of this and to find a remedy.

In Newcomen's engine the cylinder stood vertically under one end of the main lever or "beam" and was open at the top. Steam, at a pressure scarcely greater than that of the atmosphere, was admitted to the under side; this allowed the piston to be pulled up by a counterpoise at the other end of the beam. Communication with the boiler was then shut off, and the steam in the cylinder was condensed by injecting a jet of cold water from a cistern above. The pressure of the air on the top of the piston then drove it down, raising the counterpoise and doing work. The injection water and condensed steam which had gathered in the cylinder were drained out by a pipe leading down into a well.

Watt at once noticed that the alternate heating and cooling of the cylinder in Newcomen's engine made it work with tedious slowness and excessive consumption of steam. When steam was admitted at the beginning of each stroke, it found the metal of the cylinder and piston chilled by contact with the condensed steam and cold injection water of the previous stroke, and it was not until much steam had been condensed in heating the chilled surfaces that the cylinder was able to fill and the piston to rise. His first attempt at a remedy was to use for the material of the cylinder a substance that would take in and give out heat slowly. Wood was tried, but it made matters only a little better, and did not promise to be durable. Watt observed that the evil was intensified whenever, for the sake of making a good vacuum under the piston, a specially large quantity of injection water was supplied.

He then entered on a scientific examination of the properties of steam, studying by experiment the relation of its density and pressure to the temperature, and concluded that two conditions were essential to the economic use of steam in a condensing steam-engine. One was that the temperature of the condensed steam should be as low as possible, 100° F. or lower, otherwise the vacuum would not be good; the other was, to quote his own words, "that the cylinder should be always as hot as the steam which entered it." In Newcomen's engine these two conditions were incompatible, and it was not for some months that Watt saw a means of reconciling them. Early in 1765, while walking on a Sunday afternoon in Glasgow Green, the idea flashed upon him that, if the steam were condensed in a vessel distinct from the cylinder, it would be practicable to make the temperature of condensation low, and still keep the cylinder hot. Let this separate vessel be kept cold, either by injecting cold water or by letting it stream over the outside, and let a vacuum be maintained in the vessel. Then, whenever communication was made between it and the cylinder, steam would pass over from the cylinder and be condensed; the pressure in the cylinder would be as low as the pressure in the condenser, but the temperature of the metal of the cylinder would remain high, since no injection water need touch it. Without delay Watt put this idea to the test, and found that the separate condenser did act as he had anticipated. To maintain the vacuum in it he added another new organ, namely, the air-pump, the function of which is to remove the condensed steam and water of injection along with any air that gathers in the condenser.

To further his object of keeping the cylinder as hot as the steam that entered it, Watt supplemented his great invention of the separate condenser by several less notable but still important improvements. In Newcomen's engine a layer of water over the piston had been used to keep it steam-tight; Watt substituted a tighter packing lubricated by oil. In Newcomen's engine the upper end of the cylinder was open to the air; Watt covered it in, leading the piston rod through a steam-tight stuffing-box in the cover, and allowed steam instead of air to press on the top of the piston. In Newcomen's engine the cylinder had no clothing to reduce loss of heat by radiation and conduction from its outer service; Watt not only cased it in non-conducting material, such as wood, but introduced a steam-jacket, or layer of steam, between the cylinder proper and an outer shell. All these features were specified in his first patent in words which have been quoted in the article STEAM-ENGINE, vol. xxii. pp. 507–8 (*q.v.*).

This patent was not obtained till January, 1769, nearly four years after the inventions it covers had been made. In the interval Watt had been striving to demonstrate the merits of his engine by trial on a large scale. His earliest experiments left him in debt, and, finding that his own means were quite insufficient to allow him to continue them, he agreed that Dr. Roebuck, founder of the Carron iron-works, should take two-thirds of the profits of the invention in consideration of his bearing the cost. An engine was then erected at Kinneil, near Linlithgow, where Roebuck lived, and this gave Watt the opportunity of facing many difficulties in details of construction. But the experiments made slow progress, for Roebuck's affairs became embarrassed, and Watt's attention was engaged by other work. He had taken to surveying, and was fast gaining reputation as a civil engineer. In 1767 he was employed to make a survey for a Forth and Clyde canal,—a scheme which failed to secure parliamentary sanction. This was followed during the next six years by surveys for a canal at Monkland, for another through the valley of Strathmore from Perth to Forfar, and for others along the lines afterwards followed by the Crinan and Caledonian Canals. He prepared plans for the harbors of Ayr, Port-Glasgow, and Greenock, for deepening the Clyde, and for building a bridge over it at Hamilton. In the course of this work he invented a simple micrometer for measuring distances, consisting of a pair of horizontal hairs placed in the focus of a telescope, through which sights were taken to a fixed and movable target on a rod held upright at the place whose distance from the observer was to be determined. The micrometer was varied in a number of ways; and another fruit of his ingenuity about the same time was a machine to facilitate drawing in perspective.

Meanwhile the engine had not been wholly neglected. Watt had secured his patent; the Kinneil trials had given him a store of valuable experience; Roebuck had failed, but another partner was ready to take his place. In 1768, Watt had made the acquaintance, though his friend Dr. Small, of Matthew Boulton, a man of energy and capital, who owned the Soho engineering works at Birmingham. Boulton agreed to buy Roebuck's share in the invention, and to join Watt in applying to parliament for an Act to prolong the term of the patent. The application was successful. In 1775, an Act was passed continuing the patent for twenty-five years. By this time the inventor had abandoned his civil engineering work and had settled in Birmingham, where the manufacture of steam-engines was begun by the firm of Boulton and Watt. The partnership was a singularly happy one. Boulton had the good sense to leave the work of inventing to Watt, in whose genius he had the fullest faith; on the other hand, his substantial means, his enterprise, resolution, and business capacity, supplied what was wanting to bring the invention to commercial success.

During the next ten years we find Watt assiduously engaged in developing and introducing the engine. Its first and for a time its only application was in pumping; it was at once put to this use in the mines of Cornwall, where Watt was now frequently engaged in superintending the erection of engines. Further inventions were required to fit it for other uses, and these followed in quick succession. Watt's second steam-engine patent is dated 1781. It describes five different methods of converting the reciprocating motion of the piston into motion of rotation, so as to adapt the engine for driving ordinary machinery. The simplest way of doing this, and the means now universally followed, is by a crank and fly-wheel; this had occurred to Watt but had meanwhile been patented by another, and hence he devised the "sun and planet wheels" and other equivalent contrivances. A third patent, in 1782, contained two new inventions of the first importance. Up to this time the engine had been single-acting; Watt now made it double-acting; that is to say, both ends of the cylinder, instead of only one, were alternately put in communication with the boiler and the condenser. Up to this time also the steam had been admitted from the boiler throughout the whole stroke of the piston; Watt now introduced the system of expansive working, in which the admission valve is closed after a portion only of the stroke is performed, and the steam enclosed in the cylinder is then allowed to expand during the remainder of the stroke, doing additional work upon the piston without making any further demand upon the boiler until the next stroke requires a fresh admission of steam. He calculated that, as the piston advanced after admission had ceased, the pressure of the steam in the cylinder would fall in the same proportion as its volume increased,—a law which, although not strictly true, does accord very closely with the actual behavior of steam expanding in the cylinder of an engine. Recognizing that this would cause a gradual reduction of the force with which the piston pulled or pushed against the beam, Watt devised a number of contrivances for equalizing the effort throughout the stroke. He found, however, that the inertia of the pump-rods in his mine engines, and the fly-wheel in his rotative engines, served to compensate for the inequality of thrust sufficiently to make these contrivances unnecessary. His fourth patent, taken out in 1784, describes the well-known "parallel motion," an arrangement of links by which the top of the piston-rod is connected to the beam so that it may either pull or push, and is at the same time guided to move in a sensibly straight line. "I have started a new hare," he writes to Boulton in June of that year; "I have got a glimpse of a method of causing a piston-rod to move up and down perpendicularly by only fixing it to a piece of iron upon the beam, without chains or perpendicular guides or untowardly frictions, arch-heads, or other pieces of clumsiness. I think it a very probable thing to succeed, and one of the most ingenious simple pieces of mechanism I have contrived."

Still a later invention was the throttle-valve and centrifugal governor, by which the speed of rotative engines was automatically controlled. One more item in the list of Watt's contributions to the development of the steam-engine is too important to be passed without mention: the indicator, which draws a diagram of the relation of the steam's pressure to its volume as the stroke proceeds, was first used by Boulton and Watt to measure the work done by their engines, and so to give a basis on which the charges levied from their customers were adjusted. It would be difficult to exaggerate the part which this simple little instrument has played in the evolution of the steam-engine. The eminently philosophic notion of an indicator diagram is fundamental in the theory of thermodynamics; the instrument itself is to the steam-engineer what the stethoscope is to the physician, and more, for with it he not only diagnoses the ailments of a faulty machine, whether in one or another of its organs, but gauges its power in health.

The commercial success of the engine was not long in being established. By 1783 all but one of the Newcomen pumping-engines in Cornwall had been displaced by Watt's. The mines were then far from thriving; many were even on the point of being abandoned through the difficulty of dealing with large volumes of water; and Watt's invention, which allowed this to be done at a moderate cost, meant for many of them a new lease of life. His engine used no more than a fourth of the fuel that had formerly been needed to do the same work, and the Soho firm usually claimed by way of royalty a sum equivalent to one-third of the saving—a sum which must have been nearly equal to the cost of the fuel actually consumed. Rival manufacturers came forward, amongst whom Bull and Hornblower are the most conspicuous names. They varied the form of the engine, but they could not avoid infringing Watt's patent by the use of a separate condenser. When action was taken against them on that ground, they retaliated by disputing the validity of the fundamental patent of 1769. In the case of Boulton and Watt *v.* Bull the court was divided on this point, but in an action against Hornblower the patent was definitely affirmed to be valid by a unanimous finding of the Court of King's Bench. This was in 1799, only a year before the monopoly expired, but the decision enabled the firm to claim a large sum as arrears of patent dues. In connection with these trials Watt himself, as well as his early friends, Black and Robison, drew up narratives of the invention of the steam-engine, which are of much interest to the student of its history.[1]

Before Watt's time the steam-engine was exclusively a steam-pump, slow-working, cumbrous, and excessively wasteful of fuel. His first patent made it quick in working, powerful, and efficient, but still only as a steam-pump. His later inventions adapted it to drive machinery of all kinds, and left it virtually what it is to-day, save in three respects. In respect of mechanical arrangement the modern engine differs from Watt's chiefly in this, that the beam, an indispensable feature in the early pumping-engines, and one which held its place long after the need for it had vanished, has gradually given way to more direct modes of connecting the piston with the crank. Another difference is in the modern use of high-pressure steam. It is remarkable that Watt, notwithstanding the fact that his own invention of expansive working must have opened his eyes to the advantage of high-pressure steam, declined to admit it into his practice. He persisted in the use of pressures that were little if at all above that of the atmosphere. His rivals in Cornwall were not so squeamish. Trevithick ventured as far as 120lb on the square inch, and a curious episode in the history of the steam-engine is an attempt which Boulton and Watt made to have an Act of Parliament passed forbidding the use of high pressure on the ground that the lives of the public were endangered. The third and only other respect in which a great improvement has been effected is in the introduction of compound expansion. Here, too, one cannot but regret to find the Soho firm hostile, though the necessity of defending their monopoly makes their action natural enough. Hornblower had in fact stumbled on the invention of the compound engine, but as his machine employed Watt's condenser it was suppressed, to be revived after some years by Woolf. In one of his patents (1784) Watt describes a steam-locomotive, but he never prosecuted this, and when Murdoch, his chief assistant (famous as the inventor of gas-lighting), made experiments on the same lines, Watt gave him little encouragement. The notion then was to use a steam-carriage on ordinary roads; its use on railways had not yet been thought of. When that idea took form later in the last years of Watt's life, the old man refused to smile upon his offspring; it is even said that Watt put a clause in the lease of his house that no steam-carriage should on any pretext be allowed to approach it.

---

[1] Another narrative of the utmost interest was written by Watt in 1814 in the form of a footnote to Robison's article "Steam-Engine," from the fourth edition of the *Encyclopædia Britannica*, which Watt revised before it was reprinted in the collected edition of Robison's works. See Robison's *Mechanical Philosophy*, vol. ii.

On the expiry in 1800 of the Act by which the patent of 1769 had been extended, Watt gave up his share in the business of engine-building to his sons, James, who carried it on along with a son of Boulton for many years, and Gregory, who died in 1804. The remainder of his life was quietly spent at Heathfield Hall,[1] his house near Birmingham, where he devoted his time, with scarcely an interruption, to mechanical pursuits. His last work was the invention of machines for copying sculpture,—one for making reduced copies, another for taking fac-similes by means of a light stiff frame, which carried a pointer over the surface of the work while a revolving tool fixed to the frame alongside of the pointer cut a corresponding surface on a suitable block. We find him in correspondence with Chantrey about this machine not many months before his death, and presenting copies of busts to his friends as the work "of a young artist just entering on his eighty-third year." His life drew to a tranquil close, and the end came at Heathfield on the 19th of August, 1819. His remains were interred in the neighboring parish church of Handsworth.

Watt was twice married,—first in 1764 to his cousin Miss Miller, who died ten years later. Of four children born of the marriage, two died in infancy; another was James, who succeeded his father in business; the fourth was a daughter who lived to maturity, but died early, leaving two children. His second wife, Miss Macgregor, whom he married before settling in Birmingham in, 1775, survived him; but her two children, Gregory and a daughter, died young.

Some of Watt's minor inventions have been already noticed. Another, which has proved of great practical value, was the letter-copying press, for copying manuscript by using a glutinous ink and pressing the written page against a moistened sheet of thin paper. He patented this in 1780, describing both a roller press, the use of which he seems to have preferred in copying his own correspondence, and also the form of screw press now found in every merchant's office.

In the domain of pure science Watt claims recognition not only as having had ideas greatly in advance of his age regarding what is now called energy, but as a discoverer of the composition of water. Writing to Priestley in April, 1783, with reference to some of Priestley's experiments, he suggests the theory that "water is composed of dephlogisticated air and phlogiston deprived of part of their latent or elementary heat." It is difficult to determine the exact meaning attached to these antiquated terms, and to say how far Watt's suggestion anticipated the fuller discovery of Cavendish. Watt's views were communicated to the Royal Society in 1783, Cavendish's experiments in 1784, and both are printed in the same volume of the *Philosophical Transactions*.

The early and middle part of Watt's life was a long struggle with poor health: severe headache prostrated him for days at a time; but as he grew old his constitution seems to have become more robust. His disposition was despondent and shrinking; he speaks of himself, but evidently with unfair severity as "indolent to excess." "I am not enterprising," he writes; "I would rather face a loaded cannon than settle an account or make a bargain; in short, I find myself out of my sphere when I have anything to do with mankind." He was a man of warm friendships, and has left a personal memorial of the greatest interest in his numerous letters to Dr. Small and others. They are full of sagacity and insight: his own achievements are told with a shrewd but extremely modest estimate of their value, and in a style of remarkable terseness and lucidity, lightened here and there by a touch of dry humor. In his old age Watt is described by his contemporaries as a man richly stored with the most various knowledge, full of anecdote, familiar with most modern languages and their literature, a great talker. Scott speaks of "the alert, kind, benevolent old man, his talents and fancy overflowing on every subject, with his attention alive to every one's question, his information at every one's command."

See J. P. Muirhead, *Origin and Progress of the Mechanical Inventions of Jaems Watt*, 3 vols., 1854 (vols. i. and ii. contain a memoir and Watt's letters; vol. iii. gives a reprint of his patent specifications and other papers); Muirhead, *Life of Watt*, 1858; Smiles, *Lives of Boulton and Watt*; Williamson, *Memorials of the Lineage, etc., of James Watt*, published by the Watt Club, Greenock, 1856; *Correspondence of the late James Watt on his Discovery of the Theory of the Composition of Water*, edited by Muirhead, 1846; Cowper, "On the Inventions of James Watt and his Models preserved at Handsworth and South Kensington," *Proc. Inst. Mech. Eng.*, 1883; article "Watt" in the *Encyclopædia Britannica*, 6th edition (1823), by James Watt, junior; Robison, *Mechanical Philosophy*, vol. ii., 1822 (letters and notes by Watt on the History of the Steam-Engine). (J. A. E.)

WATTEAU, ANTOINE (1684–1721), French painter, was born at Valenciennes in 1684. Thrown on his own resources at an early age, the boy went moneyless and ragged alone to Paris. There, after a hard struggle, he succeeded in getting work with a painter of saints for country customers, who assigned to Watteau, the future limner of gallant feastings, the repetition of dozens of St. Nicholas. The saint brought him food and shelter, and in his few holidays Watteau sketched and drew. From this shop he passed to the studio of Gillot, whose influence helped him to follow the true direction of his own special gifts, but he left him, finding employment with Audran the decorator, then at work in the Luxembourg. Then Watteau quarreled with Audran and went his way, fancying that Audran had blamed his first picture, the Departing Regiment, out of jealousy; and, flushed with success (for he had sold the work), he went off to show himself in his native Valenciennes. There Watteau produced a second work, a Regiment Halting, which also sold in Paris, so thither he returned, and welcomed by the celebrated Crozat, received fresh inspiration from his taste and the study of his immense collections. In 1709 he competed for the great prize, and standing only second, applied for a crown pension to enable him to go to Italy. As proofs of his deserts, he carried to the academy his first two pictures. His cause was warmly espoused by De la Fosse, and he was instantly made an associate of that body, becoming a full member in 1717. His diploma picture, Embarkation for the Isle of Venus, is now in the Louvre. Suffering always from lung disease, and of a highly nervous temperament, Watteau was, however, unfitted to live and work with others, and, in spite of his professional success and his assured reputation, he held himself apart, ill at ease with himself and seldom happy in his work, which suffered in sympathy with his changing moods. A visit to London further disturbed his health, and in 1721 he returned to Paris, establishing himself for a while in the house of his friend Gersaint, the picture dealer, for whom he painted a sign-board which had an extraordinary success (a fragment in the collection Schwitzer). Hoping to find rest and some alleviation to his increasing sufferings from country air, he accepted a lodging at Nogent, in the house of M. Lefebvre, which had been obtained for him through his constant friend the Abbé Haranger, canon of St. Germain l'Auxerrois. At Nogent, shortly after his arrival, on 18th July, 1721, Watteau died, having bequeathed to the abbé, to Gersaint, to M. Henin, and to M. Julienne the vast quantity of drawings which constituted almost the whole of his fortune.

No greater contrast can be found than that which Watteau's work presents to the painful condition under which he lived his life, a contrast such as that which the boyish glee of Caldecott's designs showed in comparison to the physical misery against which his gallant spirit made so brave a stand. Watteau sought refuge, as it were, from his bodily pain in that fairyland which he created, where the pompous art of the "Grand Siècle" still cumbered the ground. His work, always conceived in a poetical spirit, lived in spite of the artificial atmosphere of the mock pastoral style of the day, and lives in virtue of the exquisite precision of his observation and of the extraordinary brilliancy and lightness of his art.

---

[1] His workroom at Heathfield (now in the possession of Mr. Tangye) has been preserved full of his tools and models of his inventions. These are described, along with other Watt relics now at South Kensington, in an interesting paper by Mr. E. A. Cowper, *Proc. Inst. Mech. Eng.*, Nov., 1883.

WATTS, Isaac, (1674–1748), theologian and hymn writer, was born at Southampton, 17th July, 1674. He was the eldest of nine children, and was named after his father, who kept a boarding establishment at Southampton. The father also wrote poetry, and a number of his pieces were included by mistake in vol. i. of the son's *Posthumous Works*. Young Watts is stated to have entered on the study of the classics when only in his fifth year, and at the age of seven or eight to have composed some devotional pieces to please his mother. His nonconformity precluded him from entering either of the universities, but in his sixteenth year he went to study at an academy in London kept by the Rev. Thomas Rowe, minister of the Independent meeting at Haberdashers' Hall. In his *Improvement of the Mind* (1741) Watts has expounded his method of study, but the precepts there laid down can hardly be said to be justified by his example, for it is overwork at this period of his life that is believed to have caused the weak and uncertain health of his subsequent years. Probably it was as much from this cause as from diffidence that he deferred preaching his first sermon till the day he entered on his twenty-fourth year. Meantime he resided as tutor in the family of Sir John Hartopp at Stoke Newington, where he probably prepared the materials of his two educational works,—*Logick, or the Right Use of Reason in the Enquiry after Truth* (1725), and *The Knowledge of the Heavens and the Earth Made Easy, or the First Principles of Geography and Astronomy Explained* (1726). His *Logic*, Dr. Samuel Johnson states, "had been received into the universities," but this must be regarded rather as an indication of the decadence of logical studies there than a proof of the special excellence of the work. What merits it possesses are of a hortatory and moral kind, and, as Sir William Hamilton says, it is "not worth reading as a book of logic." In his twenty-fourth year Watts was chosen assistant to Dr. Chauncy, pastor of the Independent congregation, Mark Lane, London, and two years later he succeeded as sole pastor. The state of his health led to the appointment of an assistant in 1703. In 1704 the congregation removed to Pinner's Hall, and in 1708 they built a new meeting-house in Bury Street. In 1712 Watts took up his residence with Sir Thomas Abney of Abney Park, where he spent the remainder of his life, the arrangement being continued by Lady Abney after her husband's death. Watts preached only occasionally, devoting his leisure chiefly to the writing of hymns, the preparation of his sermons for publication, and the composition of theological works. Being little over five feet in height, and far from robust in health, he did not especially excel as an orator, although the felicity of his illustrations, his transparent sincerity, and his benevolent wisdom gave to his preaching an exceptional charm. His religous opinions were more liberal in tone than was at that time common in the community to which he belonged; his views regarding Sunday recreation and labor were scarcely of Puritanical strictness; his Calvinism was modified by his rejection of the doctrine of reprobation, and he was in the habit of representing the heaven of the Christian as affording wide scope for the exercise of the special habits and tastes formed by the employments of earth. For an estimate of Watts as a hymn writer, see HYMNS, vol. xii. p. 628. He died 25th November, 1748, and was buried at Bunhill Fields, where a tombstone was erected to his memory by Sir John Hartopp and Lady Abney. A memorial was also erected to him in Westminster Abbey, and a memorial hall, erected in his honor at Southampton, was opened 6th May, 1875.

In 1706 appeared his *Horæ Lyricæ*, of which an edition, with memoir by Robert Southey, forms vol. ix. of *Sacred Classics* (1834); in 1707 a volume of *Hymns;* in 1719 *The Psalms of David;* and in 1720 *Divine and Moral Songs for Children*. Various collected editions of his sacred poetry have been published, and in 1869 an edition appeared with music for four voices. Among the theological treatises of Watts, in addition to volumes of sermons, are *Doctrine of the Trinity* (1726); *Treatise on the Love of God and on the Use and Abuse of the Passions* (1729); *Catechisms for Children and Youth* (1730); *Essays towards a Proof of a Separate State for Souls* (1732); *Essay on the Freedom of the Will* (1732); *Essay on the Strength and Weakness of Human Reason* (1737); *Essay on the Ruin and Recovery of Mankind* (1740); *Glory of Christ as God-Man Unveiled* (1746); and *Useful and Important Questions concerning Jesus Christ* (1746). He was also the author of a variety of miscellaneous treatises. His *Posthumous Works* appeared in 1773, and a further instalment of them in 1779. Several editions of his collected works, with memoirs have also been published.

The *Life and Times* of Watts by Milner appeared in 1834; a life is also included in Johnson's *Lives of the Poets.*

WAVE. By this term is commonly understood a state of disturbance which is propagated from one part of a medium to another. Thus it is energy which passes, and not matter,—though in some cases the wave permanently displaces, usually to a small amount only, the medium through which it has passed. Currents, on the other hand, imply the passage of matter associated with energy.

The subject is one which, except in a few very simple or very special cases, has as yet been treated only by approximation even when the most formidable processes of modern mathematics have been employed,—so that this sketch, in which it is desired that as little as possible of higher mathematics should be employed, must be confined mainly to the statement of results. And the effects of viscosity, though very important, cannot be treated.

There are few branches of physics which do not present us with some forms of wave, so that the subject is a very extensive one: tides, rollers, ripples, bores, breakers, sounds, radiations (whether luminous or obscure), telegraphic and telephonic signalling, earthquakes, the propagation of changes of surface-temperature into the earth's crust—all are forms of wave-motion. Several of these phenomena have been treated in other parts of this work, and will now be but briefly referred to; others require more detailed notice.

When a medium is in stable equilibrium, it has no kinetic energy, and its potential energy is a minimum. Any local disturbance, therefore, in general involves a communication of energy to part of the medium, and it is usually by some form of wave-motion that this energy spreads to other parts of the medium. The mere withdrawal of a quantity of matter (as by lifting a floating body out of still water), local condensation of vapor in the air, the crushing of a hollow shell by external pressure, the change of volume resulting from an explosion or from the sudden vaporization of a liquid—are known to all as common sources of violent wave-disturbance.

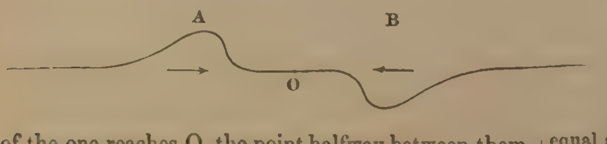
Waves may be *free* or *forced*. In the former class the disturbance is produced once for all, and is then propagated according to the nature of the medium and the form of the disturbance. Or the disturbance may be continued, provided the waves travel faster than does the centre of disturbance. In forced waves, on the other hand, the disturbing force continues to act so as to modify the propagation of the waves already produced. Thus, while a gale is blowing, the character of the water-waves is continually being modified; when it subsides, we have regular oscillatory waves, or rollers, for the longer ones not only outstrip the shorter but are less speedily worn down by fluid friction. The huge mass of water which some steamers raise, especially when running at a high speed, is an excellent example of a forced wave. The ocean-tide is mainly a forced wave, depending on the continued action of the moon and sun; but the tide-wave in an estuary or a tidal river is practically free,—being almost independent of moon and sun, and depending mainly upon the configuration of the channel, the rate of the current, and the tidal disturbance at the mouth.

In what follows we commence with a special case of extreme simplicity, where an *exact* solution is possible. This will be treated fully, partly on account of its own interest, partly because its results will be of material assistance in some of the less simple, and sometimes apparently quite different, cases which will afterwards come up for consideration.

(1) *Transverse Waves on a Stretched Wire.*—In the article MECHANICS, § 265, it has been proved by the most elementary considerations that an inextensible but flexible rope, under uniform tension, when moving at a certain definite rate through a smooth tube of any form, exerts no pressure on the interior of the tube. In fact, the rope must press with a force T/r (where T is the tension and r the radius of curvature) on the unit of length in consequence of its tension, and with a force $-\mu v^2/r$ (where v is the speed, and μ the mass of unit length) in consequence of its inertia. That there may be no pressure on the tube, *i.e.*, that it may be dispensed with, we must therefore have $T - \mu v^2 = 0$, or $v = \sqrt{T/\mu}$. From this it follows that a disturbance of *any* form (of course with continuous curvature) runs along a stretched rope at this definite rate, and is unchanged during its progress. In the proof, the influence of gravity was left out of consideration, and this result may therefore be applied to the motion of a transverse disturbance along a stretched wire, such as that of a pianoforte, where the tension is very great in comparison with the weight of the wire. But the italicised word *any*, above, gives an excellent example of one of the most difficult parts of the whole subject, viz., the possibility of a *solitary* wave. This is a question upon which we cannot here enter.

If we restrict ourselves to slight disturbances only, theory points out and trial verifies that they are superposable. In fact, in the great majority of investigations which have been made with regard to waves, the disturbances have been assumed to be slight, so that we can avail ourselves of the principle of *superposition of small motions* (MECHANICS, § 73), which is merely an application of the mathematical principle of "neglecting the second order of small quantities." The verification by *trial* is given at once by watching how the ring-ripples produced by two stones thrown into a pool pass through one another without any alteration; that by *observation* is evident to any one who sees an object in sunlight, when the whole intervening space is full of intense wave-motion.

Returning to our wire, let us confine ourselves to a small transverse disturbance, in one plane, and try to discover what happens when the disturbance reaches one of the fixed ends of the wire. Whether a point of the wire be fixed or not does not matter, provided it *do not move.* In the figure below, two disturbances are shown, moving in opposite directions (and of course with equal speed). Of these, either is the *perversion*, as well as the inversion, of the other. When any part of the one reaches O, the point halfway between them, so as to displace it upwards, the other contributes an exactly equal displacement downwards. Thus O remains permanently at rest, while the two waves pass through it without affecting one another; and we may therefore assert that the wave A when it reaches the end of the wire is reflected as B, or rather that each part of A when it reaches O goes back as the corresponding part of B. B, in the same way, is seen to be reflected from O as A.



Now we can see what happens with a pianoforte wire. Any disturbance A is reflected from one end O as B, and at the other end is reflected as A again. Hence the state of the wire, whatever it may be, recurs *exactly* after such an interval as is required for the disturbance to travel, twice over, the length of the string.

Remembering that the displacements are supposed to be very small, our fundamental result may now be expressed by saying that the force acting on unit length of the disturbed wire, to restore it to its undisturbed position, is T/r or $\mu v^2/r$. Thus the *ratio of the acceleration of each element to its curvature is the square of the rate of propagation of the wave.* It will be shown below that this is the immediate interpretation of the differential equation of the wave-motion.

Let us express the position of a point of the wire, when undisturbed, by x its distance (say) from one end. Let y represent its transverse displacement at time t. Then, bearing in mind that the disturbance travels with a constant speed v, the nature of the motion, so far as we have yet limited it, will be expressed by saying that the value of y, at x, at time t, will be the value of y, at $x + v\tau$, at time $t + \tau$; or, simply,

$$y = f(vt - x).$$

For this expression, whatever be the function f, is unchanged in value, if $t + \tau$ be put for t, and $x + v\tau$ for x; and no other expression possesses this special property. If there be a disturbance running the opposite way along the wire, we easily see that it will be represented by an expression of the form

$$F(vt + x).$$

These disturbances are superposable, so that

$$y = f(vt - x) + F(vt + x) \quad \ldots \ldots \quad (1)$$

expresses the most general state of disturbance which the wire can suffer under the limitations we have imposed. Before going farther we may use this to reproduce the results given above.

Now $x = 0$ is one end of the wire, and *there* y is necessarily always zero. Hence

$$0 = f(vt) + F(vt),$$

so that the functions f and F differ only in sign. This condition, inserted in (1), gives us at once the state of matters indicated by the cut above.

If $x = l$ be the other end of the wire, we have the new condition

$$0 = f(vt - l) - f(vt + l).$$

The meaning of this is simply that the disturbance is periodic, the period being $2l/v$, the other result already obtained.

Fourier's theorem (See HARMONIC ANALYSIS, or MECHANICS, § 67) now shows that the expression f may be broken up into one definite series of sines and cosines, whence the usual results as to the various simple sounds which can be produced, together or separately, from a free stretched string.

It may be asked, and very naturally, How can this explanation of the nature of all possible transverse motions of a harp or pianoforte wire, as the result of sets of equal disturbances *running along it* with constant speed, be consistent with the appearance which it often presents of vibrating as a whole, or as a number of equal parts separated from one another by *nodes* which remain apparently at rest in spite of the disturbances to which, if the explanation be correct, they are constantly subjected? The answer is given at once by a consideration of the expression

$$y = \sin\frac{i\pi}{l}(vt - x) - \sin\frac{i\pi}{l}(vt + x)$$

(where i is any integer), which is a particular case of the general expression (1), limited to the circumstances of a wire of length l. This indicates, as we have seen, two exactly similar and equal sets of simple harmonic waves running simultaneously, with equal speed, in opposite directions along the wire. By elementary trigonometry we can put the expression in the form

$$y = -2\sin\frac{i\pi x}{l}\cos\frac{i\pi vt}{l}.$$

This indicates—*first*, that the points of the string where x has the values

$$0\,,\, l\, i\,,\, 2l\, i\,,\, \ldots\,,\, l$$

remain constantly at rest (these are the ends, and the $i-1$ equidistant nodes by which the wire is divided into i practically independent parts); *second*, that the form of the wire, at any instant, is a curve of sines, and that the ordinates of this curve increase and diminish simultaneously with a simple harmonic motion—the wire resuming its undisturbed form at intervals of time l/iv.

This discussion has been entered into for the purpose of showing, from as simple a point of view as possible, the production of a *stationary* or *standing* wave. The same principle applies to more complex cases, so that we need not revert to the question.

Recurring to the general expression for y in (1), it is clear that if we differentiate it twice with respect to t, and again twice with respect to x, the results will differ only by the factor v^2 which occurs in each term of the first. Thus

$$\frac{d^2y}{dt^2}=v^2\frac{d^2y}{dx^2}=\frac{\mathrm{T}}{\mu}\frac{d^2y}{dx^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

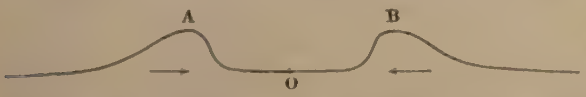
is merely another way of writing (1). But in this new form it admits of the immediate interpretation given above in italics. For $\frac{d^2y}{dt^2}$ is the acceleration, and $\frac{d^2y}{dx^2}$ the curvature.

(2) *Longitudinal Waves in a Wire or Rod.*—If the displacements of the various parts of the wire be longitudinal instead of transverse, we may still suppose them to be represented graphically by the figure above—by laying off the longitudinal displacement of each point in a line through that point, in a definite plane, and perpendicular to the wire. In the figure a displacement to the right is represented by an upward line, and a displacement to the left by a downward line. The extremities of these lines will, in general, form a curve of continued curvature. And it is easy to see that the tangent of the inclination of the curve to the axis (*i.e.*, its steepness at any point) represents the elongation of unit length of the wire at that point, while the curvature measures the rate at which this elongation increases per unit of length. The force required to produce the elongation bears to the elongation itself the ratio E, viz., Young's modulus. The acceleration of unit length is the *change* of this force per unit length, divided by μ. Hence, by the italicized statement in (1), we have $v=\sqrt{\mathrm{E}/\mu}$ (MECHANICS, § 270). All the investigations above given apply to this case also, and their interpretations, with the necessary change of a word or two, remain as before.

Thus, according to our new interpretation of the figure, the front part of A indicates a wave of compression, its hind part one of elongation, of the wire—the displacement of every point, however, being to the right. B is an equal and similar wave, its front being also a compression, and its rear an elongation, but in it the displacement of each point of the wire is to the left.

Hence the displacements of O continually compensate one another; and thus a wave of compression is reflected from the fixed end of the wire as a wave of compression, but positive displacements are reflected as negative.

If we now consider a free rod, set into longitudinal vibration by friction, we are led to a particular case of reflection of a wave from a *free* end. The condition is obviously that, at such a point, there can be neither compression nor elongation. To represent the reflected wave we must therefore take B of such a form that each part of it, when it meets at O the corresponding part of A, shall just annul the compression. On account of the smallness of the displacements, this amounts to saying that the successive parts of B must be equally inclined to the axis with the corresponding parts of A, but *they must slope the other way.* Thus the proper figure for this case is and the interpretation is that a wave of compression is reflected from a free end as an equal and similar wave of elongation; but the disturbance at each point of the wire in the reflected wave is to the same side of its equilibrium position as in the incident wave.



This enables us to understand the nature of reflection of a wave of sound from the end of an open organ pipe, as the former illustration suited the corresponding phenomenon in a close one.

(3) *Waves in a Linear System of Discrete Masses.*—Suppose the wire above spoken of to be massless, or at least so thin, and of such materials, that the whole mass of it may be neglected in comparison with the masses of a system of equal pellets, which we now suppose to be attached to the wire at equal distances from one another. The weights of these pellets may be supported by a set of very long vertical strings, one attached to each, so that the arrangement is unaffected by gravity. The wire may be supposed to be stretched, as before, with a definite tension which is not affected by small transverse disturbances. We will take the case of transverse disturbances only, but it is easy to see that results of precisely the same form will be obtained for longitudinal disturbances. A moment's thought will convince the reader that there must be a limit to the frequency of the oscillations which can be transmitted along a system like this, though there was none such with the continuous wire. It is not difficult to find this limit.

Let the transverse displacement, at time t, of the n^{th} pellet of the series, be called y_n; and let T be the tension of the wire, m the mass of a pellet, and a the distance from one pellet to the next. Then the equation of motion is obviously

$$m\frac{d^2y_n}{dt^2}=\mathrm{T}\frac{y_{n+1}-y_n}{a}-\mathrm{T}\frac{y_n-y_{n-1}}{a},$$
$$=\frac{\mathrm{T}}{a}\left(\mathrm{D}-2+\frac{1}{\mathrm{D}}\right)y_n\,,$$

where D stands for $\varepsilon^{a\frac{d}{dx}}$.

[We remark in passing that, if a be very small, this equation tends to become

$$m\frac{d^2y}{dt^2}=\frac{\mathrm{T}}{a}a^2\frac{d^2y}{dx^2}.$$

But in this case we have ultimately $m=a\mu$; so that we recover the equation for transverse vibrations of a uniform wire.]

Suppose

$$y_n=\mathrm{A}\cos(pt-qx)$$

(where $x=na$) to be a possible free motion of the system. When this value is substituted in the equation above it gives

$$-mp^2\cos(pt-qx)=\frac{\mathrm{T}}{a}\Big[\cos(pt-q\overline{x+a})+\cos(pt-q\overline{x-a})$$
$$-2\cos(pt-qx)\Big]$$
$$=-\frac{2\mathrm{T}}{a}\cos(pt-qx)\,.\,(1-\cos qa),$$

so that

$$mp^2=\frac{4\mathrm{T}}{a}\sin^2 qa/2.$$

It appears from the form of this expression that the greatest value of p is $2\sqrt{\mathrm{T}/am}$; or $2v/a$, if v be the speed of a disturbance in a uniform wire under the same tension, and of the same actual mass per unit of length. The time of oscillation of a pellet is $2\pi/p$, and cannot therefore be less than

$$\pi\sqrt{am/\mathrm{T}}\text{, or }\pi a/v.$$

The result is that, if v be the speed of propagation of a disturbance in a uniform wire with the same tension and same mass, the period of the quickest simple harmonic transverse oscillation which can be freely transmitted in such a system is π times the time of running from one pellet to the next with speed v.

Instead of pellets on a tended wire, we might have a series of equal bar magnets, supported horizontally at proper distances from one another, in a line. The magnetic forces here take the place of the tension; and by arranging the magnets with their like poles together, *i.e.*, by inverting the alternate ones, we can produce the equivalent of pressure instead of tension along the series. If the magnets have each bifilar suspension, their masses will come in, as well as their moments of inertia, in the treatment of transverse disturbances.

This question is closely connected with Stokes's explanation of fluorescence (see LIGHT, vol. xiv. p. 607), for the effect of a disturbing force, of a shorter period than the limit given above, applied continuously to one of the pellets, would be to accumulate energy mainly in the immediate neighborhood; and this, if we suppose the disturbing force to cease, would be transmitted along the system in waves of periods equal at least to the limit. These would correspond to light of lower refrangibility than the incident, but having as characteristics a definite upper limit of refrangibility.

Such investigations, with their results, prepare us to expect that the usual mode of investigating the propagation of sound, to which we proceed, cannot be correct in the case of exceedingly high notes if the medium consist of discrete particles.

(4) *Waves of Compression and Dilatation in a Fluid; Sound; Explosions.*—Consider the case of plane waves, where each layer of the medium moves perpendicularly to itself, and therefore may suffer dilatation or compression. The case is practically the same as that treated in (2) above, and can be represented by the same graphic method. For we may obviously consider only the matter contained in a *rigid* cylinder of unit sectional area, whose axis is parallel to the displacements. The only point of difference is in the law connecting pressure and consequent compression, and that, of course, depends upon the properties of the medium considered.

(*a*) If the medium be a liquid, such as water, for instance, the compression may be taken as proportional to the pressure. Thus the acceleration on unit length of the column, multiplied by its mass (which in this case is simply the density of the medium), is equal to the increase of pressure per unit length, *i.e.*, to the increase of condensation per unit length, multiplied by the resistance to compression, R. Thus the speed of the wave is $\sqrt{R/\rho}$, which is exactly analogous to the forms of (1) and (2). The density, ρ, of water is 62.3 ℔ per cubic foot, and for it R is about 20,000 atmospheres at 0° C., so the speed of sound at that temperature is about 4700 feet per second.

That even intense differences of pressure take time to adjust themselves over very short distances in water was well shown by the damage sustained by the *open* copper cases of those of the "Challenger" thermometers which were crushed by pressure in the deep sea. When a strong glass shell (containing air only) is enclosed in a stout open iron tube whose length is two or three of its diameters, and is crushed by water pressure, the tube is flattened by excess of external pressure before the relief can reach the outside.

(*b*) In the case of a gas, such as air, we must take the adiabatic relation between pressure and density. The pressure increases faster than, instead of at the same rate with, the density, as it would do if the gas followed Boyle's law. Thus the changes of pressure, instead of being equal to the changes of compression (multiplied by the modulus), exceed them in the proportion of the specific heat at constant pressure (K) to that at constant volume (N). Thus the speed of sound is $\sqrt{K/N.p/\rho}$, where p is the pressure and ρ the density in the undisturbed air. The ratio of the two latter quantities, as we know, is very approximately proportional to the absolute temperature.

The questions of the gradual change of type or the dying away even of plane waves of sound, whether by reason of their form, by fluid friction, or by loss of energy due to radiation, are much too complex to be treated here.

In all ordinary simple sounds even of very high pitch the displacements are extremely small compared with the wave length, so that the approximate solution gives the speed with considerable accuracy. And a very refined experimental test that this speed is independent of the pitch consists in listening to a rapid movement played by a good band at a great distance. But there seems to be little doubt that, under certain conditions at least, very loud sounds travel a great deal faster than ordinary sounds.

The above investigation gives the speed of sound relatively to the air. Relatively to the earth's surface, it has to be compounded with the motion of the air itself. But, as the speed of wind usually increases from the surface upwards, at least for a considerable height, the front of a sound-wave, moving *with* the wind, leans forward, and the sound (being propagated perpendicularly to the front) moves downwards; if *against* the wind, upwards.

In the case of a disturbance in air due to a very sudden explosion, as of dynamite or as by the passage of a flash of lightning, it is probable that for some distance from the source the motion is of a projectile character; and that part at least of the flash is due to the heat developed by practically instantaneous and very great compression of each layer of air to which this violent motion extends.

(5) *Gravitation and Surface-Tension Waves in Liquids.*—Leaving out of consideration, as already sufficiently treated in a special article, the whole subject of TIDES, whether in oceans or in tidal rivers, there remain many different forms of water-waves all alike interesting and important. The most usual division of the free waves is into long waves, oscillatory waves, and ripples. The first two classes run by gravity, the third mainly by surface-tension (see CAPILLARY ACTION). But, while the long waves agitate the water to nearly the same amount at all depths, the chief disturbance due to oscillatory waves or to ripples is confined to the upper layers of the water, from which it dies away with great rapidity in successive layers below. We will treat of these three forms in the order named.

(6) *Long Waves.*—The first careful study of these waves was made by Scott RUSSELL (*q.v.*) in the course of an inquiry into traffic on canals. He arrived at the remarkable result that there is a definite speed, depending on the depth of the water, at which a horse can draw a canal-boat more easily than at any other speed, whether less or greater. And he pointed out that, when the boat moves at this speed, it agitates the water less, and therefore damages the banks less, than at any lower. This particular speed is thus, in fact, that of free propagation of the wave raised by the boat; and, when the boat rides, as it were, on this wave, its speed is maintained with but little exertion on the part of the horse. If the boat be made to move slower, it leaves behind it an ever-lengthening procession of waves, of course at the expense of additional labor on the part of the horse.

The theory of the motion of such a wave is based on the hypothesis that all particles in a transverse section of the canal have, at the same instant, the same horizontal speed. However great this horizontal motion may be, the vertical motion of the water may be very small, for it depends on the change of horizontal speed from section to section only. In the investigation which follows, the energy of this vertical motion will be neglected (even at the surface, where it is greatest) in comparison with that of the horizontal motion. The hypothesis is proved to be well grounded by the actual observation of the motion of the water when a long wave of slight elevation or depression passes. A long box, with parallel sides of glass, partly filled with water, represents the canal; and the wave is produced by slowly and slightly tilting the box, and at once restoring it to the horizontal position. The nature of the motion of the water is shown by particles of bran suspended in it. Such an apparatus may be usefully employed in verifying the theoretical result below, as to the connection between the speed of the wave and the depth of the water,—observations of the passage of the crest being made with great exactness by means of a ray of light reflected from the surface of the water in a vertical plane parallel to the length of the canal. It may also be employed, by tilting it about an inclined position, for the study of the changes which take place in the wave as it passes from deeper to shallower water, or the reverse.

The statement of (1) above is immediately applicable to this question. For, if h be the (undisturbed) depth of the water, ρ its density, y and y' the elevations in two successive transverse sections at unit distance from one another, the difference of pressures (at the same level) in the two sections is $g\rho(y'-y)$. The acceleration of a horizontal cylinder of unit section is the difference of pressures divided by ρ. But the whole depth is increased at each point in proportion as the thickness of a transverse slice is diminished. Hence, by the reasoning in (2) above,

$$\frac{g\rho(y'-y)}{\rho}=\frac{p'-p}{\rho}=v^2\frac{y'-y}{h},$$

or

$$v^2=gh;$$

and the speed of propagation of the wave is that which a stone would acquire by falling through half the depth of the water. That the speed ought to be independent of the density of the liquid is clear from the fact that it is the weight of the disturbed portion which causes the motion, and that this (for equal waves in different liquids) changes proportionally to the mass to be moved.

Since we have made no hypothesis as to the form of the wave, our only assumptions being that the vertical motion is not only small in comparison with the depth, but inconsiderable in comparison with the horizontal motion, while the latter is the same at all depths in any one transverse section, it is clear that, under the same limitations, a wave of depression will run at the same speed as does a wave of elevation.

A solitary wave of elevation obviously carries across any fixed transverse plane a quantity of water equal to that which lies above the undisturbed level. If H be the mean height of this raised water, b the breadth of the canal (supposed rectangular), and λ the length of the wave, the volume of this water is $b\lambda\mathrm{H}$. But all particles in the transverse section behave alike; and, when the wave has passed, the particles in *all* transverse sections have been treated alike. Hence the final result of the passage of the wave is that the whole of the water of the canal has been translated, in the direction of the wave's motion, through the space $b\lambda\mathrm{H}/bh$, or $\lambda\mathrm{H}/h$. If the wave had been one of depression, the translation of the water would have been in the opposite direction to that of the wave's motion. Hence, when the wave consists of an elevation followed by a depression of equal volume, it leaves the water as it found it. Thus any permanent displacement of the water is due to inequality of troughs and crests.

A hint, though a very imperfect one, as to the formation of breakers on a gently sloping beach, is given by considering that in shallow water the front and rear of an ordinary surface-wave must move at different rates, the front being in shallower water than the rear and therefore allowing the rear to gain upon it.

(7) *Oscillatory Waves.*—The typical example of these waves is found in what is called a "swell" or the regular rolling waves which continue to run in deep water after a storm. Their character is essentially periodic, and this feature at once enables us to select from the general integrals of the equations of non-rotatory fluid-motion the special forms which we require. The investigation may, without sensible loss of completeness for application, be still further simplified by the assumption that the disturbance is two-dimensional, *i.e.*, that the motion is precisely the same in any two vertical planes drawn parallel to the direction in which the waves are travelling. The investigation is, unfortunately, very much more simple in an analytical than in a geometrical form.

If the axis of x be taken in the surface of the undisturbed water, in the direction in which the waves are travelling, and that of y vertically *downwards*, the equation for the velocity-potential (see HYDROMECHANICS) is simply

$$\frac{d^2\phi}{dx^2}+\frac{d^2\phi}{dy^2}=0.$$

This is merely the "equation of continuity,"—the condition that no liquid is generated, and none annihilated, during the motion.

The type of solution we seek, as above, is represented by

$$\phi=\mathrm{Y}\cos(mt-nx),$$

where Y depends on y alone. If this can be made to satisfy the equation of continuity, we may proceed to further tests and restrictions of it. Substitution leads to

$$\frac{d^2\mathrm{Y}}{dy^2}-n^2\mathrm{Y}=0,$$

so that $\mathrm{Y}=\mathrm{A}\varepsilon^{ny}+\mathrm{B}\varepsilon^{-ny}$, where A and B are arbitrary constants.

(*a*) If the depth of the water be unlimited, the value of A must be zero, for otherwise we should be dealing with disturbances which increase, without limit, as we go farther down. Hence, in this case, a particular integral of the equation, corresponding to a disturbance which can exist by itself, is

$$\phi=\mathrm{B}\varepsilon^{-ny}\cos(mt-nx).$$

We will now avail ourselves of the supposition under which, as we have seen, disturbances are necessarily superposable, *i.e.*, assume terms in B^2 to be negligible. The ordinary kinetic equation (HYDROMECHANICS) then becomes

$$\mathrm{C}+p/\rho=gy-\left(\frac{d\phi}{dt}\right)$$
$$=gy+m\mathrm{B}\varepsilon^{-ny}\sin(mt-nx).$$

If we differentiate this expression with regard to t, and apply the result to the surface only, where p is constant, and remember that $\frac{dy}{dt}=\left(\frac{d\phi}{dy}\right)$, we have simply

$$0=-ng+m^2,$$

which is the condition that no water *crosses* the bounding surface. This determines n, without ambiguity, when m is given, and thus gives a relation between the period of a wave and its length, or between the period or the length and the speed of propagation. For we may write

$$mt-nx=\frac{2\pi}{\lambda}(vt-x),$$

where λ is the wave-length, and v the speed; so that

$$m=\frac{2\pi v}{\lambda},\quad n=\frac{2\pi}{\lambda}.$$

Thus we have

$$v^2=\frac{g\lambda}{2\pi},$$

And the longer waves move faster, even when the vertical displacement is small in both. This is quite different from the result for sound-waves.

The components of the velocity of the particle of water whose mean position is x, y are

$$\left(\frac{d\phi}{dx}\right)=\mathrm{B}n\varepsilon^{-ny}\sin(mt-nx),\text{ parallel to }x,$$

and

$$\left(\frac{d\phi}{dy}\right)=-\mathrm{B}n\varepsilon^{-ny}\cos(mt-nx),\text{ parallel to }y.$$

Hence the path is a circle whose radius is

$$\mathrm{B}\frac{n}{m}\varepsilon^{-ny},\text{ or }\mathrm{B}\frac{m}{g}\varepsilon^{-ny}.$$

At the surface this is $\mathrm{B}m/g$, as in fact we see at once by the equation for the pressure, which gives for the form of the surface

$$\mathrm{C}=g\eta+m\mathrm{B}\sin(mt-nx).$$

Each surface-particle is at the highest point of its circular path, and moving forwards, when the crest of the wave passes it. When the trough passes, it is at the lowest point of its circle and moving backwards. The radii of the circles diminish in geometrical progression at depths increasing in arithmetical progression. The factor is $\varepsilon^{-ny}=\varepsilon^{-2\pi y/\lambda}$, so that at a depth of *one* wave-length only the disturbance is reduced to $\varepsilon^{-2\pi}$ or about 1/535 of its surface-value.

From the investigation above we see that Atlantic rollers, of a wave-length of (say) 300 feet, travel at the rate of about 40 feet per second, or 27 miles an hour. But, even if they be of 40 feet height from trough to crest (which is probably an exaggerated estimate), the utmost disturbance of a water particle at a depth of 300 feet is not quite half an inch from its mean position. This shows, in a very striking manner, what a mere surface-effect is in this way due to winds, and how the depths of the ocean are practically undisturbed by such causes.

This investigation has been carried to a second, and even to a third, approximation by Stokes, with the result that the form of a section of the surface is no longer the curve of sines, in which the crests and troughs are equal. The crests are steeper and higher, and the troughs wider and shallower, than the first approximation shows. Also the forward horizontal motion of each particle under the crest is no longer quite compensated for by its backward motion under the trough, so that what sailors call the "heave of the sea" is explained. The water is permanently displaced forwards by each succeeding wave. But this effect, like the whole disturbance, is greatest in the surface-layer and diminishes rapidly for each lower layer. The third approximation shows that the speed of the waves is greater than that above assigned, by a term depending on the square of the ratio of the height to the length of a wave.

(*b*) When the depth of the water is limited, we cannot make the simplification adopted in the last investigation.

If h be the depth of the water, our condition is that the vertical motion vanished at that depth, and the relation between m and n is now

$$m^2 = ng(\varepsilon^{nh} - \varepsilon^{-nh})/(\varepsilon^{nh} + \varepsilon_{-nh}).$$

If h be regarded as infinite this gives as before

$$m^2 = ng.$$

If, on the other hand, h be small compared with the wave-length, the equation approximates to

$$m^2 = n^2gh,$$

or

$$v^2 = gh;$$

and we have the formula for long waves again. Thus the expression above includes both extremes,—though, so far as long waves go, it limits them to harmonic forms of section.

The surface-section is still the curve of sines, but the paths of the individual particles are now ellipses whose major axes are horizontal. Both axes decrease with great rapidity for particles considered at gradually increasing depths; but the minor axes diminish faster than the major, so that the particles at the bottom oscillate in horizontal lines.

(8) *Ripples.*—Stokes in 1848 pointed out that the surface-tension of a liquid should be taken account of in finding the pressure at the free surface, but this seems not to have been done till 1871, when W. Thomson discussed its consequences. If T be the surface-tension, and r the radius of curvature of the (cylindrical) surface, in the case of oscillatory waves, the pressure at the free surface must be considered as differing from that in the air by the quantity T/r (CAPILLARY ACTION). As T/$g\rho$ is usually a small quantity, this term will be negligible unless r is very small. If the waves be oscillatory, this means that their lengths must be very short, so that the depth of the fluid may be treated as infinite in comparison.

The curvature is practically $d^2\eta/dx^2$, because η/λ is small; so that the term $-\mathrm{T}d^2\eta/dx^2$ must be introduced into the kinetic equation along with p. The result is that

$$m^2 = ng + \frac{n^3\mathrm{T}}{m\rho},$$

or

$$v^2 = \frac{g\lambda}{2\pi} + \frac{2\pi}{\lambda}\frac{\mathrm{T}}{\rho}.$$

Thus the speed is, in all cases, increased by the surface-tension; and the more so the shorter is the wave-length. Hence, as the speed increases indefinitely with increase of wave-length when gravity alone acts, and also increases indefinitely the shorter the wave when surface-tension alone acts, there must be a *minimum* speed, for some definite wave-length, when both causes are at work. It is easily seen that v^2 is a minimum when

$$\lambda = \lambda_0 = 2\pi\sqrt{\mathrm{T}/g\rho},$$

and that the corresponding value of v^2 is

$$2\sqrt{g\mathrm{T}/\rho}.$$

In the case of water the value of λ_0 is about 0.68 inch, and v_0 is 0.76 in feet-seconds, nearly.

This slowest-moving oscillatory wave may therefore be regarded as the limit between waves proper and ripples. That ripples run faster the shorter they are is easily seen by watching the apparently rigid pattern of them which precedes a body moving uniformly through still water. The more rapid the motion the closer do the ripple-ridges approach one another. Excellent examples of ripples are produced by applying the stem of a vibrating tuning-fork to one side of a large rectangular box full of liquid. From the pitch of the note, and the wave-length of the ripples, we can make (by the use of the above formula) an approximate determination of surface-tension, a quantity somewhat difficult to measure by statical processes.

The conditions of production of ripples by wind, or generally in a surface of separation of two fluids, each of which has any motion parallel to this surface, are given in HYDROMECHANICS.

(9) *Interference of Waves.*—While the disturbances considered are so small as to be superposable, *i.e.*, independent of one another, the effect of superposition is merely a kinematical question, and, as such, has been very fully treated under MECHANICS (§§ 56–67). See also ACOUSTICS, LIGHT, and WAVE THEORY. Thus ripple-patterns, ordinary beats of musical sounds, composition of lunar and solar ocean tides, diffraction, phenomena of polarized light in crystals or in transparent bodies in the magnetic field, etc., are all, in *principle* at least, simple kinematical consequences of superposition. But the phenomena called Tartini's beats, breakers, a bore, a jabble, and (generally) cases in which a sufficient approximation cannot be obtained by omitting powers of the displacements higher than the first, are not of this simple character.

As a single illustration, take one case of the first of these phenomena. The *fact* to be explained is that when two pure musical sounds, of frequencies 2 and 3 (say), that is, forming a "perfect fifth," are sounded together, we hear in addition to them a graver note, viz., that of which the first sound is the octave and the second the twelfth. When a resonator, carefully tuned to this graver note, is applied to the ear the note is usually not heard. Hence Helmholtz attributes its production to the fact that the drum of the ear (in consequence of the attachments of the ossicles) has different elastic properties for inward and for outward displacements.

The force tending to restore the drum from a displacement x may therefore be represented approximately by

$$-p^2x + qx^2.$$

Thus, when the drum is exposed to the two sounds above mentioned, its equation of motion is

$$\frac{d^2x}{dt^2} + p^2x = qx^2 + a\sin 3mt + b\sin(2mt + \beta).$$

By successive approximations, it is found that there is a term in the value of x of the form

$$\frac{abq\cos(mt - \beta)}{(p^2 - 9m^2)(p^2 - 4m^2)(p^2 - m^2)},$$

which is the "difference-tone" referred to. This, of course, is communicated to the internal ear.

Helmholtz points out, however, that such sounds may be produced objectively, provided the interfering disturbances are sufficiently great. No one seems yet to have obtained any really accurate notion of the smallness of the disturbances of air which can be heard as sound. That they are excessively small has long been shown by many processes, but even more perfectly by the comparatively recent invention of the telephone.

(10) *Waves in an Elastic Solid.*—Some of the more elementary parts of this very difficult question have been treated from a theoretical point of view in the article ELASTICITY. From an observational and experimental point of view some are treated under EARTHQUAKE. See also LIGHT, and WAVE THEORY, for the luminiferous medium appears to behave like an elastic solid.

(11) *Waves of Temperature and of Electric Potential.*—In HEAT (§ 78), and specially in the mathematical appendix to that article, will be found Fourier's treatment of heat-waves produced by periodic sources of various characters. It is sufficient to call attention here to the form of the equation for the linear motion of heat (which is the same as that for electricty and for diffusion), viz.,

$$c\frac{dv}{dt}=\frac{d}{dx}\left(k\frac{dv}{dx}\right),$$

where v represents temperature, c specific heat, and k thermal conductivity.

When c and k are constants, this takes the very simple form

$$\frac{dv}{dt}=\kappa\frac{d^2v}{dx^2}.$$

If plane harmonic waves of the type

$$v=\mathrm{X}\cos(mt-nx)$$

are to be transmitted, we must have simultaneously

$$\frac{d^2\mathrm{X}}{dx^2}-n^2\mathrm{X}=0,\ 2\kappa n\frac{d\mathrm{X}}{dx}=-m\mathrm{X}.$$

The first gives

$$\mathrm{X}=\mathrm{A}\varepsilon^{nx}+\mathrm{B}\varepsilon^{-nx};$$

and the second, by means of this, gives

$$2\kappa n^2(\mathrm{A}\varepsilon^{nx}-\mathrm{B}\varepsilon^{-nx})=-m(\mathrm{A}\varepsilon^{nx}+\mathrm{B}\varepsilon^{-nx}).$$

Thus A vanishes, which implies that the amplitude of the waves must continuously diminish as they progress. Also

$$2\kappa n^2=m,$$

so that

$$v=\mathrm{B}\varepsilon^{-nx}\cos(2\kappa n^2t-nx).$$

If the conductivity be not constant, then, even in the simple case of

$$k=k_0(1+av),$$

where a is small, the wave throws off others of inferior amplitude and of a different period.

12. *Works and Memoirs on Waves.*—The literature is very extensive, so a few references only are given. The works of Lagrange, Laplace, Poisson, and Cauchy may be specially cited. Weber's *Wellenlehre*, and Scott Russell's papers, contain valuable experimental details. Theoretical papers of importance by Earnshaw, Kelland, Green, etc., treat of long waves. The collected works of Rankine, and particularly those of Stokes, deal in part with oscillatory waves. Stokes's "Reports on Hydrodynamics," in the *Trans. of the British Association*, are of great value in themselves, and contain numerous references. A very complete discussion of the mathematics of the subject is given by Professor Greenhill in the *American Journal of Mathematics*. Lord Rayleigh's *Sound*, and the memoirs of De St. Venant and Von Helmholtz, together with a remarkable series of papers by Sir W. Thomson, in recent volumes of the *Phil. Mag.* and *Proc. R. S. E.*, may fitly conclude the list. (P. G. T.)

WAVERTREE, a township of Lancashire, partly included within the parliamentary limits of Liverpool, 3 miles southeast of Liverpool Exchange. The churches are all modern. There is a small circle of monoliths on the southeast boundary of the township, called the Calder Stones. A cemetery of the Neolithic period was opened a few years ago. The town possesses roperies and a brewery. An extensive pumping station connected with the Liverpool water-works is in the vicinity. The population of the urban sanitary district (area 1838 acres) in 1871 was 7810, and in 1881 it was 11,097.

WAVE THEORY OF LIGHT.

Various forms of wave theory.

§ 1. A GENERAL statement of the principles of the undulatory theory, with elementary explanations has already been given under LIGHT, and in the article on ETHER the arguments which point to the existence of an all-pervading medium, susceptible in its various parts of an alternating change of state, have been traced by a master hand; but the subject is of such great importance, and is so intimately involved in recent opitical investigation and discovery, that a more detailed exposition of the theory, with application to the leading phenomena, was reserved for a special article. That the subject is one of difficulty may be at once admitted. Even in the theory of sound, as conveyed by aerial vibrations, where we are well acquainted with the nature and properties of the vehicle, the fundamental conceptions are not very easy to grasp, and their development makes heavy demands upon our mathematical resources. That the situation is not improved when the medium is hypothetical will be easily understood. For, although the evidence is overwhelming in favor of the conclusion that light is propagated as a vibration, we are almost entirely in the dark as to what it is that vibrates and the manner of vibration. This ignorance entails an appearance of vagueness even in those parts of the subject the treatment of which would not really be modified by the acquisition of a more precise knowledge, *e.g.*, the theory of the colors of thin plates, and of the resolving power of optical instruments. But in other parts of the subject, such as the explanation of the laws of double refraction and of the intensity of light reflected at the surface of a transparent medium, the vagueness is not merely one of language; and if we wish to reach definite results by the *a priori* road we must admit a hypothetical element, for which little justification can be given. The distinction here indicated should be borne clearly in mind. Many optical phenomena must necessarily agree with any kind of wave theory that can be proposed; others may agree or disagree with a particular form of it. In the latter case we may regard the special form as disproved, but the undulatory theory in the proper wider sense remains untouched.

Elastic solid theory.

Of such special forms of the wave theory the most famous is that which assimilates light to the transverse vibrations of an elastic solid. *Transverse* they must be in order to give room for the phenomena of polarization. This theory is a great help to the imagination, and allows of the deduction of definite results which are at any rate mechanically possible. An isotropic solid has in general two elastic properties—one relating to the recovery from an alteration of volume, and the other to the recovery from a state of shear, in which the strata are caused to slide over one another. It has been shown by Green that it would be necessary to suppose the luminiferous medium to be incompressible and thus the only admissible differences between one isotropic medium and another are those of *rigidity* and of *density*. Between these we are in the first instance free to choose. The slower propagation of light in glass than in air may be equally well explained by supposing the rigidity the same in both cases while the density is greater in glass, or by supposing that the density is the same in both cases while the rigidity is greater in air. Indeed there is nothing, so far, to exclude a more complicated condition of things, in which both the density and rigidity vary in passing from one medium to another, subject to the one condition only of making the ratio of velocities of propagation equal to the known refractive index between the media.

When we come to apply this theory to investigate the intensity of light reflected from (say) a glass surface, and to the diffraction of light by very small particles (as in the sky), we find that a reasonable agreement with the facts can be brought about only upon the supposition that the rigidity is the same (approximately, at any rate) in various media, and that the density alone varies. At the same time we have to suppose that the vibration is perpendicular to the plane of polarization.

Up to this point the accordance may be regarded as fairly satisfactory; but, when we extend the investigation to crystalline media in the hope of explaining the observed laws of double refraction, we find that the suppositions which would suit best here are inconsistent with the conclusions we have already arrived at. In the first place, and so long as we hold strictly to the analogy of an elastic solid, we can only explain double refraction as depending upon anisotropic rigidity, and this can hardly be reconciled with the view that the rigidity is the same in different isotropic media. And if we pass over this difficulty, and inquire what kind of double refraction a crystalline solid would admit of, we find no such correspondence with observation as would lead us to think that we are upon the right track. The theory of anisotropic solids, with its twenty-one elastic constants, seems to be too wide for optical double refraction, which is of a much simpler character.[1]

For these and other reasons, especially the awkwardness with which it lends itself to the explanation of dispersion, the elastic solid theory, valuable as a piece of purely dynamical reasoning, and probably not without mathematical analogy to the truth, can in optics be regarded only as an illustration.

Electro-magnetic theory.

In recent years a theory has been received with much favor in which light is regarded as an electromagnetic phenomenon. The dielectric medium is conceived to be subject to a rapidly periodic "electric displacement," the variations of which have the magnetic properties of an electric current. On the basis of purely electrical observations Maxwell calculated the velocity of propagation of such disturbances, and obtained a value not certainly distinguishable from the velocity of light. Such an agreement is very striking; and a further deduction from the theory, that the specific inductive capacity of a transparent medium is equal to the square of the refractive index, is supported to some extent by observation. The foundations of the electrical theory are not as yet quite cleared of more or less arbitrary hypothesis; but, when it becomes certain that a dielectric medium is susceptible of vibrations propagated with the velocity of light, there will be no hesitation in accepting the identity of such vibrations with those to which optical phenomena are due. In the meantime, and apart altogether from the question of its probable truth, the electromagnetic theory is very instructive, in showing us how careful we must be to avoid limiting our ideas too much as to the nature of the luminous vibrations.

§ 2. *Plane Waves of Simple Type.*

Whatever may be the character of the medium and of its vibration, the analytical expression for an infinite train of plane waves is

$$A \cos\left\{\frac{2\pi}{\lambda}(Vt-x)+a\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

in which λ represents the wave-length, and V the corresponding velocity of propagation. The coefficient A is called the amplitude, and its nature depends upon the medium and must therefore here be left an open question. The phase of the wave at a given time and place is represented by a. The expression retains the same value whatever integral number of wave-lengths be added to or subtracted from x. It is also periodic with respect to t, and the period is

$$\tau=\lambda/V \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

In experimenting upon sound we are able to determine independently τ, λ and V; but on account of its smallness the periodic time of luminous vibrations eludes altogether our means of observation, and is only known indirectly from λ and V by means of (2).

There is nothing arbitrary in the use of a circular function to represent the waves. As a general rule this is the only kind of wave which can be propagated without a change of form; and, even in the exceptional cases where the velocity is independent of wave-length, no generality is really lost by this procedure, because in accordance with Fourier's theorem any kind of periodic wave may be regarded as compounded of a series of such as (1), with wave-lengths in harmonical progression.

Composition of waves of like period.

A well-known characteristic of waves of type (1) is that any number of trains of various amplitudes and phases, but of the *same wave-length*, are equivalent to a single train of the same type. Thus

$$\Sigma A \cos\left\{\frac{2\pi}{\lambda}(Vt-x)+a\right\}$$

$$=\Sigma A \cos a . \cos\frac{2\pi}{\lambda}(Vt-x)-\Sigma A \sin a . \sin\frac{2\pi}{\lambda}(Vt-x)$$

$$=P \cos\left\{\frac{2\pi}{\lambda}(Vt-x)+\phi\right\} \quad . \quad . \quad . \quad . \quad . \quad (3),$$

where
$$P^2=(\Sigma A \cos a)^2+\Sigma(A \sin a)^2 \quad . \quad . \quad . \quad . \quad (4),$$

$$\tan\phi=\frac{\Sigma(A \sin a)}{\Sigma(A \cos a)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

An important particular case is that of two component trains only.

Two trains of waves.

$$A \cos\left\{\frac{2\pi}{\lambda}(Vt-x)+a\right\}+A' \cos\left\{\frac{2\pi}{\lambda}(Vt-x)+a'\right\}$$

$$=P \cos\left\{\frac{2\pi}{\lambda}(Vt-x)+\phi\right\},$$

where
$$P^2=A^2+A'^2+2AA' \cos(a-a') \quad . \quad . \quad . \quad . \quad (6).$$

The composition of vibrations of the same period is precisely analogous, as was pointed out by Fresnel, to the composition of forces, or indeed of any other two-dimensional vector quantities. The magnitude of the force corresponds to the amplitude of the vibration, and the inclination of the force corresponds to the phase. A group of forces, of equal intensity, represented by lines drawn from the centre to the angular points of a regular polygon, constitute a system in equilibrium. Consequently, a system of vibrations of equal amplitude and of phases symmetrically distributed round the period has a zero resultant.

According to the phase-relation, determined by $(a-a')$, the amplitude of the resultant may vary from $(A-A')$ to $(A+A')$. If A′ and A are equal, the minimum resultant is zero, showing that two equal trains of waves may neutralize one another. This happens when the phases are opposite, or differ by half a (complete) period, and the effect is usually spoken of as the *interference* of light. From a purely dynamical point of view the word is not very appropriate, the vibrations being simply *superposed* with as little interference as can be imagined.

§ 3. *Intensity.*

The intensity of light of given wave-length must depend upon the amplitude, but the precise nature of the relation is not at once apparent. We are not able to appreciate by simple inspection the relative intensities of two unequal lights; and, when we say, for example, that one candle is twice as bright as another, we mean that two of the latter burning independently would give us the same light as one of the former. This may be regarded as the definition; and then experiment may be appealed to to prove that the intensity of light from a given source varies inversely as the square of the distance. But our conviction of the truth of the law is perhaps founded quite as much upon the idea that something not liable to loss is radiated outwards, and is distributed in succession over the surfaces of spheres concentric with the source, whose areas are as the squares of the radii. The something can only be energy; and thus we are led to regard the rate at which energy is propagated across a given area parallel to the waves as the measure of intensity; and this is proportional, not to the first power, but to the *square* of the amplitude.

Photometry.

Practical photometry is usually founded upon the law of inverse squares (LIGHT, vol. xiv. pp. 587–88); and it should be remembered that the method involves essentially the use of a diffusing screen, the illumination of which, seen in a certain direction, is assumed to be independent of the precise direction in which the light falls upon it; for the distance of a candle, for example, cannot be altered without introducing at the same time a change in the apparent magnitude, and therefore in the incidents of some part at any rate of the light.

---

[1] See Stokes, "Report on Double Refraction," *Brit. Assoc. Report*, 1862, p. 253.

With this objection is connected another which is often of greater importance, the necessary enfeeblement of the light by the process of diffusion. And, if to maintain the brilliancy we substitute regular reflectors for diffusing screens, the method breaks down altogether by the apparent illumination becoming independent of the distance of the source of light.

The use of a revolving disk with transparent and opaque sectors in order to control the brightness, as proposed by Fox Talbot,[1] may often be recommended in scientific photometry, when a great loss of light is inadmissible. The law that, when the frequency of intermittence is sufficient to give a steady appearance, the brightness is proportional to the angular magnitude of the open sectors appears to be well established.

§ 4. *Resultant of a Large Number of Vibrations of Arbitrary Phase.*

We have seen that the resultant of two vibrations of equal amplitude is wholly dependent upon their phase-relation, and it is of interest to inquire what we are to expect from the composition of a large number (n) of equal vibrations of amplitude unity, and of arbitrary phases. The intensity of the resultant will of course depend upon the precise manner in which the phases are distributed, and may vary from n^2 to zero. But is there a definite intensity which becomes more and more probable as n is increased without limit?

The nature of the question here raised is well illustrated by the special case in which the possible phases are restricted to two *opposite* phases. We may then conveniently discard the idea of phase, and regard the amplitudes as at random *positive or negative*. If all the signs are the same, the intensity is n^2; if, on the other hand, there are as many positive as negative, the result is zero. But although the intensity may range from 0 to n^2, the smaller values are much more probable than the greater.

The simplest part of the problem relates to what is called in the theory of probabilities the "expectation" of intensity, that is the mean intensity to be expected after a great number of trials, in each of which the phases are taken at random. The chance that all the vibrations are positive is 2^{-n}, and thus the expectation of intensity corresponding to this contingency is $2^{-n}.n^2$. In like manner the expectation corresponding to the number of positive vibrations being $(n-1)$ is

$$2^{-n}.n.(n-2)^2,$$

and so on. The whole expectation of intensity is thus

$$\frac{1}{2^n}\left\{1.n^2 + n.(n-2)^2 + \frac{n(n-1)}{1\,.\,2}(n-4)^2 + \frac{n(n-1)(n-2)}{1\,.\,2\,.\,3}(n-6)^2 + \ldots\right\} \quad . \quad . \quad . \quad . \quad (1).$$

Now the sum of the $(n+1)$ terms of the series is simply n, as may be proved by comparison of coefficients of x^2 in the equivalent forms

$$(e^x + e^{-x})^n = 2^n(1 + \tfrac{1}{2}x^2 + \ldots)^n$$
$$= e^{nx} + ne^{(n-2)x} + \frac{n(n-1)}{1\,.\,2}e^{(n-4)x} + \ldots$$

The expectation of intensity is therefore n, and this whether n be great or small.

The same conclusion holds good when the phases are unrestricted. From (4) § 2, if $A=1$,

$$P^2 = n + 2\Sigma \cos(a_2 - a_1) \quad . \quad . \quad . \quad . \quad . \quad (2),$$

where under the sign of summation are to be included the cosines of the $\frac{1}{2}n(n-1)$ differences of phase. When the phases are arbitrary, this sum is as likely to be positive as negative, and thus the mean value of P^2 is n.

The reader must be on his guard here against a fallacy which has misled some high authorities. We have not proved that when n is large there is any tendency for a single combination to give the intensity equal to n, but the quite different proposition that in a large number of trials, in each of which the phases are rearranged arbitrarily, the *mean* intensity will tend more and more to the value n. It is true that even in a single combination there is no reason why any of the cosines in (2) should be positive rather than negative, and from this we may infer that when n is increased the sum of the terms tends to vanish in comparison with the number of terms. But, the number of terms being of the order n^2, we can infer nothing as to the value of the sum of the series in comparison with n.

Indeed it is not true that the intensity in a single combination approximates to n, when n is large. It can be proved[2] that the probability of a resultant intermediate in amplitude between r and $r+dr$ is

$$\frac{2}{n}e^{-r^2/n}r\,dr \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

The probability of an amplitude less than r is thus

$$\frac{2}{n}\int_0^r e^{-r^2/n}\,r\,dr = 1 - e^{-r^2/n} \quad . \quad . \quad . \quad . \quad . \quad (4).$$

or, which is the same thing, the probability of an amplitude greater than r is

$$e^{-r^2/n} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

The accompanying table gives the probabilities of intensities less than the fractions of n named in the first column. For example, the probability of intensity less than n is .6321.

.05	.0488	.80	.5506
.10	.0952	1.00	.6321
.20	.1813	1.50	.7768
.40	.3296	2.00	.8647
.60	.4512	3.00	.9502

It will be seen that however great n may be, there is a fair chance of considerable relative fluctuations of intensity in consecutive combinations.

The *mean* intensity, expressed by

$$\frac{2}{n}\int_0^\infty e^{-r^2/n}.r^2.dr,$$

is, as we have already seen, equal to n.

It is with this mean intensity only, that we are concerned in ordinary photometry. A source of light, such as a candle or even a soda flame, may be regarded as composed of a very large number of luminous centres disposed throughout a very sensible space; and, even though it be true that the intensity at a particular point of a screen illuminated by it and at a particular moment of time is a matter of chance, further processes of averaging must be gone through before anything is arrived at of which our senses could ordinarily take cognizance. In the smallest interval of time during which the eye could be impressed, there would be opportunity for any number of rearrangements of phase, due either to motions of the particles or to irregularities in their modes of vibration. And even if we supposed that each luminous centre was fixed, and emitted perfectly regular vibrations, the manner of composition and consequent intensity would vary rapidly from point to point of the screen, and in ordinary cases the mean illumination over the smallest appreciable area would correspond to a thorough averaging of the phase-relationships. In this way the idea of the intensity of a luminous source, independently of any questions of phase, is seen to be justified, and we may properly say that two candles are twice as bright as one.

§ 5. *Propagation of Waves in General.*

It has been shown under OPTICS that a system of rays, however many reflections or refractions they may have undergone, are always normal to a certain surface, or rather system of surfaces. From our present point of view these surfaces are to be regarded as wave-surfaces, that is, surfaces of constant phase. It is evident that, so long as the radius of curvature is very large in comparison with λ, each small part of a wave-surface propagates itself just as an infinite plane wave coincident with the tangent plane would do. If we start at time t with a given surface, the corresponding wave-surface at time $t+dt$ is to be found by prolonging every normal by the length Vdt, where V denotes the velocity of propagation at the place in question. If the medium be uniform, so that V is constant, the new surface is *parallel* to the old one, and this property is retained however many short intervals of time be considered in succession. A wave-surface thus propagates itself *normally*, and the corresponding parts of successive surfaces are those which lie upon the same normal. In this sense the normal may be regarded as a *ray*, but the idea must not be pushed to streams of light limited to pass through small apertures. The manner in which the phase is determined by the length of the ray, and the conditions under which energy may be regarded as travelling along a ray, will be better treated under the head of Huygens's principle, and the theory of shadows (§ 10).

---

[1] *Phil. Mag.*, v. p. 331, 1834.

[2] *Phil. Mag.*, Aug., 1880.

Fermat's principle.

From the law of propagation, according to which the wave-surfaces are always as far advanced as possible, it follows that the course of a ray, is that for which the time, represented by $\int V^{-1}ds$, is a minimum. This is Fermat's principle of least time. Since the refractive index (μ) varies as V^{-1}, we may take $\int \mu ds$ as the measure of the retardation between one wave-surface and another; and it is the same along whichever ray it may be measured.

Law of magnifying.

The principle that $\int \mu ds$ is a minimum along a ray lends itself readily to the investigation of optical laws. As an example, we will consider the very important theory of magnifying power. Let A_0, B_0 be two points upon a wave-surface before the light enters the object-glass of a telescope, A, B the corresponding points upon a wave-surface after emergence from the eye-piece, both surfaces being plane. The value of $\int \mu ds$ is the same along the ray A_0A as along B_0B; and, if from any cause B_0 be slightly retarded relatively to A_0, then B will be retarded to the same amount relatively to A. Suppose now that the retardation in question is due to a small rotation (θ) of the wave-surface A_0B_0 about an axis in its own plane perpendicular to AB. The retardation of B_0 relatively to A_0 is then $A_0B_0.\theta$; and in like manner, if ϕ be the corresponding rotation of AB, the retardation is $AB.\phi$. Since these retardations are the same, we have

$$\frac{\phi}{\theta} = \frac{A_0B_0}{AB},$$

or *the magnifying power is equal to the ratio of the widths of the stream of light before and after passing the telescope.*

Prisms.

The magnifying power is not necessarily the same in all directions. Consider the case of a prism arranged as for spectrum work. Passage through the prism does not alter the vertical width of the stream of light; hence there is no magnifying power in this direction. What happens in a horizontal direction depends upon circumstances. A single prism in the position of minimum deviation does not alter the horizontal width of the beam. The same is true of a sequence of any number of prisms each in the position of minimum deviation, or of the combination called by Thollon a couple, when the deviation is the least that can be obtained by rotating the couple as a *rigid system*, although a further diminution might be arrived at by violating this tie. In all these cases there is neither horizontal nor vertical magnification, and the instrument behaves as a telescope of power unity. If, however, a prism be so placed that the angle of emergence differs from the angle of incidence, the horizontal width of the beam undergoes a change. If the emergence be nearly grazing, there will be a high magnifying power in the horizontal direction; and, whatever may be the character of the system of prisms, the horizontal magnifying power is represented by the ratio of widths. Brewster suggested that, by combining two prisms with refracting edges at right angles, it would be possible to secure equal magnifying power in the two directions, and thus to imitate the action of an ordinary telescope.

Apparent brightness.

The theory of magnifying power is intimately connected with that of apparent brightness. By the use of a telescope in regarding a bright body, such, for example, as the moon, there is a concentration of light upon the pupil in proportion to the ratio of the area of the object-glass to that of the pupil.[1] But the apparent brightness remains unaltered, the apparent superficial magnitude of the object being changed in precisely the same proportion, in accordance with the law just established.

These fundamental propositions were proved a long while since by Coates and Smith; and a complete exposition of them, from the point of view of geometrical optics is to be found in Smith's treatise.[2]

§ 6. *Waves Approximately Plane or Spherical.*

A plane wave of course remains plane after reflection from a truly plane surface; but any irregularities in the surface impress themselves upon the wave. In the simplest case, that of perpendicular incidence, the irregularities are *doubled*, any depressed portion of the surface giving rise to a retardation in the wave front of twice its own amount. It is assumed that the lateral dimensions of the depressed or elevated parts are large multiples of the wave-length; otherwise the assimilation of the various parts to plane waves is not legitimate.

In like manner, if a plane wave passes perpendicularly through a parallel plate of refracting material, a small elevation t at any part of one of the surfaces introduces a retardation $(\mu - 1)t$ in the corresponding part of the wave-surface. An error in a glass surface is thus of only one-quarter of the importance of an equal error in a reflecting surface. Further, if a plate, otherwise true, be distorted by bending, the errors introduced at the two surfaces are approximately opposite, and neutralize one another.[3]

Symmetrical aberration.

In practical applications it is of importance to recognize the effects of a small departure of the wave-surface from its ideal plane or spherical form. Let the surface be referred to a system of rectangular co-ordinates, the axis of z being normal at the centre of the section of the beam, and the origin being the point of contact of the tangent plane. If, as happens in many cases, the surface be one of symmetry round OZ, the equation of the surface may be represented approximately by

$$z = r^2/2\rho + Ar^4 + \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

in which ρ is the radius of curvature, or focal length, and $r^2 = x^2 + y^2$. If the surface be truly spherical, $A = 1/8\rho^3$, and any deviation of A from this value indicates ordinary symmetrical spherical aberration.

Unsymmetrical aberration.

If, however, the surface be not symmetrical, we may have to encounter aberration of a lower order of small quantities, and therefore presumably of higher importance. By taking the axis of x and y coincident with the directions of principal curvature at O, we may write the equation of the surface

$$z = \frac{x^2}{2\rho} + \frac{y^2}{2\rho'} + \alpha x^3 + \beta x^2y + \gamma xy^2 + \delta y^3 \quad . \quad . \quad . \quad . \quad (2),$$

ρ, ρ' being the principal radii of curvature, or focal lengths. The most important example of unsymmetrical aberration is in the spectroscope, where (if the face of the prisms may be regarded as at any rate surfaces of revolution) the wave-surface may by suitable adjustments be rendered symmetrical with respect to the horizontal plane $y = 0$. This plane may then be regarded as primary, ρ being the primary focal length, at which distance the spectrum is formed. Under these circumstances β and δ may be omitted from (2), which thus takes the form

$$z = \frac{x^2}{2\rho} + \frac{y^2}{2\rho'} + \alpha x^3 + \gamma xy^2 \quad . \quad . \quad . \quad . \quad . \quad (3).$$

The constants α and γ in (3) may be interpreted in terms of the differential coefficients of the principal radii of curvature. By the usual formula the radius of curvature at the point x of the intersection of (3) with the plane $y = 0$ is approximately $\rho(1 - 6\alpha\rho x)$. Since $y = 0$ is a principal plane throughout, this radius of curvature is a principal radius of the surface; so that, denoting it by ρ, we have

$$\alpha = \frac{1}{6}\frac{d\rho^{-1}}{dx} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

Again, in the neighborhood of the origin, the approximate value of the product of the principal curvatures is

$$\frac{1}{\rho\rho'} + \frac{6\alpha x}{\rho'} + \frac{2\gamma x}{\rho}.$$

Thus

$$d\left(\frac{1}{\rho\rho'}\right) = -\frac{d\rho}{\rho^2\rho'} \quad \frac{d\rho'}{\rho'^2\rho} = \frac{6\alpha x}{\rho'} + \frac{2\gamma x}{\rho};$$

whence by (4)

$$\gamma = \tfrac{1}{2}\frac{d\rho'^{-1}}{dx} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

The equation of the normal at the point x, y, z is

$$\frac{\zeta - z}{-1} = \frac{\xi - x}{\rho^{-1}x + 3\alpha x^2 + \gamma y^2} = \frac{\eta - y}{\rho'^{-1}y + 2\gamma xy} \quad . \quad . \quad . \quad (6);$$

Primary focal line.

and its intersection with the plane $\zeta = \rho$ occurs at the point determined approximately by

$$\left.\begin{aligned} \xi &= -\rho(3\alpha x^2 + \gamma y^2) \\ \eta &= \frac{(\rho' - \rho)y}{\rho'} - 2\rho\gamma xy \end{aligned}\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7),$$

terms of the third order being omitted.

---

[1] It is here assumed that the object-glass is large enough to fill the whole of the pupil with light; also that the glasses are perfectly transparent, and that there is no loss of light by reflection. For theoretical purposes the latter requirement may be satisfied by supposing the transition between one optical medium and another to be gradual in all cases.

[2] Smith, *Compleat System of Optics*, Cambridge, 1738. The reader may be referred to a paper entitled "Notes, chiefly Historical, on some Fundamental Propositions in Optics" (*Phil. Mag.*, June, 1886), in which some account is given of Smith's work, and its relation to modern investigations.

[3] On this principle Grubb has explained the observation that the effects of bending stress are nearly as prejudicial in the case of thick object-glasses as in the case of thin ones.

According to geometrical optics, the thickness of the image of a luminous line at the primary focus is determined by the extreme value of ξ; and for good definition in the spectroscope it is necessary to reduce this thickness as much as possible. One way of attaining the desired result would be to narrow the aperture; but, as we shall see later, to narrow the horizontal aperture is really to throw away the peculiar advantage of large instruments. The same objection, however, does not apply to narrowing the *vertical* aperture; and in many spectroscopes a great improvement in definition may be thus secured. In general, it is necessary that both γ and α be small. Since the value of ξ does not depend on ρ', it would seem that in respect of definition there is no advantage in avoiding astigmatism.

Secondary focal line.

The width of the image when $\eta = 0$ (corresponding to $y = 0$) is $3\alpha\rho x^2$, and vanishes when $\alpha = 0$, *i.e.*, when there is no aberration for rays in the primary plane. In this case the image reduces to a linear arc. If further $\gamma = 0$, this arc becomes straight, and then the image at the primary focus is perfect to this order of approximation. As an example where $\alpha = 0$, the image of a luminous point, formed at an equal distance on the further side of a sloped equi-convex lens, may be mentioned.

At the secondary focus, $\zeta = \rho'$, and from (6)

$$\xi = x\frac{\rho - \rho'}{\rho}, \quad \eta = -2\rho'\gamma xy \quad . \quad . \quad . \quad . \quad . \quad . \quad (8).$$

If $\gamma = 0$, the secondary focal line is formed without aberration, but not otherwise. Both focal lines are well formed when parallel rays fall upon a plano-convex lens, sloped at about 30°, the curved side of the lens being turned towards the parallel rays.

§ 7. *Interference Fringes.*

We have seen (§ 2) that, when two trains of parallel waves of equal wave-length are superposed, the intensity of the resultant depends upon the phase-relation of the components; but it is necessarily the same at all points of the wave-front. It not unfrequently happens that the parallelism of the component trains is approximate only, and there then arises the phenomenon known as interference fringes. If the two directions of propagation be inclined on opposite sides to the axis of x at small angles α, the expressions for two components of equal amplitudes are

$$\cos\frac{2\pi}{\lambda}\left\{Vt - x\cos\alpha - y\sin\alpha\right\},$$

and

$$\cos\frac{2\pi}{\lambda}\left\{Vt - x\cos\alpha + y\sin\alpha\right\},$$

so that the resultant is expressed by

$$2\cos\frac{2\pi y\sin\alpha}{\lambda}\cos\frac{2\pi}{\lambda}(Vt - x\cos\alpha) \quad . \quad . \quad . \quad . \quad (1);$$

from which it appears that the vibrations advance parallel to the axis of x, unchanged in type, and with a uniform velocity $V/\cos\alpha$. Considered as depending on y, the vibration is a maximum when $y\sin\alpha$ is equal to 0, λ, 2λ, 3λ, etc., corresponding to the centres of the right bands, while for the intermediate values $\frac{1}{2}\lambda$, $\frac{3}{2}\lambda$, etc., there is no vibration. This is the interference of light proceeding from two similar homogeneous and very distant sources.

Fresnel's experiment.

In the form of experiment adopted by Fresnel the sources O_1, O_2[1] are situated at a finite distance D from the place of observation (LIGHT, vol. xiv. p. 611). If A be the point of the screen equidistant from O_1, O_2, and P a neighboring point, then approximately

$$O_1P - O_2P = \sqrt{\left\{D^2 + (u + \tfrac{1}{2}b)^2\right\}} - \sqrt{\left\{D^2 + (u - \tfrac{1}{2}b)^2\right\}} = ub/D,$$

where $O_1O_2 = b$, $AP = u$.

Thus, if λ be the wave-length, the places where the phases are accordant are given by

$$u = n\lambda D/b \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

n being an integer.

If the light were really homogeneous, the successive fringes would be similar to one another and unlimited in number; moreover there would be no place that could be picked out by inspection as the centre of the system. In practice λ varies, and the only place of complete accordance for all kinds of light is at A, where $u = 0$. Theoretically, there is no place of complete discordance for all kinds of light, and consequently no complete blackness. In consequence, however, of the fact that the range of sensitiveness of the eye is limited to less than an "octave," the centre of the first dark band (on either side) is sensibly black, even when white light is employed; but it should be carefully remarked that the existence of even one band is due to selection, and that the formation of several visible bands is favored by the capability of the retina to make chromatic distinctions within the visible range.

The number of perceptible bands increases *pari passu* with the approach of the light to homogeneity. For this purpose there are two methods that may be used.

Light originally homogeneous.

We may employ light, such as that from the soda flame, which possesses *ab initio* a high degree of homogeneity. If the range of wave-length included be $\frac{1}{50000}$, a corresponding number of interference fringes may be made visible. The above is the number obtained by Fizeau, and Michelson has recently gone as far as 200,000. The narrowness of the bright line of light seen in the spectroscope, and the possibility of a large number of Fresnel's bands, depend upon precisely the same conditions; the one is in truth as much an interference phenomenon as the other.

Spectroscopic method.

In the second method the original light may be highly composite, and homogeneity is brought about with the aid of a spectroscope. The analogy with the first method is closest if we use the spectroscope to give us a line of homogeneous light in simple substitution for the artificial flame. Or, following Foucault and Fizeau, we may allow the white light to pass, and subsequently analyze the mixture transmitted by a narrow slit in the screen upon which the interference bands are thrown. In the latter case we observe a channelled spectrum, with maxima of brightness corresponding to the wave-lengths $bu/(nD)$. In either case the number of bands observable is limited solely by the resolving power of the spectroscope (§ 13), and proves nothing with respect to the regularity, or otherwise, of the vibrations of the original light.

Achromatic bands.

The truth of this remark is strikingly illustrated by the possible formation, with white light, of a large number of achromatic bands. The unequal widths of the bands for the various colors, and consequent overlapping and obliteration, met with in the usual form of the experiment, depend upon the constancy of b (the mutual distance of the two sources) while λ varies. It is obvious that, if b were proportional to λ, the widths of the bands would be independent of λ, and that the various systems would fit together perfectly. To carry out the idea in its entirety, it would be necessary to use a diffraction spectrum as a source, and to duplicate this by Lloyd's method with a single reflector placed so that $b = 0$ when $\lambda = 0$. In practice a sufficiently good result could doubtless be obtained with a prismatic spectrum (especially if the red and violet were removed by absorbing agents) under the condition that $d(b/\lambda) = 0$ in the yellow-green. It is remarkable that, in spite of the achromatic character of the bands, their possible number is limited still by the resolving power of the instrument used to form the spectrum.

Airy's theory of the white centre.

If a system of Fresnel's bands be examined through a prism, the central white band undergoes an abnormal displacement, which has been supposed to be inconsistent with theory. The explanation has been shown by Airy[2] to depend upon the peculiar manner in which the white band is in general formed.

> "Any one of the kinds of homogeneous light composing the incident heterogeneous light will produce a series of bright and dark bars, unlimited in number as far as the mixture of light from the two pencils extends, and undistinguishable in quality. The consideration, therefore, of homogeneous light will never enable us to determine which is the point that the eye immediately turns to as the centre of the fringes. What then is the physical circumstance that determines the centre of the fringes?
>
> "The answer is very easy. For different colors the bars have different breadths. If then the bars of all colors coincide at one part of the mixture of light, they will not coincide at any other part; but at equal distances on both sides from that place of coincidence they will be equally far from a state of coincidence. If then we can find where the bars of all colors coincide, that point is the centre of the fringes.
>
> "It appears then that the centre of the fringes is *not* necessarily the point where the two pencils of light have described equal paths, but is determined by considerations of a perfectly different kind. . . . The distinction is important in this and in other experiments."

The effect in question depends upon the dispersive power of the prism. If v be the linear shifting due to the prism of the originally central band, v must be regarded as a function of λ. Measured from the original centre, the position of the n^{th} bar is now

---

[1] It is scarcely necessary to say that O_1, O_2 must not be distinct sources of light; otherwise there could be no fixed phase-relation and consequently no regular interference. In Fresnel's experiment O_1, O_2 are virtual images of one real source O, obtained by reflection in two mirrors. The mirrors may be replaced by a bi-prism. Or, as in Lloyd's arrangement, O_1 may be identical with O, and O_2 obtained by a grazing reflection from a single mirror.

[2] "Remarks on Mr. Potter's Experiment on Interference," *Phil., Mag.*, ii. p. 161, 1833.

$$v + n\lambda D/b.$$

The coincidence of the various bright bands occurs when this quantity is as independent as possible of λ, that is, when n is the nearest integer to

$$n = \frac{b}{D}\frac{dv}{d\lambda} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3);$$

or, as Airy expresses it in terms of the width of a band (h), $n = - dv/dh$.

The apparent displacement of the white band is thus not v simply, but

$$v - h\frac{dv}{dh} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

The signs of dv and dh being opposite, the abnormal diplacement is in addition to the normal effect of the prism. But, since dv/dh, or $dv/d\lambda$, is not constant, the achromatism of the white band is less perfect than when no prism is used.

If a grating were substituted for the prism, v would vary as h, and (4) would vanish, so that in all orders of spectra the white band would be seen undisplaced.

The theoretical error, dependent upon the dispersive power, involved in the method of determining the refractive index of a plate by means of the displacement of a system of interference fringes (LIGHT, vol. xiv. p. 611) has been discussed by Stokes.[1] In the absence of dispersion the retardation R due to the plate would be independent of λ, and therefore completely compensated at the point determined by $u = DR/b$; but when there is dispersion it is accompanied by a fictitious displacement of the fringes on the principle explained by Airy.

More recently the matter has engaged the attention of Cornu,[2] who thus formulates the general principle: "*Dans un système de franges d'interférences produites à l'aide d'une lumière hétérogène ayant un spectre continu, il existe toujours une frange achromatique qui joue le rôle de frange centrale et qui se trouve au point de champ où les radiations les plus intenses présentent une différence de phase maximum ou minimum.*"

In Fresnel's experiment, if the retardation of phase due to an interposed plate, or to any other cause, be F (λ), the whole relative retardation of the two pencils at the point u is

$$\phi = F(\lambda) + \frac{bu}{\lambda D} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5);$$

and the situation of the central, or achromatic, band is determined, not by $\phi = 0$, but by $d\phi/d\lambda = 0$, or

$$u = \lambda^2 DF(\lambda)/b \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6).$$

Limits to the width of the source of light.

In the theoretical statement we have supposed the source of light to be limited to a mathematical point, or to be extended only in the vertical direction (parallel to the bands). Such a vertical extension, while it increases illumination, has no prejudicial effect upon distinctness, the various systems due to different points of the luminous line being sensibly superposed. On the other hand, the horizontal dimension of the source must be confined within narrow limits, the condition obviously being that the displacement of the centre of the system incurred by using in succession the two edges only of the slit should be small in comparison with the width of an interference band.

Diffraction and Fresnel's bands.

Before quitting this subject it is proper to remark that Fresnel's bands are more influenced by diffraction than their discoverer supposed. On this account the fringes are often unequally broad and undergo fluctuations of brightness. A more precise calculation has been given by H. F. Weber[3] and by H. Struve,[4] but the matter is too complicated to be further considered here. The observations of Struve appear to agree well with the corrected theory.

§ 8. *Colors of Thin Plates.*

When plane waves of homogeneous light (λ) fall upon a parallel plate of index μ, the resultant reflected wave is made up of an infinite number of components, of which the most important are the first, reflected at the upper surface of the plate, and the second, transmitted at the upper surface, reflected at the under surface, and then transmitted at the upper surface. It is readily proved (LIGHT, vol. xiv. p. 611) that so far as it depends upon the distances to be travelled in the plate and in air the retardation (δ) of the second wave relatively to the first is given by

$$\delta = 2\mu t \cos \alpha' \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

where t denotes the thickness of the plate, and α' the angle of refraction corresponding to the first entrance. If we represent all the vibrations by complex quantities, from which finally the imaginary parts are to be rejected, the retardation δ may be expressed by the introduction of the factor $\varepsilon^{-i\kappa\delta}$, where $i = \sqrt{(-1)}$, and $\kappa = 2\pi/\lambda$.

Summation of partial waves.

At each reflection or refraction the amplitude of the incident wave must be supposed to be altered by a certain factor. When the light proceeds from the surrounding medium to the plate, the factor for reflection will be supposed to be b, and for refraction c; the corresponding quantities when the progress is from the plate to the surrounding medium will be denoted by e, f. Denoting the incident vibration by unity, we have then for the first component of the reflected wave b, for the second $cef\varepsilon^{-i\kappa\delta}$, for the third $ce^3f\varepsilon^{-2i\kappa\delta}$, and so on. Adding these together, and summing the geometric series, we find

$$b + \frac{cef\varepsilon^{-i\kappa\delta}}{1 - e^2\varepsilon^{-i\kappa\delta}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2).$$

In like manner for the wave transmitted through the plate we get

$$\frac{cf}{1 - e^2\varepsilon^{-i\kappa\delta}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3).$$

The quantities b, c, e, f are not independent. The simplest way to find the relations between them is to trace the consequences of supposing $\delta = 0$ in (2) and (3). For it is evident *a priori* that with a plate of vanishing thickness there must be a vanishing reflection, and a total transmission. Accordingly,

$$b + e = 0, \quad cf = 1 - e^2 \quad . \quad . \quad . \quad . \quad . \quad (4),$$

the first of which embodies Arago's law of the equality of reflections, as well as the famous "loss of half an undulation." Using these we find for the reflected vibration,

$$-\frac{e(1 - \varepsilon^{-i\kappa\delta})}{1 - e^2\varepsilon^{-i\kappa\delta}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

and for the transmitted vibration

$$\frac{1 - e^2}{1 - e^2\varepsilon^{-i\kappa\delta}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6).$$

Intensities.

The intensities of the reflected and transmitted lights are the squares of the moduli of these expressions. Thus

$$\text{Intensity of reflected light} = e^2 \frac{(1 - \cos\kappa\delta)^2 + \sin^2\kappa\delta}{(1 - e^2\cos\kappa\delta)^2 + e^4\sin^2\kappa\delta}$$

$$= \frac{4e^2 \sin^2(\frac{1}{2}\kappa\delta)}{1 - 2e^2\cos\kappa\delta + e^4} \quad . \quad . \quad . \quad . \quad (7);$$

$$\text{Intensity of transmitted light} = \frac{(1 - e^2)^2}{1 - 2e^2\cos\kappa\delta + e^4} \ldots (8),$$

the sum of the two expressions being unity.

Zero reflection at certain thicknesses.

According to (7) not only does the reflected light vanish completely when $\delta = 0$, but also whenever $\frac{1}{2}k\delta = n\pi$, n being an integer, that is, whenever $\delta = n\lambda$. When the first and third medium are the same, as we have here supposed, the central spot in the system of Newton's rings is *black* even though the original light contain a mixture of all wave lengths. The general explanation of the colors of Newton's rings is given under LIGHT, to which reference must be made. If the light reflected from a plate of any thickness be examined with a spectroscope of sufficient resolving power (§ 13), the spectrum will be traversed by dark bands, of which the centre corresponds to those wave lengths which the plate is incompetent to reflect. It is obvious that there is no limit to the fineness of the bands which may be thus impressed upon a spectrum, whatever may be the character of the original mixed light.

Principle of reversibility.

The relations between the factors b, c, e, f have been proved, independently of the theory of thin plates, in a general manner by Stokes,[5] who called to his aid the general mechanical principle of *reversibility*. If the motions constituting the reflected and refracted rays to which an incident ray gives rise be supposed to be reversed, they will reconstitute a reversed incident ray. This gives one relation; and another is obtained from the consideration that there is no ray in the second medium, such as would be generated by the operation alone of either the reversed reflected or refracted rays. Space does not allow of the reproduction of the argument at length, but a few words may perhaps give the reader an idea of

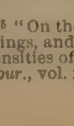


FIG. 1.

[4] *Wied. Ann.*, xv. p. 49.

[5] "On the Perfect Blackness of the Central Spot in Newton's Rings, and on the Verification of Fresnel's Formulæ for the Intensities of Reflected and Refracted Rays," *Camb. and Dub. Math. Jour.*, vol. iv. p. 1, 1849; reprint vol. ii. p. 89.

how the conclusions are arrived at. The incident ray (IA) being 1, the reflected (AR) and refracted (AF) rays are denoted by b and c. When b is reversed, it gives rise to a reflected ray b^2 along (AI) and a refracted ray bc along AG (say). When c is reversed, it gives rise to cf along AI, and ce along AG. Hence $bc + ce = 0$, $b^2 + cf = 1$, which agree with (4).

It is here assumed that there is no change of phase in the act of reflection or refraction, except such as can be represented by a change of sign. Professor Stokes has, however, pushed the application of his method to the case where changes of phase are admitted, and arrives at the conclusion that "the sum of the accelerations of phase at the two reflections is equal to the sum of the accelerations at the two refractions, and the accelerations of the two refractions are equal to each other." The accelerations are supposed to be so measured as to give like signs to c and f, and unlike to b and e. The same relations as before obtain between the factors b, c, e, f, expressing the ratios of amplitudes.[1]

Thin plate in contact with a perfect reflector.

When the third medium differs from the first, the theory of thin plates is more complicated, and need not here be discussed. One particular case, however, may be mentioned. When a thin transparent film is backed by a perfect reflector, no colors should be visible, all the light being ultimately reflected, whatever the wave length may be. The experiment may be tried with a thin layer of gelatin on a polished silver plate. In other cases where a different result is observed, the inference is that either the metal does not reflect perfectly, or else that the material of which the film is composed is not sufficiently transparent.

Colors of ancient glass.

Theory and observation alike show that the transmitted colors of a thin plate, *e.g.*, a soap film or a layer of air, are very inferior to those reflected. Specimens of ancient glass, which have undergone superficial decomposition, on the other hand, sometimes show transmitted colors of remarkable brilliancy. The probable explanation, suggested by Brewster, is that we have here to deal not merely with one, but with a series of thin plates of not very different thicknesses. It is evident that with such a series the transmitted colors would be much purer, and the reflected much brighter, than usual. If the thicknesses are strictly equal, certain wave-lengths must still be absolutely missing in the reflected light; while on the other hand a constancy of the interval between the plates will in general lead to a special preponderance of light of some other wave-length for which all the component parts as they ultimately emerge are in agreement as to phase.[2]

Colors of Newton's scale.

All that can be expected from a physical theory is the determination of the composition of the light reflected from or transmitted by a thin plate in terms of the composition of the incident light. The further question of the chromatic character of the mixtures thus obtained belongs rather to physiological optics, and cannot be answered without a complete knowledge of the chromatic relations of the spectral colors themselves. Experiments upon this subject have been made by various observers, and especially by Maxwell,[3] who has exhibited his results on a color diagram as used by Newton. A calculation of the colors of thin plates, based upon Maxwell's data, and accompanied by a drawing showing the curve representative of the entire series up to the fifth order, has recently been published;[4] and to this the reader who desires further information must be referred, with the remark that the true colors are not seen in the usual manner of operating with a plate of air enclosed between glass surfaces, on account of the contamination with white light reflected at the other surfaces of the glasses. This objection is avoided when a soap film is employed, to the manifest advantage of the darker colors, such as the red of the first order. The colors of Newton's scale are met with also in the light transmitted by a somewhat thin plate of doubly-refracting material, such as mica, the plane of analysis being perpendicular to that of primitive polarization.

The same series of colors occur also in other optical experiments, *e.g.*, at the centre of the illuminated area when light issuing from a point passes through a small round aperture in an otherwise opaque screen (§ 10).

Bands approximately achromatic.

The colors of which we have been speaking are those formed at nearly perpendicular incidence, so that the retardation (reckoned as a distance), viz., $2\mu t \cos\alpha'$, is sensibly independent of λ. This state of things may be greatly departed from when the thin plate is rarer than its surroundings, and the incidence is such that α' is nearly equal to 90°, for then, in consequence of the powerful dispersion, $\cos\alpha'$ may vary greatly as we pass from one color to another. Under these circumstances the series of colors entirely alters its character, and the bands (corresponding to a graduated thickness) may even lose their coloration, becoming sensibly black and white through many alternations.[5] The general explanation of this remarkable phenomenon was suggested by Newton, but it does not appear to have been followed out in accordance with the wave theory.

Let us suppose that plane waves of white light travelling in glass are incident at angle α upon a plate of air, which is bounded again on the other side by glass. If μ be the index of the *glass*, α' the angle of refraction, then $\sin\alpha' = \mu \sin\alpha$; and the retardation, expressed by the equivalent distance in air, is

$$2t \sec\alpha' - \mu . 2t \tan\alpha' \sin\alpha = 2t \cos\alpha' ;$$

and the retardation in *phase* is $2t \cos\alpha'/\lambda$, λ being as usual the wave-length in air.

The first thing to be noticed is that, when α approaches the critical angle, $\cos\alpha'$ becomes as small as we please, and that consequently the retardation corresponding to a given thickness is very much less than at perpendicular incidence. Hence the glass surfaces need not be so close as usual.

A second feature is the increased brilliancy of the light. According to (7) the intensity of the reflected light when at a maximum ($\sin\frac{1}{2}\kappa\delta = 1$) is $4e^2/(1 + e^2)^2$. At perpendicular incidence e is about $\frac{1}{5}$, and the intensity is somewhat small; but, as $\cos\alpha'$ approaches zero, e approaches unity (§ 26), and the brilliancy is much increased.

But the peculiarity which most demands attention is the lessened influence of a variation in λ upon the phase-retardation. A diminution of λ of itself increases the retardation of phase, but, since waves of shorter wave-length are more refrangible this effect may be more or less perfectly compensated by the greater obliquity, and consequent diminution in the value of $\cos\alpha'$. We will investigate the conditions under which the retardation of phase is stationary in spite of a variation of λ.

In order that $\lambda^{-1} \cos\alpha'$ may be stationary, we must have

$$\lambda \sin\alpha' d\alpha' + \cos\alpha' d\lambda = 0,$$

where (α being constant)

$$\cos\alpha' . d\alpha' = \sin\alpha \, d\mu .$$

Thus

$$\cot^2\alpha' = -\frac{\lambda}{\mu}\frac{d\mu}{d\lambda} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9),$$

giving α' when the relation between μ and λ is known.

According to Cauchy's formula, which represents the facts very well throughout most of the visible spectrum,

$$\mu = A + B\lambda^{-2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (10),$$

so that

$$\cot^2\alpha' = \frac{2B}{\lambda^2\mu} = \frac{2(\mu - A)}{\mu} \quad . \quad . \quad . \quad . \quad . \quad . \quad (11).$$

If we take, as for Chance's "extra-dense flint," $B = .984 \times 10^{-10}$, and, as for the soda lines, $\mu = 1.65$, $\lambda = 5.89 \times 10^{-5}$, we get

$$\alpha' = 79° \, 30'.$$

At this angle of refraction, and with this kind of glass, the retardation of phase is accordingly nearly independent of wave-length, and therefore the bands formed, as the thickness varies, are approximately achromatic. Perfect achromatism would be possible only under a law of dispersion,

---

[1] It would appear, however, that these laws cannot be properly applied to the calculation of reflection from a thin plate. This is sufficiently proved by the fact that the resultant expression for the intensity founded upon them does not vanish with the thickness. The truth is that the method of deducing the aggregate reflection from the consideration of the successive partial reflections and refractions is applicable only when the disturbance in the interior of the plate is fully represented by the transverse waves considered in the argument, whereas the occurrence of a change of phase is probably connected with the existence of additional superficial waves (§ 27). The existence of these superficial waves may be ignored when the reflected and refracted waves are to be considered only at distances from the surface exceeding a few wave lengths, but in the application to thin plates this limitation is violated. If indeed the method of calculating the aggregate reflection from a thin plate were sound when a change of phase occurs, we could still use the expressions (2) and (3), merely understanding by b, c, e, f, factors which may be complex, and the same formal relations (4) would still hold good. These do not agree with those found by Stokes by the method of reversion: and the discrepancy indicates that, when there are changes of phase, the action of a thin plate cannot be calculated in the usual way.

[2] The analytical investigations and formulæ given by Stokes for a pile of plates (*Proc. Roy. Soc.*, xi. p. 545, 1860) may be applied to this question, provided that we understand the quantities r, t, ϕ, ψ, etc., to be complex, so as to express the luminous displacement in phase as well as in amplitude, instead of real quantities relating merely to *intensities*.

$$\mu^2 = A' - B'\lambda^2.$$

If the source of light be distant and very small, the black bands are wonderfully fine and numerous. The experiment is best made (after Newton) with a right-angled prism, whose hypothenusal surface may be brought into approximate contact with a plate of black glass. The bands should be observed with a convex lens, of about 8 inches focus. If the eye be at twice this distance from the prism, and the lens be held midway between, the advantages are combined of a large field and of maximum distinctness.

Effect of a prism.

If Newton's rings are examined through a prism, some very remarkable phenomena are exhibited, described in his twenty-fourth observation.[1] "When the two object-glasses are laid upon one another, so as to make the rings of the colors appear, though with my naked eye I could not discern above eight or nine of those rings, yet by viewing them through a prism I could see a far greater multitude, insomuch that I could number more than forty. . . . . And I believe that the experiment may be improved to the discovery of far greater numbers. . . . . But it was on but one side of these rings, namely, that towards which the refraction was made, which by the refraction was rendered distinct, and the other side became more confused than when viewed with the naked eye. . . . .

"I have sometimes so laid one object-glass upon the other that to the naked eye they have all over seemed uniformly white, without the least appearance of any of the colored rings; and yet by viewing them through a prism great multitudes of those rings have discovered themselves."

Newton was evidently much struck with these "so odd circumstances;" and he explains the occurrence of the rings at unusual thicknesses as due to the dispersing power of the prism. The blue system being more refracted than the red, it is possible under certain conditions that the n^{th} blue ring may be so much displaced relatively to the corresponding red ring as *at one part of the circumference* to compensate for the different diameters. A white stripe may thus be formed in a situation where without the prism the mixture of colors would be complete, so far as could be judged by the eye.

The simplest case that can be considered is when the "thin plate" is bounded by plane surfaces inclined to one another at a small angle. By drawing back the prism (whose edge is parallel to the intersection of the above mentioned planes) it will always be possible so to adjust the effective dispersing power as to bring the n^{th} bars to coincidence for any two assigned colors, and therefore approximately for the entire spectrum. The formation of the achromatic band, or rather central black band, depends indeed upon the same principles as the fictitious shifting of the centre of a system of Fresnel's bands when viewed through a prism.

Condition of achromatism.

But neither Newton nor, as would appear, any of his successors has explained why the bands should be more numerous than usual, and under certain conditions sensibly achromatic for a large number of alternations. It is evident that, in the particular case of the wedge-shaped plate above specified, such a result would not occur. The width of the bands for any color would be proportional to λ, as well after the displacement by the prism as before; and the succession of colors formed in white light and the number of perceptible bands would be much as usual.

The peculiarity to be explained appears to depend upon the *curvature* of the surfaces bounding the plate. For simplicity suppose that the lower surface is plane ($y = 0$), and that the approximate equation of the upper surface is $y = a + bx^2$, a being thus the least distance between the plates. The black of the n^{th} order for wave-length λ occurs when

$$\tfrac{1}{2}n\lambda = a + bx^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12);$$

and thus the width (δx) at this place of the band is given by

$$\tfrac{1}{2}\lambda = 2bx\,\delta x \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13),$$

or

$$\delta x = \frac{\lambda}{4bx} = \frac{\lambda}{4\sqrt{b}\,.\,\sqrt{(\tfrac{1}{2}n\lambda - a)}} \quad . \quad . \quad . \quad . \quad . \quad (14).$$

If the glasses be in contact, as is usually supposed in the theory of Newton's rings, $a = 0$ and $\delta x \propto \lambda^{\frac{1}{2}}$, or the width of the band of the n^{th} order varies as the square root of the wave-length, instead of as the first power. Even in this case the overlapping and subsequent obliteration of the bands is greatly retarded by the use of the prism, but the full development of the phenomenon requires that a should be finite. Let us inquire what is the condition in order that the width of the band of the n^{th} order may be stationary, as λ varies. By (14) it is necessary that the variation of $\lambda^2/(\tfrac{1}{2}n\lambda - a)$ should vanish. Hence $a = \tfrac{1}{4}n\lambda$, so that the interval between the surfaces at the place where the n^{th} band is formed should be half due to curvature and half to imperfect contact at the place of closest approach. If this condition be satisfied, the achromatism of the n^{th} band, effected by the prism, carries with it the achromatism of a large number of neighboring bands, and thus gives rise to the remarkable effects described by Newton.

§ 9. *Newton's Diffusion Rings.*

In the fourth part of the second book of his *Optics* Newton investigates another series of rings, usually (though not very appropriately) known as the colors of thick plates. The fundamental experiment is as follows. At the centre of curvature of a concave looking-glass, quicksilvered behind, is placed an opaque card, perforated by a small hole through which sunlight is admitted. The main body of the light returns through the aperture; but a series of concentric rings are seen upon the card, the formation of which was proved by Newton to require the co-operation of the two surfaces of the mirror. Thus the diameters of the rings depend upon the thickness of the glass, and none are formed when the glass is replaced by a metallic speculum. The brilliancy of the rings depends upon imperfect polish of the anterior surface of the glass, and may be augmented by a coat of diluted milk, a device used by the Duc de Chaulnes. The rings may also be well observed without a screen in the manner recommended by Stokes. For this purpose all that is required is to place a *small* flame at the centre of curvature of the prepared glass, so as to coincide with its image. The rings are then seen surrounding the flame and occupying a definite position in space.

Stokes's principle.

The explanation of the rings, suggested by Young, and developed by Herschel, refers them to interference between one portion of light scattered or diffracted by a particle of dust, and then regularly refracted and reflected, and another portion first regularly refracted and reflected and then diffracted at emergence by the same particle. It has been shown by Stokes[2] that no regular interference is to be expected between portions of light diffracted by different particles of dust.

In the memoir of Stokes will be found a very complete discussion of the whole subject, and to this the reader must be referred who desires a fuller knowledge. Our limits will not allow us to do more than touch upon one or two points. The condition of fixity of the rings when observed in air, and of distinctness when a screen is used, is that the systems due to all parts of the diffusing surface should coincide; and it is fulfilled only when as in Newton's experiments, the source and screen are in the plane passing through the centre of curvature of the glass.

Plane mirror and lens.

As the simplest for actual calculation, we will consider a little further the case where the glass is plane and parallel, of thickness t and index μ, and is supplemented by a lens at whose focus the source of light is placed. This lens acts both as collimator and as object-glass, so that the combination of lens and plane mirror replaces the concave mirror of Newton's experiment. The retardation is calculated in the same way as for thin plates. In Fig. 2 the diffracting particle is situated at B, and we have to find the relative retardation of the two rays which emerge finally at inclination θ, the one diffracted at emergence following the path ABDBIE, and the other diffracted at entrance and following the path ABFGH. The retardation of the former from B to I is $2\mu t + \mathrm{BI}$, and of the latter from B to the equivalent place G is $2\mu\mathrm{BF}$. Now $\mathrm{FB} = t \sec\theta'$, θ', being the angle of refraction; $\mathrm{BI} = 2t \tan\theta' \sin\theta$; so that the relative retardation R is given by

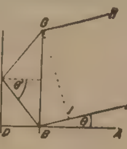

FIG. 2.

$$R = 2\mu t\left\{1 + \mu^{-1}\tan\theta'\sin\theta - \sec\theta'\right\} = 2\mu t(1 - \cos\theta').$$

If θ, θ' be small, we may take

$$R = 2t\theta^2/\mu \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

as sufficiently approximate.

The condition of distinctness is here satisfied, since R is the same for every ray emergent parallel to a given one. The rays of one parallel system are collected by the lens to a focus at a definite point in the neighborhood of the original source.

The formula (1) was discussed by Herschel, and shown to agree with Newton's measures. The law of formation of the rings follows immediately from the expression for the retardation, the radius of the ring of n^{th} order being proportional to n and to the square root of the wave-length.

§ 10. *Huygens's Principle. Theory of Shadows.*

The objection most frequently brought against the undulatory theory in its infancy was the difficulty of explaining in accordance with it the existence of shadows. Thanks to Fresnel and his followers, this department of optics is now precisely the one in which the theory has secured its greatest triumphs.

Huygen's principle.

The principle employed in these investigations is due to Huygens, and may be thus formulated. If round the origin of waves an ideal closed surface be drawn, the whole action of the waves in the region beyond may be regarded as due to the motion continually propagated across the various elements of this surface. The wave motion due to any element of the surface is called a *secondary* wave, and in estimating the total effect regard must be paid to the phases as well as the amplitudes of the components. It is usually convenient to choose as the surface of resolution a *wave-front, i.e.,* a surface at which the primary vibrations are in one phase.

Any obscurity that may hang over Huygens's principle is due mainly to the indefiniteness of thought and expression which we must be content to put up with if we wish to avoid pledging ourselves as to the character of the vibrations. In the application to sound, where we know what we are dealing with, the matter is simple enough in principle, although mathematical difficulties would often stand in the way of the calculation we might wish to make. The ideal surface of resolution may be there regarded as a flexible lamina; and we know that, if by forces locally applied every element of the lamina be made to move normally to itself exactly as the air at that place does, the external aerial motion is fully determined. By the principle of superposition the whole effect may be found by integration of the partial effects due to each element of the surface, the other elements remaining at rest.

Plane primary wave.

Elementary Huygens's zones.

We will now consider in detail the important case in which uniform plane waves are resolved at a surface coincident with a wave-front (OQ). We imagine the wave-front divided into elementary rings or zones, called Huygens's zones, by spheres described round P (the point at which the aggregate effect is to be estimated), the first sphere, touching the plane at O, with a radius equal to PO, and the succeeding spheres with radii increasing at each step by $\frac{1}{2}\lambda$. There are thus marked out a series of circles, whose radii x are given by $x^2+r^2=(r+\frac{1}{2}n\lambda)^2$, or ${}^2x=n\lambda r$ nearly; so that the rings are at first of nearly equal area. Now the effect upon P of each element of the plane is proportional to its area; but it depends also upon the distance from P, and possibly upon the inclination of the secondary ray to the direction of vibration and to the wave-front. These questions will be further considered in connection with the dynamical theory; but under all ordinary circumstances the result is independent of the precise answer that may be given. All that it is necessary to assume is that the effects of the successive zones gradually diminish, whether from the increasing obliquity of the secondary ray or because (on account of the limitation of the region of integration) the zones become at last more and more incomplete. The component vibrations at P due to the successive zones are thus nearly equal in amplitude and opposite in phase (the phase of each corresponding to that of the infinitesimal circle midway between the boundaries), and the series which we have to sum is one in which the terms are alternately opposite in sign, and while at first nearly constant in numerical magnitude, gradually diminish to zero. In such a series each term may be regarded as very nearly indeed destroyed by the halves of its immediate neighbors, and thus the sum of the whole series is represented by half the first term, which stands over uncompensated. The question is thus reduced to that of finding the effect of the first zone, or central circle, of which the area is $\pi\lambda r$.

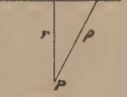

FIG. 3.

We have seen that the problem before us is independent of the law of the secondary wave as regards obliquity; but the result of the integration necessarily involves the law of the intensity and phase of a secondary wave as a function of r, the distance from the origin. And we may in fact, as was done by A. Smith,[1] determine the law of the secondary wave, by comparing the result of the integration with that obtained by supposing the primary wave to pass on to P without resolution.

Initial phase of secondary waves.

Now as to the phase of the secondary wave, it might appear natural to suppose that it starts from any point Q with the phase of the primary wave, so that on arrival at P it is retarded by the amount corresponding to QP. But a little consideration will prove that in that case the series of secondary waves could not reconstitute the primary wave. For the aggregate effect of the secondary waves is the half of that of the first Huygens zone, and it is the central element only of that zone for which the distance to be travelled is equal to r. Let us conceive the zone in question to be divided into infinitesimal rings of equal area. The effects due to each of these rings are equal in amplitude and of phase ranging uniformly over half a complete period. The phase of the resultant is midway between those of the extreme elements, that is to say, a quarter of a period behind that due to the element at the centre of the circle. It is accordingly necessary to suppose that the secondary waves start with a phase one-quarter of a period in advance of that of the primary wave at the surface of resolution.

Factor for secondary wave.

Further, it is evident that account must be taken of the variation of phase in estimating the magnitude of the effect at P of the first zone. The middle element alone contributes without deduction; the effect of every other must be found by introduction of a resolving factor, equal to $\cos\theta$, if θ represent the difference of phase between this element and the resultant. Accordingly, the amplitude of the resultant will be less than if all its components had the same phase, in the ratio

$$\int_{-\frac{1}{2}\pi}^{+\frac{1}{2}\pi}\cos\theta d\theta : \pi,$$

or $2:\pi$. Now $2 \text{ area } /\pi = 2\lambda r$; so that, in order to reconcile the amplitude of the primary wave (taken as unity) with the half effect of the first zone, the amplitude, at distance r, of the secondary wave emitted from the element of area dS must be taken to be

$$\frac{dS}{\lambda r} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1).$$

By this expression, in conjunction with the quarter-period acceleration of phase, the law of the secondary wave is determined.

That the amplitude of the secondary wave should vary as r^{-1} was to be expected from considerations respecting energy; but the occurrence of the factor λ^{-1}, and the acceleration of phase, have sometimes been regarded as mysterious. It may be well therefore to remember that precisely these laws apply to a secondary wave of sound, which can be investigated upon the strictest mechanical principles.

Analytical investigation.

The recomposition of the secondary waves may also be treated analytically. If the primary wave at O be $\cos \kappa at$, the effect of the secondary wave proceeding from the element dS at Q is

$$\frac{dS}{\lambda\rho}\cos\kappa(at-\rho+\tfrac{1}{4}\lambda)=-\frac{dS}{\lambda\rho}\sin\kappa(at-\rho).$$

If $dS=2\pi x dx$, we have for the whole effect

$$\frac{2\pi}{\lambda}\int_0^\infty \frac{\sin\kappa(at-\rho)x dx}{\rho},$$

or, since $x dx=\rho d\rho$, $\kappa=2\pi/\lambda$,

$$-\kappa\int_r^\infty \sin\kappa(at-\rho)d\rho=\Big[-\cos\kappa(at-\rho)\Big]_r^\infty.$$

In order to obtain the effect of the primary wave as retarded by traversing the distance r, viz., $\cos\kappa\,(at-r)$, it is necessary to suppose that the integrated term vanishes at the upper limit. And it is important to notice that without some further understanding the integral is really ambiguous. According to the assumed law of the secondary wave, the result must actually depend upon the precise radius of the outer boundary of the region of integration, supposed to be exactly circular. This case is, however, at most very special and exceptional. We may usually suppose that a large number of the outer rings are incomplete, so that the integrated term at the upper limit may properly be taken to vanish. If a formal proof be desired, it may be obtained by introducing into the integral a factor such as $e^{-h\rho}$, in which h is ultimately made to diminish without limit.

Primary wave curved.

When the primary wave is plane, the area of the first Huygens zone is $\pi\lambda r$, and, since the secondary waves vary as r^{-1}, the intensity is independent of r, as of course it should be. If, however, the primary wave be spherical, and of radius a at the wave-front of resolution, then we know that at a distance r further on the amplitude of the primary wave will be diminished in the ratio $a:(r+a)$. This may be regarded as a consequence of the altered area of the first Huygens zone. For, if x be its radius, we have

---

[1] *Camb. Math. Jour.*, iii. p. 46, 1843.

$$\{(r+\tfrac{1}{2}\lambda)^2-x^2\}+\sqrt{\{a^2-x^2\}}=r+a,$$

so that

$$x^2=\frac{\lambda ar}{a+r}\text{ nearly.}$$

Since the distance to be travelled by the secondary waves is still r, we see how the effect of the first zone, and therefore of the whole series is proportional to $a/(a+r)$. In like manner may be treated other cases, such as that of a primary wave-front of unequal principal curvatures.

Shadows.

The general explanation of the formation of shadows may also be conveniently based upon Huygens's zones. If the point under consideration be so far away from the geometrical shadow that a large number of the earlier zones are complete, then the illumination, determined sensibly by the first zone, is the same as if there were no obstruction at all. If, on the other hand, the point be well immersed in the geometrical shadow, the earlier zones are altogether missing, and, instead of a series of terms beginning with finite numerical magnitude and gradually diminishing to zero, we have now to deal with one of which the terms diminish to zero *at both ends*. The sum of such a series is very approximately zero, each term being neutralized by the halves of its immediate neighbors, which are of the opposite sign. The question of light or darkness then depends upon whether the series begins or ends abruptly. With few exceptions, abruptness can occur only in the presence of the first term, viz., when the secondary wave of least retardation is unobstructed, or when a *ray* passes through the point under consideration. According to the undulatory theory the light cannot be regarded strictly as travelling along a ray; but the existence of an unobstructed ray implies that the system of Huygens's zones can be commenced, and, if a large number of these zones are fully developed and do not terminate abruptly, the illumination is unaffected by the neighborhood of obstacles. Intermediate cases, in which a few zones only are formed belong especially to the province of diffraction.

Poisson's problem.

An interesting exception to the general rule that full brightness requires the existence of the first zone occurs when the obstacle assumes the form of a small circular disk parallel to the plane of the incident waves. In the earlier half of the 18th century[1] Delisle found that the centre of the circular shadow was occupied by a bright point of light, but the observation passed into oblivion until Poisson brought forward as an objection to Fresnel's theory that it required at the centre of a circular shadow a point as bright as if no obstacle were intervening. If we conceive the primary wave to be broken up at the plane of the disk, a system of Huygens's zones can be constructed which begin from the circumference; and the first zone external to the disk plays the part ordinarily taken by the centre of the entire system. The whole effect is the half of that of the first existing zone, and this is sensibly the same as if there were no obstruction.

Circular or annular aperture.

When light passes through a small circular or annular aperture, the illumination at any point along the axis depends upon the precise relation between the aperture and the distance from it at which the point is taken. If, as in the last paragraph, we imagine a system of zones to be drawn commencing from the inner circular boundary of the aperture, the question turns upon the manner in which the series terminates at the outer boundary. If the aperture be such as to fit exactly an integral number of zones, the aggregate effect may be regarded as the half of those due to the first and last zones. If the number of zones be even, the action of the first and last zones are antagonistic, and there is complete darkness at the point. If on the other hand the number of zones be odd, the effects conspire; and the illumination (proportional to the square of the amplitude) is four times as great as if there were no obstruction at all.

Soret's experiment.

The process of augmenting the resultant illumination at a particular point by stopping some of the secondary rays may be carried much further.[2] By the aid of photography it is easy to prepare a plate, transparent where the zones of odd order fall, and opaque where those of even order fall. Such a plate has the power of a condensing lens, and gives an illumination out of all proportion to what could be obtained without it. An even greater effect (fourfold) would be attained if it were possible to provide that the stoppage of the light from the alternate zones were replaced by a phase-reversal without loss of amplitude.

Degree of accuracy required.

In such experiments the narrowness of zones renders necessary a pretty close approximation to the geometrical conditions. Thus in the case of the circular disk, equidistant (r) from the source of light and from the screen upon which the shadow is observed, the width of the first exterior zone is given by

$$dx=\frac{\lambda(2r)}{4(2x)},$$

$2x$ being the diameter of the disk. If $2r=1000$ cm., $2x=1$ cm., $\lambda=6\times10^{-5}$ cm., then $dx=.0015$ cm. Hence, in order that this zone may be perfectly formed, there should be no error in the circumference of the order of .001 cm.[3] The experiment succeeds in a dark room of the length above mentioned, with a threepenny bit (supported by three threads) as obstacle, the origin of light being a small needle hole in a plate of tin, through which the sun's rays shine horizontally after reflection from an external mirror. In the absence of a heliostat it is more convenient to obtain a point of light with the aid of a lens of short focus.

Analytical expression.

The amplitude of the light at any point in the axis, when plane waves are incident perpendicularly upon an annular aperture, is as above,

$$\cos\kappa(at-r_1)-\cos\kappa(at-r_2)=2\sin\kappa at\,.\,\sin\kappa(r_1-r_2),$$

r_2, r_1 being the distances of the outer and inner boundaries from the point in question. It is scarcely necessary to remark that in all such cases the calculation applies in the first instance to homogeneous light, and that, in accordance with Fourier's theorem, each homogeneous component of a mixture may be treated separately. When the original light is white, the presence of some components and the absence of others will usually give rise to colored effects, variable with the precise circumstances of the case.

Uncertainty in the application of Huygens's principle.

Although what we have to say upon the subject is better postponed until we consider the dynamical theory, it is proper to point out at once that there is an element of assumption in the application of Huygens's principle to the calculation of the effects produced by opaque screens of limited extent. Properly applied, the principle could not fail; but, as may readily be proved in the case of sonorous waves, it is not in strictness sufficient to assume the expression for a secondary wave suitable when the primary wave is undisturbed, with mere limitation of the integration to the transparent parts of the screen. But, except perhaps in the case of very fine gratings, it is probable that the error thus caused is insignificant; for the incorrect estimation of the secondary waves will be limited to distances of a few wave-lengths only from the boundary of opaque and transparent parts.

§ 11. *Fraunhofer's Diffraction Phenomena.*

A very general problem in diffraction is the investigation of the distribution of light over a screen upon which impinge divergent or convergent spherical waves after passage through various diffracting apertures. When the waves are convergent and the recipient screen is placed so as to contain the centre of convergency—the image of the original radiant point, the calculation assumes a less complicated form. This class of phenomena was investigated by Fraunhofer (upon principles laid down by Fresnel), and are sometimes called after his name. We may conveniently commence with them on account of their simplicity and great importance in respect to the theory of optical instruments.

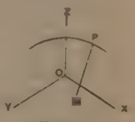

FIG. 4.

If f be the radius of the spherical wave at the place of resolution, where the vibration is represented by $\cos\kappa at$, then at any point M (Fig. 4) in the recipient screen the vibration due to an element dS of the wave-front is (§ 9)

$$\frac{dS}{\lambda\rho}\sin\kappa(at-\rho),$$

ρ being the distance between M and the element dS.

Taking co-ordinates in the plane of the screen with the centre of the wave as origin, let us represent M by ξ, η, and P (where dS is situated) by x, y, z. Then

$$\rho^2=(x-\xi)^2+(y-\eta)^2+z^2,\quad f^2=x^2+y^2+z^2;$$

so that

$$\rho^2=f^2-2x\xi-2y\eta+\xi^2+\eta^2.$$

In the applications with which we are concerned, ξ, η are very small quantities; and we may take

$$\rho=f\left\{1-\frac{x\xi+y\eta}{f^2}\right\}.$$

---

[1] Verdict, *Leçons d'Optique Physique*, 1 § 66.
[2] Soret, *Pogg. Ann.*, clvi. p. 99, 1875.

[3] It is easy to see that the radius of the bright spot is of the same order of magnitude.

At the same time dS may be identified with $dxdy$, and in the denominator ρ may be treated as constant and equal to f. Thus the expression for the vibration at M becomes

$$\frac{1}{\lambda f}\iint \sin\kappa\left\{at-f+\frac{x\xi+y\eta}{f}\right\}dxdy \quad . \quad . \quad . \quad (1);$$

and for the intensity, represented by the square of the amplitude,

Expression for intensity.

$$\mathrm{I}^2=\frac{1}{\lambda^2f^2}\left[\iint \sin\kappa\frac{x\xi+y\eta}{f}dxdy\right]^2 + \frac{1}{\lambda^2f^2}\left[\iint \cos\kappa\frac{x\xi+y\eta}{f}dxdy\right]^2 \quad . \quad . \quad . \quad . \quad (2)$$

This expression for the intensity becomes rigorously applicable when f is indefinitely great, so that ordinary optical aberration disappears. The incident waves are thus plane, and are limited to a plane aperture coincident with a wave-front. The integrals are then properly functions of the *direction* in which the light is to be estimated.

In the experiment under ordinary circumstances it makes no difference whether the collecting lens is in front of or behind the diffracting aperture. It is usually most convenient to employ a telescope focused upon the radiant point, and to place the diffracting apertures immediately in front of the object-glass. What is seen through the eye-piece in any case is the same as would be depicted upon a screen in the focal plane.

Before proceeding to special cases it may be well to call attention to some general properties of the solution expressed by (2).[1]

Theorems of Bridge.

If, when the aperture is given, the wave-length (proportional to κ^{-1}) varies, the composition of the integrals is unaltered, provided ξ and η are taken universely proportional to λ. A diminution of λ thus leads to a simple proportional shrinkage of the diffraction pattern, attended by an augmentation of brilliancy in proportion to λ^{-2}.

If the wave-length remains unchanged, similar effects are produced by an increase in the scale of the aperture. The linear dimension of the diffraction pattern is inversely as that of the aperture, and the brightness at corresponding points is as the *square* of the area of aperture.

If the aperture and wave-length increase in the same proportion, the size and shape of the diffraction pattern undergo no change.

Rectangular aperture.

We will now apply the integrals (2) to the case of a rectangular aperture of width a parallel to x and of width b parallel to y. The limits of integration for x may thus be taken to be $-\frac{1}{2}a$ and $+\frac{1}{2}a$, and for y to be $-\frac{1}{2}b$, $+\frac{1}{2}b$ We readily find (with substitution for κ of $2\pi/\lambda$)

$$\mathrm{I}^2=\frac{a^2b^2}{f^2\lambda^2}\cdot\frac{\sin^2\frac{\pi a\xi}{f\lambda}}{\frac{\pi^2a^2\xi^2}{f^2\lambda^2}}\cdot\frac{\sin^2\frac{\pi b\eta}{f\lambda}}{\frac{\pi^2b^2\eta^2}{f^2\lambda^2}} \quad . \quad . \quad . \quad . \quad . \quad (3),$$

as representing the distribution of light in the image of a mathematical point when the aperture is rectangular, as is often the case in spectroscopes.

The second and third factors of (3) being each of the form $\sin^2u/u^2$, we have to examine the character of this function. It vanishes when $u=m\pi$, m being any whole number other than zero. When $u=0$, it takes the value unity. The maxima occur when

$$u=\tan u, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4),$$

and then

$$\sin^2u/u^2=\cos^2u \quad . \quad . \quad . \quad . \quad . \quad . \quad (5).$$

To calculate the roots of (5) we may assume

$$u=(m+\tfrac{1}{2})\pi-y=\mathrm{U}-y,$$

where y is a positive quantity which is small when u is large. Substituting this, we find $\cot y=\mathrm{U}-y$, whence

$$y=\frac{1}{\mathrm{U}}\left(1+\frac{y}{\mathrm{U}}+\frac{y^2}{\mathrm{U}^2}+\ldots\right)-\frac{y^3}{3}-\frac{2y^5}{15}-\frac{17y^7}{315}.$$

This equation is to be solved by successive approximation. It will readily be found that

$$u=\mathrm{U}-y=\mathrm{U}-\mathrm{U}^{-1}-\frac{2}{3}\mathrm{U}^{-3}-\frac{13}{15}\mathrm{U}^{-5}-\frac{146}{105}\mathrm{U}^{-7}- . \quad (6).$$

In the first quadrant there is no root after zero, since $\tan u>u$, and in the second quadrant there is none because the signs of u and $\tan u$ are opposite. The first root after zero is thus in the third quadrant, corresponding to $m=1$. Even in this case the series converges sufficiently to give the value of the root with considerable accuracy, while for higher values of m it is all that could be desired. The actual values of u/π (calculated in another manner by Schwerd) are 1.4303, 2.4590, 3.4709, 4.4747, 5.4818, 6.4844, etc.

Since the maxima occur when $u=(m+\frac{1}{2})\pi$ nearly, the successive values are not very different from

$$\frac{4}{9\pi^2},\ \frac{4}{25\pi^2},\ \frac{4}{49\pi^2},\ \text{etc.}$$

Diffraction pattern.

The application of these results to (3) shows that the field is brightest at the centre $\xi=0$, $\eta=0$, viz., at the geometrical image. It is traversed by dark lines whose equations are

$$\xi=mf\lambda/a,\ \eta=mf\lambda/b.$$

Within the rectangle formed by pairs of consecutive dark lines, and not far from its centre, the brightness rises to a maximum; but these subsequent maxima are in all cases much inferior to the brightness at the centre of the entire pattern ($\xi=0, \eta=0$).

Total illumination.

By the principle of energy the illumination over the entire focal plane must be equal to that over the diffracting area; and thus, in accordance with the suppositions by which (3) was obtained, its value when integrated from $\xi=-\infty$ to $\xi=+\infty$, and from $\eta=-\infty$ to $\eta=+\infty$ should be equal to ab. This integration, employed originally by Kelland[2] to determine the absolute intensity of secondary wave, may be at once effected by means of the known formula

$$\int_{-\infty}^{+\infty}\frac{\sin^2u}{u^2}du=\int_{-\infty}^{+\infty}\frac{\sin u}{u}du=\pi.$$

It will be observed that, while the total intensity is proportional to ab, the intensity of the focal point is proportional to a^2b^2. If the aperture be increased, not only is the total brightness over the focal plane increased with it, but there is also a concentration of the diffraction pattern. The form of (3) shows immediately that, if a and b be altered, the co-ordinates of any characteristic point in the pattern vary as a^{-1} and b^{-1}.

Diffusion of images due to finite wave-length.

The contraction of the diffraction pattern with increase of aperture is of fundamental importance with reference to the resolving power of optical instruments. According to common optics, where images are absolute, the diffraction pattern is supposed to be infinitely small, and two radiant points, however near together, form separated images. This is tantamount to an assumption that λ is infinitely small. The actual finiteness of λ imposes a limit upon the separating or resolving power of an optical instrument.

This indefiniteness of images is sometimes said to be due to diffraction by the edge of the aperture, and proposals have even been made for curing it by causing the transition between the interrupted and transmitted parts of the primary wave to be less abrupt. Such a view of the matter is altogether misleading. What requires explanation is not the imperfection of actual images so much as the possibility of their being as good as we find them.

At the focal point ($\xi=0, \eta=0$) all the secondary waves agree in phase, and the intensity is easily expressed, whatever be the form of the aperture. From the general formula (2), if A be the *area* of aperture,

$$\mathrm{I}_0^2=\mathrm{A}^2/\lambda^2f^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7).$$

The formation of a sharp image of the radiant point requires that the illumination become insignificant when ξ, η attain small values, and this insignificance can only arise as a consequence of discrepancies of phase among the secondary waves from various parts of the aperture. So long as there is no sensible discrepancy of phase there can be no sensible diminution of brightness as compared with that to be found at the focal point itself. We may go further, and lay it down that there can be no considerable loss of brightness until the difference of phase of the waves proceeding from the nearest and furthest parts of the aperture amounts to $\frac{1}{4}\lambda$.

When the difference of phase amounts to λ, we may expect the resultant illumination to be very much reduced. In the particular case of a rectangular aperture the course of things can be readily followed, especially if we conceive f to be infinite. In the direction (suppose horizontal) for which $\eta=0$, $\xi/f=\sin\theta$, the phases of the secondary waves range over a complete period when $\sin\theta=\lambda/a$, and, since all parts of the horizontal aperture are equally effective, there is in this direction a complete compensation and consequent absence of illumination. When $\sin\theta=\frac{3}{2}\lambda/a$, the phases range one and a half periods, and there is revival of illumination. We may compare the brightness with that in the direction $\theta=0$. The phase of the resultant amplitude is the same as that due to the central secondary wave, and the discrepancies of phase among the components reduce the amplitude in the proportion

---

[1] Bridge, *Phil. Mag.*, Nov., 1858.

[2] *Ed. Trans.*, xv. 315.

$$\frac{1}{3\pi}\int_{\frac{3\pi}{2}}^{\frac{3\pi}{2}} \cos\phi\, d\phi : 1,$$

or $-\frac{2}{3\pi} : 1$; so that the brightness in this direction is $\frac{4}{9\pi^2}$ of the maximum at $\theta = 0$. In like manner we may find the illumination in any other direction, and it is obvious that it vanishes when $\sin\theta$ is any multiple of λ/a.

The reason of the augmentation of resolving power with aperture will now be evident. The larger the aperture the smaller are the angles through which it is necessary to deviate from the principal direction in order to bring in specified discrepancies of phase—the more concentrated is the image.

Luminous line.

In many cases the subject of examination is a luminous line of uniform intensity, the various points of which are to be treated as independent sources of light. If the image of the line be $\xi = 0$, the intensity at any point ξ, η of the diffraction pattern may be represented by

$$\int_{-\infty}^{+\infty} I^2 d\eta = \frac{a^2 b}{\lambda f} \frac{\sin^2 \frac{\pi a \xi}{\lambda f}}{\frac{\pi^2 a^2 \xi^2}{\lambda^2 f^2}} \quad . \quad . \quad . \quad . \quad (8),$$

the same law as obtains for a luminous point when horizontal directions are alone considered. The definition of a fine vertical line, and consequently the resolving power for contiguous vertical lines, is thus *independent of the vertical aperture of the instrument*, a law of great importance in the theory of the spectroscope.

The distribution of illumination in the image of a luminous line is shown by the curve ABC (Fig. 5), representing the value of the function $\sin^2 u/u^2$ from $u = 0$ to $u = 2\pi$. The part corresponding to negative values of u is similar, OA being a line of symmetry.

Double line.

Let us now consider the distribution of brightness in the image of a double line whose components are of equal strength, and at such an angular interval that the central line in the image of one coincides with the first zero of brightness in the image of the other. In Fig. 5 the curve of brightness for one component is ABC, and for the other OA′C′; and the curve representing half the combined brightnesses is E′BE. The brightness (corresponding to B) midway between the two central points AA′ is .8106 of the brightness at the central points themselves. We may consider this to be about the limit of closeness at which there could be any decided appearance of resolution, though doubtless an observer accustomed to his instrument would recognize the duplicity with certainty. The obliquity, corresponding to $u = \pi$, is such that the phases of the secondary waves range over a complete period, *i.e.*, such that the projection of the horizontal aperture upon this direction is one wave-length. We conclude that *a double line cannot be fairly resolved unless its components subtend an angle exceeding that subtended by the wave-length of light at a distance equal to the horizontal aperture.* This rule is convenient on account of its simplicity; and it is sufficiently accurate in view of the necessary uncertainty as to what exactly is meant by resolution.

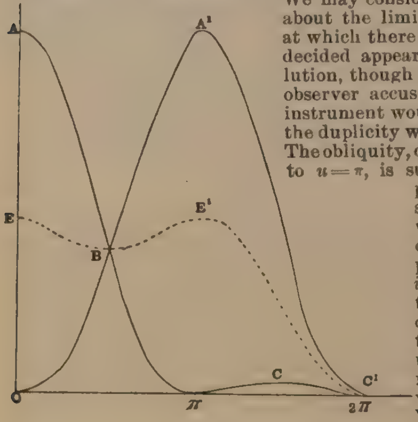

FIG. 5.

On the experimental confirmation of the theory of the resolving power of rectangular apertures, see OPTICS, vol. xvii. p. 830.

If the angular interval between the components of a double line be half as great again as that supposed in the figure, the brightness midway between is .1802 as against 1.0450 at the central lines of each image. Such a falling off in the middle must be more than sufficient for resolution. If the angle subtended by the components of a double line be twice that subtended by the wave-length at a distance equal to the horizontal aperture, the central bands are just clear of one another, and there is a line of absolute blackness in the middle of the combined images.

Central stops.

Since the limitation of the width of the central band in the image of a luminous line depends upon discrepancies of phase among the secondary waves, and since the discrepancy is greatest for the waves which come from the edges of the aperture, the question arises how far the operation of the central parts of the aperture is advantageous. If we imagine the aperture reduced to two equal narrow slits bordering its edges, compensation will evidently be complete when the projection on an oblique direction is equal to ½λ, instead of λ as for the complete aperture. By this procedure the width of the central band in the diffraction pattern is halved, and so far an advantage is attained. But, as will be evident, the bright bands bordering the central band are now not inferior to it in brightness; in fact, a band similar to the central band is reproduced an indefinite number of times, so long as there is no sensible discrepancy of phase in the secondary waves proceeding from the various parts of the *same* slit. Under these circumstances the narrowing of the band is paid for at a ruinous price, and the arrangement must be condemned altogether.

A more moderate suppression of the central parts is, however, sometimes advantageous. Theory and experiment alike prove that a double line, of which the components are equally strong, is better resolved when, for example, one-sixth of the horizontal aperture is blocked off by a central screen; or the rays quite at the centre may be allowed to pass, while others a little further removed are blocked off. Stops, each occupying one-eighth of the width, and with centres situated at the points of trisection, answer well the required purpose.

Total intensity proportional to aperture.

It has already been suggested that the principle of energy requires that the general expression for I^2 in (2) when integrated over the whole of the plane ξ, η should be equal to A, where A is the area of the aperture. A general analytical verification has been given by Stokes.[1] The expression for I^2 may be written in the form

$$I^2 = \frac{1}{\lambda^2 f^2}\iiiint \cos\frac{\kappa}{f}\left\{\xi(x'-x) + \eta(y'-y)\right\} dx\, dy\, dx'\, dy' \quad (9),$$

the integrations with respect to x', y' as well as those with respect to x, y being over the area of the aperture; and for the present purpose this is to be integrated again with respect to ξ, η, over the whole of the focal plane.

In changing the order of integration so as to take first that with respect to ξ, η, it is proper, in order to avoid ambiguity, to introduce under the integral sign the factor $e^{\pm\alpha\xi\pm\beta\eta}$, the + or — being chosen so as to make the elements of the integral vanish at infinity. After the operations have been performed, α and β are to be supposed to vanish. Thus $\iint I^2 d\xi d\eta =$ Limit of

$$\frac{1}{\lambda^2 f^2}\iiiint\!\!\iint e^{\mp\alpha\xi\mp\beta\eta} \cos\frac{\kappa}{f}\left\{\xi(x'-x) + \eta(y'-y)\right\}$$
$$dx\, dy\, dx'\, dy'\, d\xi\, d\eta.$$

Now $$\int_{-\infty}^{+\infty} e^{\mp\alpha\xi} \cos(h\xi - H)d\xi = \frac{2\alpha\cos H}{\alpha^2 + h^2};$$

and thus $\iint_{-\infty}^{+\infty} I^2 d\xi\, d\eta =$ Limit of

$$\frac{1}{\lambda^2 f^2}\iiiint \frac{4\alpha\beta\, dx\, dy\, dx'\, dy'}{\left\{\alpha^2 + \frac{\kappa^2(x'-x)^2}{f^2}\right\}\left\{\beta^2 + \frac{\kappa^2(y'-y)^2}{f^2}\right\}}.$$

Let $$\frac{\kappa(x'-x)}{f} = \alpha u, \quad dx' = \frac{f\alpha}{\kappa}du.$$

The limits for u are ultimately $-\infty$ and $+\infty$, and we have

$$\text{Limit} \int \frac{2\alpha\, dx'}{\left\{\alpha^2 + \frac{\kappa^2(x'-x)^2}{f^2}\right\}}$$
$$= \frac{2f}{\kappa}\int_{-\infty}^{+\infty} \frac{du}{1+u^2} = \frac{2f}{\kappa}\cdot\pi = f\lambda.$$

In like manner the integration for y' may be performed; and we find

$$\iint_{-\infty}^{+\infty} I^2 d\xi d\eta = \iint dx\, dy = A \quad . \quad . \quad . \quad (10).^{2}$$

We saw that I_0^2 (the intensity at the focal point) was equal to $A^2/\lambda^2 f^2$. If A′ be the area over which the intensity must be I_0^2 in order to give the actual total intensity in accordance with

---

[1] *Ed. Trans.*, xx. p. 317, 1853.

[2] It is easy to show that this conclusion is not disturbed by the introduction at every point of an arbitrary retardation ρ, a function of x, y. The terms $(\rho' - \rho)$ are then to be added under the cosine in (9); but they are ultimately without effect, since the only elements which contribute are those for which in the limit $x' = x$, $y' = y$, and therefore $\rho' = \rho$.

$$A'I_0'^2 = \iint_{-\infty}^{+\infty} I^2 d\xi\, d\eta,$$

the relation between A and A′ is $AA' = \lambda^2 f^2$. Since A′ is in some sense the area of the diffraction pattern, it may be considered to be a rough criterion of the definition, and we infer that the definition of a point depends principally upon the *area* of the aperture, and only in a very secondary degree upon the shape when the area is maintained constant.

§ 12. *Theory of Circular Aperture.*

We will now consider the important case where the form of the aperture is circular. Writing for brevity

$$\kappa\xi/f = p, \quad \kappa\eta/f = q, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

we have for the general expression (§ 11) of the intensity

$$\lambda^2 f^2 I^2 = S^2 + C^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (2),$$

where

$$S = \iint \sin(px + qy) dx\, dy, \quad . \quad . \quad . \quad . \quad (3),$$

$$C = \iint \cos(px + qy) dx\, dy, \quad . \quad . \quad . \quad . \quad (4).$$

When, as in the application to rectangular or circular apertures, the form is symmetrical with respect to the axes both of x and y, S=0, and C reduces to

$$C = \iint \cos px \cos qy\, dx\, dy, \quad . \quad . \quad . \quad . \quad (5).$$

In the case of the circular aperture the distribution of light is of course symmetrical with respect to the focal point $p = 0$, $q = 0$; and C is a function of p and q only through $\sqrt{(p^2 + q^2)}$. It is thus sufficient to determine the intensity along the axis of p. Putting $q = 0$, we get

$$C = \iint \cos px\, dx\, dy = 2\int_{-R}^{+R} \cos px \sqrt{(R^2 - x^2)} dx,$$

R being the radius of the aperture. This integral is the Bessel's function of order unity, defined by

$$J_1(z) = \frac{z}{\pi}\int_0^\pi \cos(z \cos\phi) \sin^2\phi\, d\phi \quad . \quad . \quad . \quad (6).$$

Thus, if $x = R\cos\phi$,

$$C = \pi R^2 \frac{2J_1(pR)}{pR} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7);$$

and the illumination at distance r from the focal point is

$$I^2 = \frac{\pi^2 R^4}{\lambda^2 f^2} \cdot \frac{4J_1^{\,2}\left(\frac{2\pi Rr}{f\lambda}\right)}{\left(\frac{2\pi Rr}{f\lambda}\right)^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (8).$$

The ascending series for $J_1(z)$, used by Airy[1] in his original investigation of the diffraction of a circular object-glass, and readily obtained from (6), is

$$J_1(z) = \frac{z}{2} - \frac{z^3}{2^2.4} + \frac{z^5}{2^2.4^2.6} - \frac{z^7}{2^2.4^2.6^2.8} + . \quad . \quad (9).$$

When z is great, we may employ the semi-convergent series

$$\begin{aligned} J_1(z) = & \sqrt{\left(\frac{2}{\pi z}\right)} \sin(z - \tfrac{1}{4}\pi)\left\{1 + \frac{3.5.1}{8.16}\left(\frac{1}{z}\right)^2 \right. \\ & \left. - \frac{3.5.7.9.1.3.5}{8.16.24.32}\left(\frac{1}{z}\right)^4 + \ldots\right\} \\ & + \sqrt{\left(\frac{2}{\pi z}\right)} \cos(z - \tfrac{1}{4}\pi)\left\{\frac{3}{8}\cdot\frac{1}{z} - \frac{3.5.7.1.3}{8.16.24}\left(\frac{1}{z}\right)^3 \right. \\ & \left. + \frac{3.5.7.9.11.1.3.5.7}{8.16.24.32.40}\left(\frac{1}{z}\right)^5 - \ldots\right\} \quad . \quad (10). \end{aligned}$$

A table of the values of $2z^{-1}J_1(z)$ has been given by Lommel,[2] to whom is due the first systematic application of Bessel's functions to the diffraction integrals.

The illumination vanishes in correspondence with the roots of the equation $J_1(z) = 0$. If these be called z_1, z_2, z_3, . . . the radii of the dark rings in the diffraction pattern are

$$\frac{f\lambda z_1}{2\pi R}, \frac{f\lambda z_2}{2\pi R}, \ldots$$

being thus *inversely* proportional to R.

The integrations may also be effected by means of polar co-ordinates, taking first the integration with respect to ϕ so as to obtain the result for an infinitely thin annular aperture. Thus, if

$$x = \rho\cos\phi, \quad y = \rho\sin\phi,$$

$$C = \iint \cos px\, dx\, dy = \int_0^R \int_0^{2\pi} \cos(p\rho \cos\theta)\, \rho d\rho\, d\theta.$$

Now by definition

$$J_0(z) = \frac{2}{\pi}\int_0^{\frac{1}{2}\pi} \cos(z\cos\theta)\, d\theta$$

$$= 1 - \frac{z^2}{2^2} + \frac{z^4}{2^2.4^2} - \frac{z^6}{2^2.4^2.6^2} + \ldots (11).$$

The value of C for an annular aperture of radius r and width dr is thus

$$dC = 2\pi J_0(p\rho)\, \rho d\rho, \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12).$$

For the complete circle,

$$\begin{aligned} C &= \frac{2\pi}{p^2}\int_0^{pR} J_0(z) z\, dz \\ &= \frac{2\pi}{p^2}\left\{\frac{p^2R^2}{2.} - \frac{p^4R^4}{2^2.4} + \frac{p^6R^6}{2^2.4^2.6} - \ldots\right\} \\ &= \pi R^2 \cdot \frac{2J_1(pR)}{pR}, \end{aligned}$$

as before.

In these expressions we are to replace p by $k\xi/f$, or rather, since the diffraction pattern is symmetrical, by kr/f, where r is the distance of any point in the focal plane from the centre of the system.

The roots of $J_0(z)$ after the first may be found from

$$\frac{z}{\pi} = i - .25 + \frac{.050661}{4i - 1} - \frac{.053041}{(4i - 1)^3} + \frac{.262051}{(4i - 1)^5} \quad . \quad . \quad (13),$$

and those of $J_1(z)$ from

$$\frac{z}{\pi} = i + .25 - \frac{.151982}{4i + 1} + \frac{.015399}{(4i + 1)^3} - \frac{.245835}{(4i + 1)^5} \quad . \quad . \quad (14),$$

formulæ derived by Stokes[3] from the descending series.[4] The following table gives the actual values:

i	$\frac{z}{\pi}$ for $J_0(z) = 0$	$\frac{z}{\pi}$ for $J_1(z) = 0$	i	$\frac{z}{\pi}$ for $J_0(z) = 0$	$\frac{z}{\pi}$ for $J_1(z) = 0$
1	.7655	1.2197	6	5.7522	6.2439
2	1.7571	2.2330	7	6.7519	7.2448
3	2.7546	3.2383	8	7.7516	8.2454
4	3.7534	4.2411	9	8.7514	9.2459
5	4.7527	5.2428	10	9.7513	10.2463

In both cases the image of a mathematical point is thus a symmetrical ring system. The greatest brightness is at the centre, where

$$dC = 2\pi\rho\, d\rho, \quad C = \pi R^2.$$

For a certain distance outwards this remains sensibly unimpaired, and then gradually diminishes to zero, as the secondary waves become discrepant in phase. The subsequent revivals of brightness forming the bright rings are necessarily of inferior brilliancy as compared with the central disk.

The first dark ring in the diffraction pattern of the complete circular aperture occurs when

$$r/f = 1.2197 \times \lambda/2R \quad . \quad . \quad . \quad . \quad . \quad (15).$$

We may compare this with the corresponding result for a rectangular aperture of width a,

$$\xi/f = \lambda/a;$$

and it appears that in consequence of the preponderance of the central parts, the compensation in the case of the circle does not set in at so small an obliquity as when the circle is replaced by a rectangular aperture, whose side is equal to the diameter of the circle.

Again, if we compare the complete circle with a narrow annular aperture of the same radius, we see that in the latter case the first dark ring occurs at a much smaller obliquity, viz.,

$$r/f = .7655 \times \lambda/2R.$$

Central stop.

It has been found by Herschel and others that the definition of a telescope is often improved by stopping off a part of the central area of the object-glass; but the advantage to be obtained in this way is in no case great, and anything like a reduction of the aperture to a narrow annulus is attended by a development of the external luminous rings sufficient to outweigh any improvement due to the diminished diameter of the central area.[5]

Maximum of brightness.

The maximum brightness and the places at which they occur are easily determined with the aid of certain properties of the Bessel's functions. It is known[6] that

---

[2] *Schlömilch*, xv. p. 166, 1870.

[3] *Camb. Trans.*, vol. ix., 1850.

[4] The descending series for $J_0(z)$ appears to have been first given by Sir W. Hamilton in a memoir on "Fluctuating Functions," *Roy. Irish Trans.*, 1840.

[5] Airy, *loc. cit.* "Thus the magnitude of the central spot is diminished, and the brightness of the rings increased, by covering the central parts of the object-glass."

[6] Todhunter's *Laplace's Functions*, ch. xxxi.

$$J_0'(z) = -J_1(z), \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (16);$$

$$J_2(z) = \frac{1}{z}J_1(z) - J_1'(z) \quad . \quad . \quad . \quad . \quad . \quad . \quad (17);$$

$$J_0(z) + J_2(z) = \frac{2}{z}J_1(z) \quad . \quad . \quad . \quad . \quad . \quad . \quad (18).$$

The maxima of C occur when

$$\frac{d}{dz}\left(\frac{J_1(z)}{z}\right) = \frac{J_1'(z)}{z} - \frac{J_1(z)}{z^2} = 0;$$

or by (17) when $J_2(z) = 0$. When z has one of the values thus determined,

$$\frac{2}{z}J_1(z) = J_0(z).$$

The accompanying table is given by Lommel,[1] in which the first column gives the roots of $J_2(z) = 0$, and the second and third columns the corresponding values of the functions specified. It appears that the maximum brightness in the first ring is only about $\frac{1}{57}$ of the brightness at the centre.

z	$2z^{-1}J_1(z)$	$4z^{-2}J_1{}^2(z)$
.000000	+1.000000	1.000000
5.135630	− .132279	.017498
8.417236	+ .064482	.004158
11.619857	− .040008	.001601
14.795938	+ .027919	.000779
17.959820	− .020905	.000437

Integrated intensity.

We will now investigate the total illumination distributed over the area of the circle of radius r. We have

$$I^2 = \frac{\pi^2R^4}{\lambda^2f^2} \cdot \frac{4J_1{}^2(z)}{z^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (19),$$

where

$$z = 2\pi Rr/\lambda f \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (20).$$

Thus

$$2\pi\int I^2rdr = \frac{\lambda^2f^2}{2\pi R^2}\int I^2zdz = \pi R^2 \,.\, 2\int z^{-1}J_1{}^2(z)\,dz.$$

Now by (17), (18)

$$z^{-1}J_1(z) = J_0(z) - J_1'(z);$$

so that

$$z^{-1}J_1{}^2(z) = -\tfrac{1}{2}\frac{d}{dz}J_0{}^2(z) - \tfrac{1}{2}\frac{d}{dz}J_1{}^2(z),$$

and

$$2\int_0^z z^{-1}J_1{}^2(z)dz = 1 - J_0{}^2(z) - J_1{}^2(z) \quad . \quad (21).$$

If r, or z, be infinite, $J_0(z)$, $J_1(z)$ vanish, and the whole illumination is expressed by πR^2, in accordance with the general principle. In any case the proportion of the whole illumination to be found outside the circle of radius r is given by

$$J_0{}^2(z) + J_1{}^2(z).$$

For the dark rings $J_1(z) = 0$; so that the fraction of illumination outside any dark ring is simply $J_0{}^2(z)$. Thus for the first, second, third, and fourth dark rings we get respectively .161, .090, .062, .047, showing that more than $\frac{9}{10}$ths of the whole light is concentrated within the area of the second dark ring.[2]

When z is great, the descending series (10) gives

$$\frac{2J_1(z)}{z} = \frac{2}{z}\sqrt{\left(\frac{2}{\pi z}\right)}\sin\,(z - \tfrac{1}{4}\pi) \quad . \quad . \quad . \quad . \quad (22);$$

so that the places of maxima and mimima occur at equal intervals.

The mean brightness varies as z^{-3} (or as r^{-3}), and the integral found by multiplying it by zdz and integrating between 0 and ∞ converges.

It may be instructive to contrast this with the case of an infinitely narrow annular aperture, where the brightness is proportional to $J_0{}^2(z)$. When z is great,

$$J_0(z) = \sqrt{\left(\frac{2}{\pi z}\right)}\cos\,(z - \tfrac{1}{4}\pi).$$

The mean brightness varies as z^{-1}; and the integral $\int_0^x J_0{}^2(z)\,z\,dz$ is not convergent.

Resolving power of telescopes.

The efficiency of a telescope is of course intimately connected with the size of the disk by which it represents a mathematical point. The resolving power upon double stars of telescopes of various apertures has been investigated by Dawes and others (OPTICS, vol. xvii. p. 830), with results that agree fairly well with theory.

Luminous line.

If we integrate the expression (8) for I^2 with respect to η, we shall obtain a result applicable to a linear luminous source of which the various parts are supposed to act independently.

From (19), (20)

$$d\xi\int_{-\infty}^{+\infty} I^2d\eta \quad \frac{2\pi^2R^4}{\lambda^2f^2}d\xi\int_0^{\infty} 4z^{-2}J_1{}^2(z)d\eta$$

$$= 2R^2\,d\xi\int\frac{J_1{}^2(z)\,dz}{z\,.\,\eta},\ \text{since}\ \eta^2 = r^2 - \xi^2.$$

If we write $\qquad \zeta = 2\pi R\xi/\lambda f \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (23),$

we get
$$d\xi\,.\int_{-\infty}^{+\infty} I^2d\eta = 2R^2d\zeta\,.\int_{\zeta}^{\infty}\frac{J_1{}^2(z)dz}{z\sqrt{(z^2-\zeta^2)}} \quad . \quad (24).$$

This integral has been investigated by H. Struve,[3] who, calling to his aid various properties of Bessel's functions, shows that

$$\int_{\zeta}^{\infty}\frac{J_1{}^2(z)dz}{z\sqrt{(z^2-\zeta^2)}} = \frac{2}{\pi}\frac{1}{\zeta}\int_0^{\frac{1}{2}\pi}\sin\,(2\zeta\sin\beta)\cos^2\beta d\beta \quad (25),$$

of which the right-hand member is readily expanded in powers of ζ. By means of (24) we may verify that

$$\int_{-\infty}^{+\infty}d\xi\int_{-\infty}^{+\infty}I^2d\eta = \pi R^2.$$

Contrary to what would naturally be expected, the subject is more easily treated without using the results of the integration with respect to x and y, by taking first of all, as in the investigation of Stokes (§ 11), the integration with respect to η. Thus

$$\lambda^2f^2\int_{-\infty}^{+\infty}I^2d\eta = \text{Limit of}$$

$$\int\!\!\int\!\!\int\!\!\int\!\!\int e^{\mp\beta\eta}\cos\frac{\kappa}{f}\Big\{\xi(x'-x)$$

$$+\eta(y'-y)\Big\}\,dx\,dy\,dx'\,dy'\,d\eta \quad (26);$$

and
$$\int_{-\infty}^{+\infty}e^{\mp\beta\eta}\cos\frac{\kappa}{f}\Big\{\xi(x'-x)+\eta(y'-y)\Big\}\,d\eta$$

$$= \frac{2\beta\cos\frac{\kappa\xi}{f}(x'-x)}{\beta^2+\frac{\kappa^2(y'-y)^2}{f^2}} \quad . \quad . \quad . \quad . \quad . \quad (27).$$

We have now to consider

$$\int\!\!\int\frac{2\beta\,dy\,dy'}{\beta^2+\kappa^2(y'-y)^2/f^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (28).$$

In the integration with respect to y' every element vanishes in the limit ($\beta = 0$), unless $y^1 = y$. If the range of integration for y' includes the value y, then

$$\text{Limit}\int\frac{2\beta\,dy'}{\beta^2+\kappa^2(y'-y)^2/f^2} = f\lambda;$$

otherwise it vanishes.

The limit of (28) may thus be denoted by $\lambda\,f\,Y$, where Y is the *common part* of the ranges of integration for y' and y corresponding to any values of x' and x. Hence

$$\int_{-\infty}^{+\infty}I^2d\eta = \lambda^{-1}f^{-1}\int\!\!\int Y\cos\frac{\kappa\xi}{f}(x'-x)\,dx\,dx'$$

$$= \lambda^{-1}f^{-1}\int\!\!\int Y\cos\frac{\kappa\xi x}{f}\cos\frac{\kappa\xi x'}{f}\,dx\,dx' \quad . \quad . \quad (29),$$

if, as for the present purpose, the aperture is symmetrical with respect to the axis of y.

In the application to the circle we may write

$$\int_{-\infty}^{+\infty}I^2d\eta = 4\lambda^{-1}f^{-1}\int_0^R\int_0^R Y\cos\frac{\kappa\xi x}{f}\cos\frac{\kappa\xi x'}{f}\,dx\,dx',$$

where Y is the smaller of the two quantities

$$2\sqrt{(R^2-x'^2)},\ 2\sqrt{(R^2-x^2)},$$

i.e., corresponds to the *larger* of the two abscissæ x', x. If we take $Y = 2\sqrt{(R^2-x^2)}$, and limit the integration to those values of x' which are less than x, we should obtain exactly the half of the required result. Thus

$$\int_{-\infty}^{+\infty}I^2d\eta = 16\lambda^{-1}f^{-1}\int_0^R\int_0^x\sqrt{(R^2-x^2)}\cos\frac{\kappa\xi x}{f}\cos\frac{\kappa\xi x'}{f}\,dx\,dx'$$

$$= \frac{4}{\pi\xi}\int_0^R\sqrt{(R^2-x^2)}\sin\frac{2\kappa\xi x}{f}dx$$

$$= \frac{4R^2}{\pi\xi}\int_0^{\frac{1}{2}\pi}\cos^2\beta\,\sin\frac{2\kappa\xi R\sin\beta}{f}d\beta$$

Hence, writing as before $\zeta = \frac{2\pi R\xi}{\lambda f}$, we get

---

[1] *loc. cit.*

[2] *Phil. Mag.*, March, 1881.

[3] *Wied. Ann.*, xvii. 1008, 1882.

$$d\xi\int_{-\infty}^{+\infty}\mathrm{I}^2 d\eta=\frac{4\mathrm{R}^2}{\pi}\cdot\frac{d\xi}{\xi}\cdot\int_0^{\frac{1}{2}\pi}\cos^2\beta\sin(2\zeta\beta)\,d\beta\ . \quad (30),$$

in which we may replace $d\xi/\xi$ by $d\zeta/\zeta$, in agreement with the result obtained by Struve.

The integral in (30) may be written in another form. We have

$$\int\zeta\sin(2\zeta\beta)\cos^2\beta\,d\beta$$

$$=-\tfrac{1}{2}\cos\beta\cos(2\zeta\sin\beta)-\tfrac{1}{2}\int\cos(2\zeta\sin\beta)\sin\beta\,d\beta\,;$$

and thus

$$\int_0^{\frac{1}{2}\pi}\zeta\sin(2\zeta\beta)\cos^2\beta\,d\beta=\tfrac{1}{2}\int_0^{\frac{1}{2}\pi}\Big\{1-\cos(2\zeta\sin\beta)\Big\}\sin\beta\,d\beta.$$

$$=\int_0^{\frac{1}{2}\pi}\sin^2(\zeta\sin\beta)\sin\beta d\beta\quad .\ .\ .\ .\quad (31).$$

The integral is thus expressible by means of the function K_1,[1] and we have

$$d\xi\int_{-\infty}^{+\infty}\mathrm{I}^2 d\eta=\tfrac{1}{2}\mathrm{R}^2\zeta^{-3}d\zeta\,\mathrm{K}_1(2\zeta)\quad .\ .\quad (32).$$

The ascending series for $\mathrm{K}_1(z)$ is

$$\mathrm{K}_1(z)=\frac{2}{\pi}\left\{\frac{z^3}{1^2.3}-\frac{z^5}{1^2.3^2.5}+\frac{z^7}{1^2.3^2.5^2.7}-\ldots\right\}\quad (33);$$

and this is always convergent. The descending semi-convergent series is

$$\mathrm{K}_1(z)=\frac{2}{\pi}\left\{z+z^{-1}-3.z^{-3}+1^2.3^2.5.z^{-5}-1^2.3^2.5^2.7.z^{-7}+\ldots\right\}$$

$$-\sqrt{\left(\frac{2z}{\pi}\right)}.\cos(z-\tfrac{1}{4}\pi)\left\{1-\frac{(1^2-4)(3^2-4)}{1.2.(8z)^2}+\ldots.\right\}$$

$$-\sqrt{\left(\frac{2z}{\pi}\right)}.\sin(z-\tfrac{1}{4}\pi)\left\{\frac{1^2-4}{1.8z}-\frac{(1^2-4)(3^2-4)(5^2-4)}{1.2.3.(8z)^3}+\ldots\right\}\quad (34),$$

the series within braces being the same as those which occur in the expression of the function $\mathrm{J}_1(z)$.

When ζ (or ξ) is very great,

$$d\xi\int_{-\infty}^{+\infty}\mathrm{I}^2 d\eta=\frac{2\mathrm{R}^2}{\pi}\zeta^{-2}d\zeta,$$

so that the intensity of the image of a luminous line is ultimately inversely as the square of the distance from the central axis, or geometrical image.

As is evident from its composition, the intensity remains finite for all values of ζ; it is, however, subject to fluctuations presenting maxima and minima, which have been calculated by Ch. André,[2] using apparently the method of quadratures.

	ζ	Intensity.
On the axis itself	0.00	1
First minimum	3.55	$\frac{1}{34}$
First maximum	4.65	$\frac{1}{24}$
Second minimum	6.80	$\frac{1}{115}$
Second maximum	8.00	$\frac{1}{80}$
Third minimum	9.60	$\frac{1}{419}$
Third maximum	11.00	$\frac{1}{208}$
Fourth minimum	13.20	$\frac{1}{10000}$

The results are also exhibited by M. André in the form of a curve, of which Fig. 6 is a copy.

Double line.

It will be seen that the distribution of brightness does not differ greatly from that due to a rectangular aperture whose width (perpendicular to the luminous line) is equal to the diameter of the circular aperture. It will be instructive to examine the image of a double line, whose components present an interval corresponding to $\zeta=\pi$, and to compare the result with that already found for a rectangular aperture (§ 11). We may consider the brightness at distance ζ proportional to

$$\mathrm{L}(\zeta)=\frac{1}{1^2.3}-\frac{2^2\zeta^2}{1^2.3^2.5}+\frac{2^4\zeta^4}{1^2.3^2.5^2.7}-\quad .\ .\quad (35).$$

In the compound image the illumination at the geometrical focus of one of the luminous lines is represented by

$$\mathrm{L}(0)+\mathrm{L}(\pi)\,;$$

and the illumination midway between the geometrical images of the two lines is

$$2\mathrm{L}(\tfrac{1}{2}\pi).$$

We find by actual calculation from the series, $\mathrm{L}(\pi)=.0164$, $\mathrm{L}(\tfrac{1}{2}\pi)=.1671$, $\mathrm{L}(0)=.3333$, so that

$$\mathrm{L}(0)+\mathrm{L}(\pi)=.3497,\ 2\mathrm{L}(\tfrac{1}{2}\pi)=.3342,$$

and

$$\frac{2\mathrm{L}(\frac{1}{2}\pi)}{\mathrm{L}(0)+\mathrm{L}(\pi)}=.955.$$

Comparison with rectangular aperture.

The corresponding number for the rectangular aperture was .811; so that, as might have been expected, the resolving power of the circular aperture is distinctly less than that of the rectangular aperture of equal width. Hence a telescope will not resolve a double line unless the angular interval between them decidedly exceeds that subtended by the wave-length of light at a distance equal to the diameter of the object-glass. Experiment shows that resolution begins when the angular interval is about a tenth part greater than that mentioned.

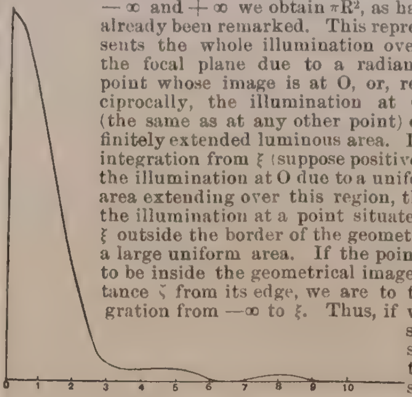

FIG. 6.

Uniform field of light terminated by straight edge.

If we integrate (30) with respect to ξ between the limits $-\infty$ and $+\infty$ we obtain $\pi\mathrm{R}^2$, as has already been remarked. This represents the whole illumination over the focal plane due to a radiant point whose image is at O, or, reciprocally, the illumination at O (the same as at any other point) due to an infinitely extended luminous area. If we take the integration from ξ (suppose positive) to ∞ we get the illumination at O due to a uniform luminous area extending over this region, that is to say, the illumination at a point situated at distance ξ outside the border of the geometrical image of a large uniform area. If the point is supposed to be inside the geometrical image and at a distance ζ from its edge, we are to take the integration from $-\infty$ to ξ. Thus, if we choose the scale of intensities so that the full intensity is unity, then the intensity at a distance corresponding to $+\zeta$ (outside the geometrical image) may be represented by $\mathfrak{J}(+\zeta)$, and that at a distance $-\zeta$ by $\mathfrak{J}(-\zeta)$, where

$$\mathfrak{J}(+\zeta)+\mathfrak{J}(-\zeta)=1,$$

and

$$\mathfrak{J}(\zeta)=\frac{1}{2\pi}\int_\zeta^\infty\zeta^{-3}d\zeta\,\mathrm{K}_1(2\zeta)=\tfrac{1}{2}-\frac{1}{2\pi}\int_0^\zeta\zeta^{-3}d\zeta\,\mathrm{K}_1(2\zeta)\quad (36).$$

This is the result obtained by Struve, who gives the following series for $\mathfrak{J}(\zeta)$.

Struve's results.

The ascending series, obtained at once by integration from (33), is

$$\mathfrak{J}(\zeta)=\tfrac{1}{2}-\frac{2}{\pi^2}\sum_{n=1}^{n=\infty}(-1)^{n-1}\frac{2n+1}{2n-1}\,\frac{2^{2n}\zeta^{2n-1}}{1^2.3^2.5^2\ldots(2n+1)^2}\quad (37).$$

When ζ is great, we have approximately from the descending series

$$\mathfrak{J}(\zeta)=\frac{2}{\pi^2}\left(\frac{1}{\zeta}+\frac{1}{12\zeta^2}\right)-\frac{1}{2\pi^{3/2}}\,\frac{\cos(2\zeta+\frac{1}{4}\pi)}{\zeta^{5/2}}.$$

Thus "at great distances from the edge of the geometrical image the intensity is inversely proportional to the distance, and to the radius of the object-glass."

The following table, abbreviated from that given by Struve, will serve to calculate the enlargement of an image due to diffraction in any case that may arise.

$$\zeta=2\pi\mathrm{R}\xi/\lambda f.$$

$$\mathfrak{J}(-\zeta)=1-\mathfrak{J}(+\zeta).$$

ζ	$\mathfrak{J}(\zeta)$	ζ	$\mathfrak{J}(\zeta)$	ζ	$\mathfrak{J}(\zeta)$
0.0	.5000	2.5	.0765	7.0	.0293
0.5	.3678	3.0	.0630	9.0	.0222
1.0	.2521	4.0	.0528	11.0	.0186
1.5	.1642	5.0	.0410	15.0	.0135
2.0	.1073	6.0	.0328		

Integration of intensity further considered.

It may perhaps have struck the reader that there is some want of rigor in our treatment of (30) when we integrate it over the whole focal plane of ξ, η, inasmuch as in the proof of the formulæ ξ and η are supposed to be small. The inconsistency becomes very apparent when we observe that according to the formulæ there is no limit to the relative retardation of secondary waves coming from various parts of the aperture, whereas in reality this retardation could never exceed the longest line capable of being drawn within the aperture. It will be worth while to consider this point a little further, although our limits forbid an extended treatment.

---

[1] *Theory of Sound*, § 302.

[2] *Ann. d. l'École Normale*, v. p. 310, 1876.

The formula becomes rigorous if we regard it as giving the illumination on the surface of a sphere of very large radius f, in a direction such that

$$\xi = f \sin\theta\cos\phi,\ \eta = f\sin\theta\sin\phi\,;$$

it may then be written

$$I^2 = \lambda^{-2} f^{-2} \iiiint \cos\kappa\left\{(x'-x)\sin\theta\cos\phi + (y'-y)\sin\theta\sin\phi\right\} dx\,dy\,dx'\,dy'.$$

The whole intensity over the infinite hemisphere is given by

$$\mathfrak{J} = f^2 \int_0^{\frac{1}{2}\pi}\int_0^{2\pi} I^2 \sin\theta\, d\theta\, d\phi \quad . \quad . \quad . \quad . \quad (38).$$

According to the plan formerly adopted, we postpone the integration with respect to x, y, x', y', and take first that with respect to θ and ϕ. Thus for a single pair of elements of area $dx\ dy$, $dx'\ dy'$ we have to consider

$$\iint \cos\kappa\left\{x'-x)\sin\theta\cos\phi + (y'-y)\sin\theta\sin\phi\right\}\sin\theta\, d\theta\, d\phi,$$

or, if we write

$$x'-x = r\cos a,\ y'-y = r\sin a,$$

$$\int_0^{\frac{1}{2}\pi}\int_0^{2\pi} \cos(\kappa r\sin\theta\cos\phi)\sin\theta\, d\theta\, d\phi.$$

Now it may be proved (*e.g.*, by expansion in powers of κr) that

$$\int_0^{\frac{1}{2}\pi}\int_0^{2\pi} \cos(\kappa r\sin\theta\cos\phi)\sin\theta\, d\theta\, d\phi = 2\pi\frac{\sin\kappa r}{\kappa r} \qquad (39)\,;$$

and thus

$$\mathfrak{J} = \frac{2\pi}{\lambda^2}\iiiint \frac{\sin\kappa r}{\kappa r}\, dx\, dy\, dx'\, dy' \quad . \quad . \quad (40),$$

r being the distance between the two elements of area $dx\ dy$, $dx'\ dy'$.

In the case of a circular area of radius R, we have[1]

$$\iiiint \frac{\sin\kappa r}{\kappa r}\, dx\, dy\, dx'\, dy' = \frac{2\pi R^2}{\kappa^2}\left\{1 - \frac{J_1(2\kappa R)}{\kappa R}\right\},$$

and thus

$$\mathfrak{J} = \pi R^2\left\{1 - \frac{J_1(2\kappa R)}{\kappa R}\right\} \quad . \quad . \quad . \quad . \quad . \quad (41).$$

When $\kappa R = \infty$,

$$\mathfrak{J} = \pi R^2, \text{ as before.}$$

It appears therefore that according to the assumed law of the secondary wave the total illumination is proportional to the area of aperture, only under the restriction that the linear dimensions of the aperture are very large in comparison with the wave-length.

A word as to the significance of (39) may not be out of place. We know that

$$\psi = \cos\kappa\left\{\sin\theta\cos\phi x + \sin\theta\sin\phi y + \cos\theta z\right\} \quad . \quad (42)$$

satisfies Laplace's extended equation $(\Delta^2 + \kappa^2)\psi = 0$, being of the form $\cos\kappa x'$, where x' is drawn in an oblique direction; and it follows that $\iint \psi \sin\theta\ d\theta\ d\phi$ satisfies the same equation. Now this, if the integration be taken over the hemisphere $\theta = 0$ to $\theta = \frac{1}{2}\pi$, must become a function of r, or $\sqrt{(x^2 + y^2 + z^2)}$, only.

Hence, putting $x = r$, $y = 0$, $z = 0$, we get

$$\iint \psi\sin\theta\, d\theta\, d\phi = \int_0^{\frac{1}{2}\pi}\int_0^{2\pi} \cos(\kappa r\sin\theta\cos\phi)\sin\theta\, d\theta\, d\phi.$$

But the only function of r which satisfies Laplace's equation continuously through the origin is $A \sin\kappa r/(\kappa r)$; and that $A = 2\pi$ is proved at once by putting $r = 0$. The truth of the formula may also be established independently of the differential equation by equating the values of $\int_0^{\frac{1}{2}\pi}\int_0^{2\pi}\psi\sin\theta\, d\theta\, d\phi$, when $x = r$, $y = 0$, $z = 0$, and when $x = 0$, $y = 0$, $z = r$. Thus

$$\int_0^{\frac{1}{2}\pi}\int_0^{2\pi} \cos(\kappa r\sin\theta\cos\phi)\sin\theta\, d\theta\, d\phi = \int_0^{\frac{1}{2}\pi}\int_0^{2\pi} \cos(\kappa r\cos\theta)\sin\theta\, d\theta\, d\phi = 2\pi\frac{\sin\kappa r}{\kappa r}.$$

The formula itself may also be written

$$\int_0^{\frac{1}{2}\pi} J_0(\kappa r\sin\theta)\sin\theta\, d\theta = \frac{\sin\kappa r}{\kappa r} \quad . \quad . \quad . \quad (43).$$

Coronas or glories.

The results of the preceding theory of circular apertures admit of an interesting application to *coronas*, such as are often seen encircling the sun and moon. They are due to the interposition of small spherules of water, which act the part of diffracting obstacles. In order to the formation of a well-defined corona it is essential that the particles be exclusively, or preponderatingly, of one size.

If the origin of light be treated as infinitely small, and be seen in focus, whether with the naked eye or with the aid of a telescope, the whole of the light in the absence of obstacles would be concentrated in the immediate neighborhood of the focus. At other parts of the field the effect is the same, by Babinet's principle, whether the imaginary screen in front of the object-glass is generally transparent but studded with a number of opaque circular disks, or is generally opaque but perforated with corresponding apertures. Consider now the light diffracted in a direction many times more oblique than any with which we should be concerned, were the whole aperture uninterrupted, and take first the effect of a single small aperture. The light in the proposed direction is that determined by the size of the small aperture in accordance with the laws already investigated, and its phase depends upon the position of the aperture. If we take a direction such that the light (of given wave-length) from a single aperture vanishes, the evanescence continues even when the whole series of apertures is brought into contemplation. Hence, whatever else may happen, there must be a system of dark rings formed, the same as from a single small aperture. In directions other than these it is a more delicate question how the partial effects should be compounded. If we make the extreme suppositions of an infinitely small source and absolutely homogeneous light, there is no escape from the conclusion that the light in a definite direction is arbitrary, that is, dependent upon the chance distribution of apertures. If, however, as in practice, the light be heterogeneous, the source of finite area, the obstacles in motion, and the discrimination of different directions imperfect, we are concerned merely with the mean brightness found by varying the arbitrary phase-relations, and this is obtained by simply multiplying the brightness due to a single aperture by the number of apertures(n).[2] The diffraction pattern is therefore that due to a single aperture, merely brightened n times.

In his experiments upon this subject Fraunhofer employed plates of glass dusted over with lycopodium, or studded with small metallic disks of uniform size; and he found that the diameters of the rings were proportional to the length of the waves and inversely as the diameter of the disks.

In another respect the observations of Fraunhofer appear at first sight to be in disaccord with theory; for his measures of the diameters of the red rings, visible when white light was employed, correspond with the law applicable to dark rings, and not to the different law applicable to the luminous maxima. Verdet has, however, pointed out that the observation in this form is essentially different from that in which homogeneous red light is employed, and that the position of the red rings would correspond to the *absenee* of blue-green light rather than to the greatest abundance of red light. Verdet's own observations, conducted with great care, fully confirm this view, and exhibit a complete agreement with theory.

By measurements of coronas it is possible to infer the size of the particles to which they are due, an application of considerable interest in the case of natural corona—the general rule being the larger the corona the smaller the water spherules. Young employed this method not only to determine the diameters of cloud particles (*e.g.*, $\frac{1}{1000}$ inch), but also those of fibrous material, for which the theory is analogous. His instrument was called the *eriometer*.[3]

§ 13. *Influence of Aberration. Optical Power of Instruments.*

Optical errors.

Our investigations and estimates of resolving power have thus far proceeded upon the supposition that there are no optical imperfections, whether of the nature of a regular aberration or dependent upon irregularities of material and workmanship. In practice there will always be a certain aberration or error of phase, which we may also regard as the deviation of the actual wave-surface from its intended position. In general, we may say that aberration is unimportant, when it nowhere (or at any rate over a relatively small area only) exceeds a small fraction of the wave-length (λ). Thus in estimating the intensity at a focal point, where, in the absence of aberration, all the secondary waves would have exactly the same phase, we see that an aberration nowhere exceeding $\frac{1}{4}\lambda$ can have but little effect.

---

[1] *Theory of Sound*, § 302.

[2] See § 4.

[3] "Chromatics," in vol. iii. of Supp. to *Ency. Brit.*, 1817.

Unsymmetrical aberration.

The only case in which the influence of small aberration upon the entire image has been calculated[1] is that of a rectangular aperture, traversed by a cylindrical wave with aberration equal to cx^3. The aberration is here unsymmetrical, the wave being in advance of its proper place in one half of the aperture, but behind in the other half. No terms in x or x^2 need be considered. The first would correspond to a general turning of the beam; and the second would imply imperfect focusing of the central parts. The effect of aberration may be considered in two ways. We may suppose the aperture (a) constant, and inquire into the operation of an increasing aberration; or we may take a given value of c (*i.e.*, a given wave-surface) and examine the effect of a varying aperture. The results in the second case show that an increase of aperture up to that corresponding to an extreme aberration of half a period has no ill effect upon the central band (§ 11), but it increases unduly the intensity of one of the neighboring lateral bands; and the practical conclusion is that the best results will be obtained from an aperture giving an extreme aberration of from a quarter to half a period, and that with an increased aperture aberration is not so much a direct cause of deterioration as an obstacle to the attainment of that improved definition which should accompany the increase of aperture.

If, on the other hand, we suppose the aperture given, we find that aberration begins to be distinctly mischievous when it amounts to about a quarter period, *i.e.*, when the wave-surface deviates at each end by a quarter wave-length from the true plane.

Circular aperture. Symmetrical aberration.

For the focal point itself the calculations are much simpler. We will consider the case of a circular object-glass with a symmetrical aberration proportional to $h\rho^4$. The vibration will be represented by

$$2\int_0^1 \cos(nt - h\rho^4)\rho d\rho,$$

in which the radius of the aperture is supposed to be unity. The intensity is thus expressed by

$$I_0^2 = \left[2\int_0^1 \cos(h\rho^4)\rho\, d\rho\right]^2 + \left[2\int_0^1 \sin(h\rho^4)\rho\, d\rho\right]^2 . \quad (1),$$

the scale being such that the intensity is unity when there is no aberration ($h=0$).

By integration by parts it can be shown that

$$2\int_0^1 e^{ih\rho^4}\rho\, d\rho = e^{ih}\left\{1 - \frac{4ih}{6} + \frac{(4ih)^2}{6.10} - \frac{(4ih)^3}{6.10.14} + \dots\right\};$$

so that

$$2\int_0^1 \cos(h\rho^4)\rho\, d\rho = \cos h\left\{1 - \frac{(4h)^2}{6.10} + \frac{(4h)^4}{6.10.14.18} - \dots\right\}$$
$$+ \sin h\left\{\frac{4h}{6} - \frac{(4h)^3}{6.10.14} + \dots\right\} \quad . \quad . \quad . \quad . \quad (2),$$

$$2\int_0^1 \sin(h\rho^4)\rho\, d\rho = \sin h\left\{1 - \frac{(4h)^2}{6.10} + \frac{(4h)^4}{6.10.14.18} - \dots\right\}$$
$$- \cos h\left\{\frac{4h}{6} - \frac{(4h)^3}{6.10.14} + \dots\right\} \quad . \quad . \quad . \quad . \quad (3).$$

Hence, when $h = \frac{1}{4}\pi$,

$$2\int_0^1 \cos(\tfrac{1}{4}\pi\rho^4)\rho\, d\rho = 1.32945/\sqrt{2},$$

$$2\int_0^1 \sin(\tfrac{1}{4}\pi\rho^4)\rho\, d\rho = .35424/\sqrt{2},$$

$$I_0^2 = .9464.$$

Similarly, when $h = \frac{1}{2}\pi$,

$$I_0^2 = .8003;$$

and when $h = \pi$,

$$I_0^2 = .3947.$$

These numbers represent the influence of aberration upon the intensity at the central point, upon the understanding that the focusing is that adapted to a small aperture, for which h might be neglected. If a readjustment of focus be permitted, the numbers will be sensibly raised. The general conclusion is that an aberration between the centre and circumference of a quarter period has but little effect upon the intensity at the central point of the image.

Disturbance due to variation of temperature.

As an application of this result, let us investigate what amount of temperature disturbance in the tube of a telescope may be expected to impair definition. According to Biot and Arago, the index μ for air at $t°$ C. and at atmospheric pressure is given by

$$\mu - 1 = \frac{.00029}{1 + .0037\, t}.$$

If we take 0° C. as standard temperature,

$$\delta\mu = -1.1\, t \times 10^{-6}.$$

Thus, on the supposition that the irregularity of temperature t extends through a length l, and produces an acceleration of a quarter of a wave-length,

$$\tfrac{1}{4}\lambda = 1.1\, l\, t \times 10^{-6};$$

or, if we take $\lambda = 5.3 \times 10^{-5}$,

$$lt = 12,$$

the unit of length being the centimetre.

We may infer that, in the case of a telescope tube 12 cm. long a stratum of air heated 1° C. lying along the top of the tube, and occupying a moderate fraction of the whole volume, would produce a not insensible effect. If the change of temperature progressed uniformly from one side to the other, the result would be a lateral displacement of the image without loss of definition; but in general both effects would be observable. In longer tubes a similar disturbance would be caused by a proportionally less difference of temperature.

Images by simple apertures.

We will now consider the application of the principle to the formation of images, unassisted by reflection or refraction.[2] The function of a lens in forming an image is to compensate by its variable thickness the differences of phase which would otherwise exist between secondary waves arriving at the focal point from various parts of the aperture (OPTICS, vol. xvii. p. 825). If we suppose the diameter of the lens to be given (2R), and its focal length f gradually to increase, the original differences of phase at the image of an infinitely distant luminous point diminish without limit. When f attains a certain value, say f_1, the extreme error of phase to be compensated falls to $\frac{1}{4}\lambda$. But, as we have seen, such an error of phase causes no sensible deterioration in the definition; so that from this point onwards the lens is useless, as only improving an image already sensibly as perfect as the aperture admits of. Throughout the operation of increasing the focal length, the resolving power of the instrument, which depends only upon the aperture, remains unchanged; and we thus arrive at the rather startling conclusion that a telescope of any degree of resolving power might be constructed without an object-glass, if only there were no limit to the admissible focal length. This last proviso, however, as we shall see, takes away almost all practical importance from the proposition.

To get an idea of the magnitudes of the quantities involved, let us take the case of an aperture of $\frac{1}{5}$ inch, about that of the pupil of the eye. The distance f_1, which the actual focal length must exceed, is given by

$$\sqrt{(f_1^2 + R^2)} - f_1 = \tfrac{1}{4}\lambda;$$

so that

$$f_1 = 2R^2/\lambda \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4).$$

Thus, if $\lambda = \frac{1}{40000}$, $R = \frac{1}{10}$, we find

$$f_1 = 800 \text{ inches}.$$

The image of the sun thrown upon a screen at a distance exceeding 66 feet, through a hole $\frac{1}{5}$ inch in diameter, is therefore at least as well defined as that seen direct.

As the minimum focal length increases with the square of the aperture, a quite impracticable distance would be required to rival the resolving power of the modern telescope. Even for an aperture of 4 inches, f_1 would have to be 5 miles.

Simple *versus* achromatic lens.

A similar argument may be applied to find at what point an achromatic lens becomes sensibly superior to a single one. The question is whether, when the adjustment of focus is correct for the central rays of the spectrum, the error of phase for the most extreme rays (which it is necessary to consider) amounts to quarter of a wave-length. If not, the substitution of an achromatic lens will be of no advantage. Calculation shows that, if the aperture be $\frac{1}{5}$ inch, an achromatic lens has no sensible advantage if the focal length be greater than about 11 inches. If we suppose the focal length to be 66 feet, a single lens is practically perfect up to an aperture of 1.7 inch.

Accuracy of focusing.

Some estimates of the admissible *aberration* in a spherical lens have already been given under OPTICS, vol. xvii. p. 826. In a similar manner we may estimate the least visible displacement of the eye-piece of a telescope focused upon a distant object, a question of interest in connection with range-finders. It appears[3] that a displacement δf from the true focus will not sensibly impair definition, provided

$$\delta f < f^2\lambda/R^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5),$$

[1] "Investigations in Optics," *Phil. Mag.*, Nov., 1879.

[2] *Phil. Mag.*, March, 1881.

[3] *Phil. Mag.*, xx. p. 354, 1885.

2R being the diameter of aperture. The linear accuracy required is thus a function of the *ratio* of aperture to focal length. The formula agrees well with experiment.

Delicacy of mirror-reading.

The principle gives an instantaneous solution of the question of the ultimate optical efficiency in the method of "mirror-reading," as commonly practiced in various physical observations. A rotation by which one edge of the mirror advances $\frac{1}{4}\lambda$ (while the other edge retreats to a like amount) introduces a phase discrepancy of a whole period where before the rotation there was complete agreement. A rotation of this amount should therefore be easily visible, but the limits of resolving power are being approached; and the conclusion is independent of the focal length of the mirror, and of the employment of a telescope, provided of course that the reflected image is seen in focus, and that the full width of the mirror is utilized.

Comparison with material pointer.

A comparison with the method of a material pointer, attached to the parts whose rotation is under observation, and viewed through a microscope, is of interest. The limiting efficiency of the microscope is attained when the angular aperture amounts to 180° (MICROSCOPE, vol. xvi. p. 287; OPTICS, vol. xvii. pp. 830–1); and it is evident that a lateral displacement of the point under observation through $\frac{1}{2}\lambda$ entails (at the old image) a phase-discrepancy of a whole period, one extreme ray being accelerated and the other retarded by half that amount. We may infer that the limits of efficiency in the two methods are the same when the length of the pointer is equal to the width of the mirror.

Admissible errors of optical surfaces.

An important practical question is the amount of error admissible in optical surfaces. In the case of a mirror, reflecting at nearly perpendicular incidence, there should be no deviation from truth (over any appreciable area) of more than $\frac{1}{8}\lambda$. For glass, $\mu-1=\frac{1}{2}$ nearly; and hence the admissible error in a refracting surface of that material is four times as great.

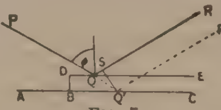

FIG. 7.

In the case of oblique reflection at an angle ϕ, the error of retardation due to an elevation BD (Fig. 7) is

$$QQ'-QS=BD\sec\phi(1-\cos SQQ')=BD\sec\phi(1+\cos2\phi)=2BD\cos\phi;$$

from which it follows that an error of given magnitude in the figure of a surface is less important in oblique than in perpendicular reflection. It must, however, be borne in mind that errors can sometimes be compensated by altering adjustments. If a surface intended to be flat is affected with a slight general curvature, a remedy may be found in an alteration of focus, and the remedy is the less complete as the reflection is more oblique.

Optical power of prisms.

The formula expressing the optical power of prismatic spectroscopes is given with examples under OPTICS, vol. xvii. p. 831, and may readily be investigated upon the principles of the wave theory. Let A_0B_0 (Fig. 8) be a plane wave-surface of the light before it falls upon the prisms, AB the corresponding wave-surface for a particular part of the spectrum after the light has passed the prisms, or after it has passed the eye-piece of the observing telescope. The path of a ray from the wave-surface A_0B_0 to A or B is determined by the condition that the optical distance, $\int \mu\, ds$, is a minimum (OPTICS, vol. xvii. p. 821); and, as AB is by supposition a wave-surface, this optical distance is the same for both points. Thus

FIG. 8.

$$\int \mu\, ds\,(\text{for A})=\int \mu\, ds\,(\text{for B})\quad . \quad . \quad . \quad . \quad (6).$$

We have now to consider the behavior of light belonging to a neighboring part of the spectrum. The path of a ray from the wave-surface A_0B_0 to the point A is changed; but in virtue of the minimum property the change may be neglected in calculating the optical distance, as it influences the result by quantities of the second order only in the changes of refrangibility. Accordingly, the optical distance from A_0B_0 to A is represented by $\int(\mu+\delta\mu)ds$, the integration being along the original path $A_0 \ldots A$; and similarly the optical distance between A_0B_0 and B is represented by $\int(\mu+\delta\mu)ds$, the integration being along $B_0 \ldots B$. In virtue of (6) the difference of the optical distances to A and B is

$$\int \delta\mu\, ds\quad(\text{along } B_0 \ldots B)-\int \delta\mu\, ds\quad(\text{along } A_0 \ldots A)\quad(7).$$

The new wave-surface is formed in such a position that the optical distance is constant; and therefore the *dispersion*, or the angle through which the wave surface is turned by the change of refrangibility, is found simply by dividing (7) by the distance AB. If, as in common flint-glass spectroscopes, there is only one dispersing substance, $\int \delta\mu\, ds=\delta\mu . s$, where s is simply the thickness traversed by the ray. If t_2 and t_1 be the thicknesses traversed by the extreme rays, and a denote the width of the emergent beam the dispersion θ is given by

$$\theta=\delta\mu(t_2-t_1)/a,$$

or, if t_1 be negligible,

$$\theta=\delta\mu\, t/a\quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8).$$

The condition of resolution of a double line whose components subtend an angle θ is that θ must exceed λ/a. Hence, in order that a double line may be resolved whose components have indices μ and $\mu+\delta\mu$, it is necessary that t should exceed the value given by the following equation:

$$t=\lambda/\delta\mu\quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9).$$

For applications of these results, see SPECTROSCOPE.

§ 14. *Theory of Gratings.*

The general explanation of the mode of action of gratings has been given under LIGHT (vol. xiv. p. 612). If the grating be composed of alternate transparent and opaque parts, the question may be treated by means of the general integrals (§ 11) by merely limiting the integration to the transparent parts of the aperture. For an investigation upon these lines the reader is referred to Airy's *Tracts* and to Verdet's *Leçons*. If, however, we assume the theory of a simple rectangular aperture (§ 11), the results of the ruling can be inferred by elementary methods, which are perhaps more instructive.

Apart from the ruling, we know that the image of a mathematical line will be a series of narrow bands, of which the central one is by far the brightest. At the middle of this band there is complete agreement of phase among the secondary waves. The dark lines which separate the bands are the places at which the phases of the secondary wave range over an integral number of periods. If now we suppose the aperture AB to be covered by a great number of opaque strips or bars of width d, separated by transparent intervals of width a, the condition of things in the directions just spoken of is not materially changed. At the central point there is still complete agreement of phase; but the amplitude is diminished in the ratio of $a : a+d$. In another direction, making a small angle with the last, such that the projection of AB upon it amounts to a few wave-lengths, it is easy to see that the mode of interference is the same as if there were no ruling. For example, when the direction is such that the projection of AB upon it amounts to one wave-length, the elementary components neutralize one another, because their phases are distributed symmetrically, though discontinuously, round the entire period. The only effect of the ruling is to diminish the amplitude in the ratio $a : a+d$; and, except for the difference in illumination, the appearance of a line of light is the same as if the aperture were perfectly free.

The lateral (spectral) images occur in such directions that the projection of the element $(a+d)$ of the grating upon them is an exact multiple of λ. The effect of each of the n elements of the grating is then the same; and, unless this vanishes on account of a particular adjustment of the ratio $a : d$, the resultant amplitude becomes comparatively very great. These directions, in which the retardation between A and B is exactly $mn\lambda$, may be called the principal directions. On either side of any one of them the illumination is distributed according to the same law as for the central image $(m=0)$, vanishing, for example, when the retardation amounts to $(mn \pm 1)\lambda$. In considering the relative brightnesses of the different spectra, it is therefore sufficient to attend merely to the principal directions, provided that the whole deviation be not so great that its cosine differs considerably from unity.

Brightness.

We have now to consider the amplitude due to a single element, which we may conveniently regard as composed of a transparent part a bounded by two opaque parts of width $\frac{1}{2}d$. The phase of the resultant effect is by symmetry that of the component which comes from the middle of a. The fact that the other components have phases differing from this by amounts ranging between $\pm am\pi/(a+d)$ causes the resultant amplitude to be less than for the central image (where there is complete phase agreement). If B_m denote the brightness of the m^{th} lateral image, and B_0 that of the central image, we have

$$B_m : B_0 = \left[\int_{-\frac{am\pi}{a+d}}^{+\frac{am\pi}{a+d}} \cos x\, dx \div \frac{2am\pi}{a+d}\right]^2$$

$$= \left(\frac{a+d}{am\pi}\right)^2 \sin^2\frac{am\pi}{a+d} \quad . \quad . \quad . \quad . \quad . \quad (1).$$

If B denote the brightness of the central image when the whole of the space occupied by the grating is transparent, we have

$$B_0 : B = a^2 : (a+d)^2,$$

and thus

$$B_m : B = \frac{1}{m^2\pi^2}\sin^2\frac{am\pi}{a+d} \quad . \quad . \quad . \quad . \quad . \quad (2).$$

The sine of an angle can never be greater than unity; and consequently under the most favorable circumstances only $1/m^2\pi^2$ of the original light can be obtained in the m^{th} spectrum. We conclude that, with a grating composed of transparent and opaque parts, the utmost light obtainable in any one spectrum is in the first, and there amounts to $1\pi^2$ or about $\frac{1}{10}$, and that for this purpose a and d must be equal. When $d = a$, the general formula becomes

Equal opaque and transparent parts.

$$B_m : B = \frac{\sin^2 \frac{1}{2}m\pi}{m^2\pi^2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

showing that, when m is even, B_m vanishes, and that when m is odd,

$$B_m : B = 1/m^2\pi^2.$$

The third spectrum has thus only $\frac{1}{9}$ of the brilliancy of the first.

Another particular case of interest is obtained by supposing a small relatively to $(a+d)$. Unless the spectrum be of very high order, we have simply

Transparent parts small.

$$B_m : B = \{\, a/(a+d) \,\}^2 \quad . \quad . \quad . \quad . \quad . \quad (4);$$

so that the brightnesses of all the spectra are the same.

The light stopped by the opaque parts of the grating, together with that distributed in the central image and lateral spectra, ought to make up the brightness that would be found in the central image, were all the apertures transparent. Thus, if $a = d$, we should have

$$1 = \frac{1}{2} + \frac{1}{4} + \frac{2}{\pi^2}\left(1 + \frac{1}{9} + \frac{1}{25} + \ldots\right),$$

which is true by a known theorem. In the general case

$$\frac{a}{a+d} = \left(\frac{a}{a+d}\right)^2 + \frac{2}{\pi^2}\sum_{m=1}^{m=\infty}\frac{1}{m^2}\sin^2\left(\frac{m\pi a}{a+d}\right),$$

a formula which may be verified by Fourier's theorem.

According to a general principle formulated by Babinet, the brightness of a lateral spectrum is not affected by an interchange of the transparent and opaque parts of the grating. The vibrations corresponding to the two parts are precisely antagonistic, since if both were operative the resultant would be zero. So far as the application to gratings is concerned, the same conclusion may be derived from (2).

Babinet's principle.

From the value of $B_m : B_0$ we see that no lateral spectrum can surpass the central image in brightness; but this result depends upon the hypothesis that the ruling acts by opacity which is generally very far from being the case in practice. In an engraved glass grating there is no opaque material present by which light could be absorbed, and the effect depends upon a difference of retardation in passing the alternate parts. It is possible to prepare gratings which give a lateral spectrum brighter than the central image, and the explanation is easy. For if the alternate parts were equal and alike transparent, but so constituted as to give a relative retardation of $\frac{1}{2}\lambda$, it is evident that the central image would be entirely extinguished, while the first spectrum would be four times as bright as if the alternate parts were opaque. If it were possible to introduce at every part of the aperture of the grating an arbitrary retardation, all the light might be concentrated in any desired spectrum. By supposing the retardation to vary uniformly and continuously we fall upon the case of an ordinary prism; but there is then no diffraction spectrum in the usual sense. To obtain such it would be necessary that the retardation should gradually alter by a wave-length in passing over any element of the grating, and then fall back to its previous value, thus springing suddenly over a wave-length. It is not likely that such a result will ever be fully attained in practice; but the case is worth stating, in order to show that there is no theoretical limit to the concentration of light of assigned wave-length in one spectrum, and as illustrating the frequently observed unsymmetrical character of the spectra on the two sides of the central image.[1]

Gratings acting by retardation.

The whole light in one spectrum.

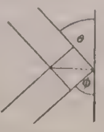

FIG. 9.

We have hitherto supposed that the light is incident perpendicularly upon the grating; but the theory is easily extended. If the incident rays make an angle θ with the normal (Fig. 9), and the diffracted rays make an angle ϕ (upon the same side), the relative retardation from each element of width $(a+d)$ to the next is $(a+d)$ $(\sin\,\theta + \sin\phi)$; and this is the quantity which is to be equated to $m\lambda$. Thus

Oblique incidence.

$$(\sin\theta + \sin\phi = 2\sin\tfrac{1}{2}(\theta+\phi).\cos\tfrac{1}{2}(\theta-\phi) = m\lambda/(a+d)\,. \quad (5).$$

The "deviation" is $(\theta + \phi)$, and is therefore a minimum when $\theta = \phi$, *i.e.*, when the grating is so situated that the angles of incidence and diffraction are equal.

In the case of a reflection grating the same method applies. If θ and ϕ denote the angles with the normal made by the incident and diffracted rays, the formula (5) still holds, and if the deviation be reckoned from the direction of the regularly reflected rays, it is expressed as before by $(\theta + \phi)$, and is a minimum when $\theta = \phi$, that is when the diffracted rays return upon the course of the incident rays.

Reflecting grating.

In either case (as also with a prism) the position of minimum deviation leaves the width of the beam unaltered, *i.e.*, neither magnifies nor diminishes the angular width of the object under view.

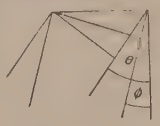

FIG. 10.

From (5) we see that, when the light falls perpendicularly upon a grating ($\theta = 0$), there is no spectrum formed (the image corresponding to $m = 0$ not being counted as a spectrum), if the grating interval σ or $(a+d)$ is less than λ. Under these circumstances, if the material of the grating be completely transparent, the whole of the light must appear in the direct image, and the ruling is not perceptible. From the absence of spectra Fraunhofer argued that there must be a microscopic limit represented by λ; and the inference is plausible, to say the least.[2] Fraunhofer should, however, have fixed the microscopic limit at $\frac{1}{2}\lambda$, as appears from (5), when we suppose $\theta = \frac{1}{2}\pi$, $\phi = \frac{1}{2}\pi$.

Grating interval less than λ.

We will now consider the important subject of the resolving power of gratings, as dependent upon the number of lines (n) and the order of the spectrum observed (m). Let BP (Fig. 11) be the direction of the principal maximum (middle of central band) for the wave-length λ in the m^{th} spectrum. Then the relative retardation of the extreme rays (corresponding to the edges A, B of the grating) is $mn\lambda$. If BQ be the direction for the first minimum (the darkness between the central and first lateral band), the relative retardation of the extreme rays is $(mn + 1\ \lambda$. Suppose now that $\lambda + \delta\lambda$ is the wave-length for which BQ gives the principal maximum, then

Resolving power.

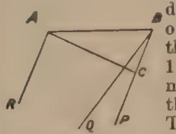

FIG 11.

$$(mn + 1)\lambda = mn(\lambda + \delta\lambda);$$

whence

$$\delta\lambda/\lambda = 1/mn \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6).$$

According to our former standard, this gives the smallest difference of wave-lengths in a double line which can be just resolved; and we conclude that the resolving power of a grating depends only upon the total number of lines, and upon the order of the spectrum, without regard to any other considerations. It is here of course assumed that the n lines are really utilized.

In the case of the D-lines the value of $\delta\lambda/\lambda$ is about 1/1000; so that to resolve this double line in the first spectrum requires 1000 lines, in the second spectrum 500, and so on.

It is especially to be noticed that the resolving power does not depend directly upon the closeness of the ruling. Let us take the case of a grating 1 inch broad, and containing 1000 lines, and consider the effect of interpolating an additional 1000 lines, so as to bisect the former intervals. There will be destruction by interference of the first, third, and odd spectra generally; while the advantage gained in the spectra of even order is not in dispersion, nor in resolving power, but simply in brilliancy, which is increased four times. If we now suppose half the grating cut away, so as to leave 1000 lines in half an inch, the dispersion will not be altered, while the brightness and resolving power are halved.

---

[1] *Phil. Mag.*, xlvii. 193, 1874.

[2] "Notes on Some Fundamental Propositions in Optics," *Phil. Mag.*, June, 1886.

No theoretical limit.

There is clearly no theoretical limit to the resolving power of gratings, even in spectra of given order. But it is possible that, as suggested by Rowland,[1] the structure of natural spectra may be too coarse to give opportunity for resolving powers much higher than those now in use. However this may be, it would always be possible, with the aid of a grating of given resolving power, to construct artificially from white light mixtures of slightly different wave-length whose resolution or otherwise would discriminate between powers inferior and superior to the given one.[2]

Expression for "dispersion."

If we define as the "dispersion" in a particular part of the spectrum the ratio of the angular interval $d\theta$ to the corresponding increment of wave-length $d\lambda$, we may express it by a very simple formula. For the alteration of wave-length entails, at the two limits of a diffracted wave-front, a relative retardation equal to $mnd\lambda$. Hence, if a be the width of the diffracted beam, and $d\theta$ the angle through which the wave-front is turned,

$$a d\theta = mnd\lambda,$$

or

$$\text{dispersion} = mn/a \quad . \quad . \quad . \quad . \quad . \quad . \quad (7).$$

The resolving power and the width of the emergent beam fix the optical character of the instrument. The latter element must eventually be decreased until less than the diameter of the pupil of the eye. Hence a wide beam demands treatment with further apparatus (usually a telescope) of high magnifying power.

Accuracy of ruling.

In the above discussion it has been supposed that the ruling is accurate, and we have seen that by increase of m a high resolving power is attainable with a moderate number of lines. But this procedure (apart from the question of illumination) is open to the objection that it makes excessive demands upon accuracy. According to the principle already laid down, it can make but little difference in the principal direction corresponding to the first spectrum, provided each line lie within a quarter of an interval $(a + d)$ from its theoretical position. But to obtain an equally good result in the mth spectrum, the error must be less than $1/m$ of the above amount.[3]

Approximate periodicity.

There are certain errors of a systematic character which demand special consideration. The spacing is usually effected by means of a screw, to each revolution of which corresponds a large number (*e.g.*, one hundred) of lines. In this way it may happen that, although there is almost perfect periodicity with each revolution of the screw after (say) 100 lines, yet the 100 lines themselves are not equally spaced. The "ghosts" thus arising were first described by Quincke,[4] and have been elaborately investigated by Peirce,[5] both theoretically and experimentally. The general nature of the effects to be expected in such a case may be made clear by means of an illustration already employed for another purpose. Suppose two similar and accurately ruled transparent gratings to be superposed in such a manner that the lines are parallel. If the one set of lines exactly bisect the intervals between the others, the grating interval is practically halved, and the previously existing spectra of odd order vanish. But a very slight relative displacement will cause the apparition of the odd spectra. In this case there is approximate periodicity in the half interval, but complete periodicity only after the whole interval. The advantage of approximate bisection lies in the superior brilliancy of the surviving spectra; but in any case the compound grating may be considered to be perfect in the longer interval, and the definition is as good as if the bisection were accurate.

Gradually increasing interval.

The effect of a gradual increase in the interval (Fig. 12) as we pass across the grating has been investigated by Cornu,[6] who thus explains an anomaly observed by Mascart. The latter found that certain gratings exercised a converging power upon the spectra formed upon one side, and a corresponding diverging power upon the spectra on the other side. Let us suppose that the light is incident perpendicularly, and that the grating interval increases from the centre towards that edge which lies nearest to the spectrum under observation, and decreases towards the hinder edge. It is evident that the waves from *both* halves of the grating are accelerated in an increasing degree, as we pass from the centre outwards, as compared with the phase they would possess were the central value of the grating interval maintained throughout. The irregularity of spacing has thus the effect of a convex lens, which accelerates the marginal relatively to the central rays. On the other side the effect is reversed. This kind of irregularity may clearly be present in a degree surpassing the usual limits, without loss of definition, when the telescope is focused so as to secure the best effect.

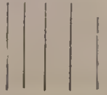

FIG. 12.—x^2.

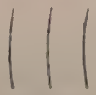

FIG. 13.—y^2.

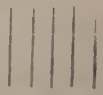

FIG. 14.—x^3.

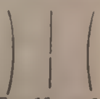

FIG. 15.—xy^2.

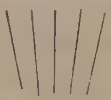

FIG. 16.—xy.

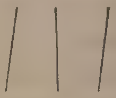

FIG. 17.—x^2y.

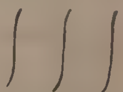

FIG. 18.—y^3.

It may be worth while to examine further the other variations from correct ruling which correspond to the various terms expressing the deviation of the wave-surface from a perfect plane. If x and y be co-ordinates in the plane of the wave-surface, the axis of y being parallel to the lines of the grating, and the origin corresponding to the centre of the beam, we have as an approximate equation to the wave-surface (§ 6)

$$z = \frac{x^2}{2\rho} + \beta xy + \frac{y^2}{2\rho'} + \alpha x^3 + \beta x^2 y + \gamma xy^2 + \delta y^3 + \qquad (8);$$

Curvature.

and, as we have just seen, the term in x^2 corresponds to a linear error in the spacing. In like manner, the term in y^2 corresponds to a general *curvature* of the lines (Fig. 13), and does not influence the definition at the (primary) focus, although it may introduce astigmatism.[7] If we suppose that everything is symmetrical on the two sides of the primary plane $y = 0$, the coefficients B, β, δ vanish. In spite of any inequality between ρ and ρ', the definition will be good to this order of approximation, provided α and γ vanish. The former measures the *thickness* of the primary focal line, and the latter measures its *curvature*. The error of ruling giving rise to α is one in which the intervals increase or decrease in *both* directions from the centre outwards (Fig. 14), and it may often be compensated by a slight rotation in azimuth of the object-glass of the observing telescope. The term in γ corresponds to a *variation* of curvature in crossing the grating (Fig. 15).

Other errors.

When the plane zx is not a plane of symmetry, we have to consider the terms in xy, x^2y, and y^3. The first of these corresponds to a deviation from parallelism, causing the interval to alter gradually as we pass *along* the lines (Fig. 16). The error thus arising may be compensated by a rotation of the object-glass about one of the diameters $y = \pm x$. The term x^2y corresponds to a deviation from parallelism in the same direction on both sides of the central line (Fig. 17); and that in y^3 would be caused by a curvature such that there is a point of inflection at the middle of each line (Fig. 18).

All the errors, except that depending on α, and especially those depending on γ and δ, can be diminished, without loss of resolving power, by contracting the *vertical* aperture. A linear error in the spacing, and a general curvature of the lines, are eliminated in the ordinary use of a grating.

---

[1] Compare also Lippich, *Pogg. Ann.*, cxxxix. p. 465, 1870; Rayleigh, *Nature*, Oct. 2, 1873.

[2] The power of a grating to construct light of nearly definite wave-length is well illustrated by Young's comparison with the production of a musical note by reflection of a sudden sound from a row of palings. The objection raised by Herschel (*Light*, § 703) to this comparison depends on a misconception.

[3] It must not be supposed that errors of this order of magnitude are unobjectionable in all cases. The position of the middle of the bright band representative of a mathematical line can be fixed with a spider-line micrometer within a small fraction of the width of the band, just as the accuracy of astronomical observations far transcends the separating power of the instrument.

[7] "In the same way we may conclude that in flat gratings any departure from a straight line has the effect of causing the dust in the slit and the spectrum to have different foci—a fact sometimes observed" (Rowland, "On Concave Gratings for Optical Purposes," *Phil. Mag.*, September, 1883).

The explanation of the difference of focus upon the two sides as due to unequal spacing was verified by Cornu upon gratings purposely constructed with an increasing interval. He has also shown how to rule a plane surface with lines so disposed that the grating shall of itself give well-focused spectra.[1]

Rowland's concave gratings.

A similar idea appears to have guided Rowland to his brilliant invention of concave gratings, by which spectra can be photographed without any further optical appliance. In these instruments the lines are ruled upon a spherical surface of speculum metal, and mark the intersections of the surface by a system of parallel and equidistant planes, of which the middle member passes through the centre of the sphere. If we consider for the present only the primary plane of symmetry, the figure is reduced to two dimensions. Let AP (Fig. 19) represent the surface of the grating, O being the centre of the circle. Then, if Q be any radiant point and Q′ its image (primary focus) in the spherical mirror AP, we have

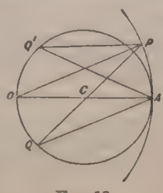

FIG. 19.

$$\frac{1}{v_1}+\frac{1}{u}=\frac{2\cos\phi}{a},$$

where $v_1 = AQ'$, $u = AQ$, $a = OA$, $\phi =$ angle of incidence QAO, equal to the angle of reflection Q′AO.[2] If Q be on the circle described upon OA as diameter, so that $u = a\cos\phi$, then Q′ lies also upon the same circle; and in this case it follows from the symmetry that the unsymmetrical aberration (depending upon α) vanishes.

This disposition is adopted in Rowland's instrument; only, in addition to the central image formed at the angle $\phi' = \phi$, there are a series of spectra with various values of ϕ', but all disposed upon the same circle. Rowland's investigation is contained in the paper already referred to; but the following account of the theory is in the form adopted by Glazebrook.[3]

In order to find the difference of optical distances between the courses QAQ′, QPQ′, we have to express QP − QA, PQ′ − AQ′. To find the former, we have, if $OAQ = \phi$, $AOP = \omega$,

$$QP^2 = u^2 + 4a^2\sin^2\tfrac{1}{2}\omega - 4au\sin\tfrac{1}{2}\omega\sin(\tfrac{1}{2}\omega-\phi)$$
$$= (u + a\sin\phi\sin\omega)^2 - a^2\sin^2\phi\sin^2\omega + 4a\sin^2\tfrac{1}{2}\omega\,(a - u\cos\phi).$$

Now as far as ω^4

$$4\sin^2\tfrac{1}{2}\omega = \sin^2\omega + \tfrac{1}{4}\sin^4\omega,$$

and thus to the same order

$$QP^2 = (u + a\sin\phi\sin\omega)^2$$
$$- a\cos\phi\,(u - a\cos\phi)\sin^2\omega + \tfrac{1}{4}a\,(a - u\cos\phi)\sin^4\omega.$$

But if we now suppose that Q lies on the circle $u = a\cos\phi$, the middle term vanishes, and we get, correct as far as ω^4,

$$QP = (u + a\sin\phi\sin\omega)\sqrt{\left\{1+\frac{a^2\sin^2\phi\sin^4\omega}{4u}\right\}};$$

so that

$$QP - u = a\sin\phi\sin\omega + \tfrac{1}{8}a\sin\phi\tan\phi\sin^4\omega \quad . \quad . \quad (9),$$

in which it is to be noticed that the adjustment necessary to secure the disappearance of $\sin^2\omega$ is sufficient also to destroy the term in $\sin^3\omega$.

A similar expression can be found for Q′P − Q′A; and thus, if $Q'A = v$, $Q'AO = \phi'$, where $v = a\cos\phi'$, we get

$$QP + PQ' - QA - AQ' = a\sin\omega(\sin\phi - \sin\phi')$$
$$+ \tfrac{1}{8}a\sin^4\omega(\sin\phi\tan\phi + \sin\phi'\tan\phi') \quad . \quad . \quad . \quad (10).$$

If $\phi' = \phi$, the term of the first order vanishes, and the reduction of the difference of path *via* P and *via* A to a term of the fourth order proves not only that Q and Q′ are conjugate foci, but also that the foci are exempt from the most important term in the aberration. In the present application ϕ' is not necessarily equal to ϕ; but if P correspond to a line upon the grating, the difference of retardations for consecutive positions of P, so far as expressed by the term of the first order, will be equal to $\mp m\lambda$ (m integral), and therefore without influence, provided

$$\sigma(\sin\phi - \sin\phi') = \mp m\lambda \quad . \quad . \quad . \quad . \quad . \quad . \quad (11),$$

where σ denotes the constant interval between the planes containing the lines. This is the ordinary formula for a reflecting plane grating, and it shows that the spectra are formed in the usual directions. They are here focused (so far as the rays in the primary plane are concerned) upon the circle OQ′A, and the outstanding aberration is of the fourth order.

In order that a large part of the field of view may be in focus at once, it is desirable that the locus of the focused spectrum should be nearly perpendicular to the line of vision. For this purpose Rowland places the eye-piece at O, so that $\phi = 0$, and then by (11) the value of ϕ' in the m^{th} spectrum is

$$\sigma\sin\phi' = \pm m\lambda \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (12).$$

Aberration.

If ω now relate to the edge of the grating, on which there are altogether n lines,

$$n\sigma = 2a\sin\omega,$$

and the value of the last term in (10) becomes

$$\tfrac{1}{16}n\sigma\sin^3\omega\sin\phi'\tan\phi',$$

or

$$\tfrac{1}{16}mn\lambda\sin^3\omega\tan\phi' \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13).$$

This expresses the retardation of the extreme relatively to the central ray, and is to be reckoned positive, whatever may be the signs of ω and ϕ'. If the semi-angular aperture (ω) be $\frac{1}{100}$, and $\tan\phi' = 1$, mn might be as great as four millions before the error of phase would reach $\frac{1}{4}\lambda$. If it were desired to use an angular aperture so large that the aberration according to (13) would be injurious, Rowland points out that on his machine there would be no difficulty in applying a remedy by making σ slightly variable towards the edges. Or, retaining σ constant, we might attain compensation by so polishing the surface as to bring the circumference slightly forward in comparision with the position it would occupy upon a true sphere.

It may be remarked that these calculations apply to the rays in the primary plane only. The image is greatly affected with astigmatism; but this is of little consequence, if γ in (8) be small enough. Curvature of the primary focal line having a very injurious effect upon definition, it may be inferred from the excellent performance of these gratings that γ is in fact small. Its value does not appear to have been calculated. The other coefficients in (8) vanish in virtue of the symmetry.

Rowland's mechanical arrangements.

The mechanical arrangements for maintaining the focus are of great simplicity. The grating at A and the eye-piece at O are rigidly attached to a bar AO, whose ends rest on carriages, moving on rails OQ, AQ at right angles to each other. A tie between C and Q can be used if thought desirable.

The absence of chromatic aberration gives a great advantage in the comparison of overlapping spectra, which Rowland has turned to excellent account in his determinations of the relative wave-lengths of lines in the solar spectrum.[4]

Absolute measurements.

For absolute determinations of wave-lengths plane gratings are used. It is found[5] that the angular measurements present less difficulty than the comparison of the grating interval with the standard metre. There is also some uncertainty as to the actual temperature of the grating when in use. In order to minimize the heating action of the light, it might be submitted to a preliminary prismatic analysis before it reaches the slit of the spectrometer, after the manner of Von Helmholtz (OPTICS, vol. xvii. p. 825.)

Bell found further that it is necessary to submit the gratings to calibration, and not to rest satisfied with a knowledge of the number of lines and of the total width. It not unfrequently happens that near the beginning of the ruling the interval is anomalous. If the width of this region be small, it has scarcely any effect upon the angular measurements, and should be left out of account in estimating the effective interval.

§ 15. *Theory of Corrugated Waves.*

The theory of gratings is usually given in a form applicable only to the case where the alternate parts are transparent and opaque. Even then it is very improbable that the process of simply including the transparent parts and excluding the opaque parts in the integrations of § 11 gives an accurate result. The condition of things in actual gratings is much more complicated, and all that can with confidence be asserted is the approximate periodicity in the interval σ. The problem thus presents itself—to determine the course of events on the further side of the plane $z=0$ when the amplitude and phase over that plane are periodic functions of x; and the first step in the solution would naturally be to determine the effect corresponding to the infinitesimal strip $y\,dx$ over which the amplitude and phase are constant. In Fig. 20 QQ′ represents the strip in question, of which the effect is to be estimated at P (0, 0, z); QR $=y$, RP $=r$, QP $=\rho$.

---

[1] The ruling required is evidently that which would be marked out by interference bands, supposing sources of light of the prescribed wave-length to be situated at the radiant point and at the desired image.

[2] This formula may be obtained as in OPTICS, vol. xvii. p. 823, equation (3), and may indeed be derived from that equation by writing $\phi' = \phi$, $\mu = -1$.

Wave diverging in two dimensions.

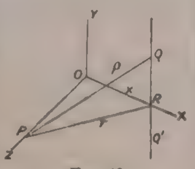

FIG. 20.

If we assume the law of secondary wave determined in § 10 so as to suit the resolution of an infinite uniform primary wave, we have, as the effect of QQ′.

$$2dx\int_0^\infty\frac{dy}{\lambda\rho}\cos\kappa(at-\rho+\tfrac{1}{4}\lambda)$$

$$=-\frac{2dx}{\lambda}\int_r^\infty\frac{d\rho}{\sqrt{(\rho^2-r^2)}}\sin\kappa(at-\rho)\;.\;\;.\;\;(1).$$

The development of this expression for the operation of a linear source would take us too far.[1] We must content ourselves with the limiting form assumed when κr is great, as it would almost always be in optics. Under these circumstances the denominator may be simplified by writing

$$\sqrt{(\rho^2-r^2)}=\sqrt{(2r)}.\sqrt{(\rho-r)},$$

so that (1) becomes

$$-\frac{2dx}{\lambda\sqrt{(2r)}}\int_0^\infty\frac{d(\rho-r)}{\sqrt{(\rho-r)}}\sin\kappa\left\{at-r-(\rho-r)\right\}.$$

Now

$$\int_0^\infty\frac{\sin\kappa u\,du}{\sqrt{u}}=\int_0^\infty\frac{\cos\kappa u\,du}{\sqrt{u}}=\sqrt{\left(\frac{\pi}{2\kappa}\right)}=\tfrac{1}{2}\sqrt{\lambda},$$

and thus we obtain

$$-\frac{dx}{\sqrt{(2\lambda r)}}\left\{\sin\kappa(at-r)-\cos\kappa(at-r)\right\}$$

$$=-\frac{dx}{\sqrt{(\lambda r)}}\sin\kappa(at-r-\tfrac{1}{8}\lambda)\;.\;\;.\;\;.\;\;.\;\;.\;\;(2),$$

which gives the effect of a linear source at a great distance. The occurrence of the factor $r^{-\frac{1}{2}}$ is a consequence of the cylindrical expansion of the waves. The whole effect is retarded *one-eighth* of a period in comparison with that of the central element, instead of one-quarter of a period as in the case of a uniform wave extending over the whole plane.

Plane uniform wave.

The effect of the uniform plane wave can be recovered by integrating (2) with respect to x from $-\infty$ to ∞, on the supposition that κr is great. We have

$$\frac{dx}{\sqrt{r}}=\frac{r\,dr}{\sqrt{r}.x}=\frac{\sqrt{r}.d(r-z)}{\sqrt{(r+z)}.\sqrt{(r-z)}};$$

and in this, since the only elements which contribute sensibly to the integral are those for which $(r-z)$ is small, we may write

$$\frac{\sqrt{r}}{\sqrt{(r+z)}}=\frac{1}{\sqrt{2}}.$$

The integral can then be evaluated by the same formula as before, and we get finally $\cos\kappa\,(at-z)$, the same as if the primary wave were supposed to advance without resolution. The recomposition of the primary wave by integration with rectangular co-ordinates is thus verified, but only under the limitation, not really required by the nature of the case, that the point at which the effect is to be estimated is distant by a very great number of wave-lengths from the plane of resolution.

Variable amplitude and phase.

We will now suppose that the amplitude and phase of the primary wave at the plane of resolution $z=0$ are no longer constants, but periodic functions of x. Instead of $\cos\kappa at$ simply, we should have to take in general

$$\text{A}\cos(px+f)\cos\kappa at+\text{B}\cos(px+g)\sin\kappa at;$$

but it will be sufficient for our purpose to consider the first term only, in which we may further put for simplicity $\text{A}=1$, $f=0$. The effect of the linear element at $x, 0$, upon a point at ξ, z, will be; according to (2),

$$-\frac{dx}{\sqrt{(\lambda r)}}\cos px\sin\kappa(at-r-\tfrac{1}{8}\lambda),$$

where r is the distance, expressed by $r^2=z^2+(x-\xi)^2$. Thus, if we write $x=\xi+a$, the whole effect is

$$\int_{-\infty}^{+\infty}\frac{da}{2\sqrt{(\lambda r)}}\left\{\sin(\kappa at+p\xi-\tfrac{1}{4}\pi-\kappa r+pa)\right.$$

$$\left.+\sin(\kappa at-p\xi-\tfrac{1}{4}\pi-\kappa r-pa)\right\}\;\;.\;\;(3);$$

where $r^2=z^2+a^2$.

In the two terms of this integral the elements are in general of rapidly fluctuating sign; and the only important part of the range of integration in (for example) the first term is in the neighborhood of the place where $pa-\kappa r$ is stationary in value, or where

$$p\,da-\kappa\,dr=0\;\;.\;\;.\;\;.\;\;.\;\;.\;\;.\;\;.\;\;(4).$$

In general $a\,da-r\,dr=0$, so that if the values of a and r corresponding to (4) be called a_0 r_0 we have

$$\frac{a_0}{p}=\frac{r_0}{\kappa}=\frac{z}{\sqrt{(\kappa^2-p^2)}}\;\;.\;\;.\;\;.\;\;.\;\;.\;\;(5).$$

Now, in the neighborhood of these values, if $a=a_0+a_1$,

$$pa-\kappa r=pa_0-\kappa r_0+a_1\left(p-\kappa\frac{a_0}{r_0}\right)-\frac{\kappa a_1^2}{2r_0}\left(1-\frac{p^2}{\kappa^2}\right),$$

in which by (5) the term of the first order vanishes. Using this in (3), we get for the first term

$$-\int_{-\infty}^{+\infty}\frac{da_1}{2\sqrt{(\lambda r_0)}}\left\{\sin(\kappa at+p\xi-\tfrac{1}{4}\pi-\kappa r_0+pa_0)\cos ha_1^2\right.$$

$$\left.-\cos(\kappa at+p\xi-\tfrac{1}{4}\pi-\kappa r_0+pa_0)\sin ha_1^2\right\},$$

where for brevity h is written for

$$\frac{\kappa}{2r_0}\left(1-\frac{p^2}{\kappa^2}\right).$$

The integration is effected by means of the formula

$$\int_{-\infty}^{+\infty}\cos hu^2du=\int_{-\infty}^{+\infty}\sin hu^2du=\sqrt{\left(\frac{\pi}{2h}\right)};$$

and we find

$$\frac{\kappa}{2\sqrt{(\kappa^2-p^2)}}\cos(\kappa at+p\xi-\kappa r_0+pa_0).$$

The other term in (3) gives in like manner

$$\frac{\kappa}{2\sqrt{(\kappa^2-p^2)}}\cos(\kappa at-p\xi-\kappa r_0+pa_0);$$

so that the complete value is

$$\frac{\kappa\cos p\xi}{\sqrt{(\kappa^2-p^2)}}\cos\left\{\kappa at-\sqrt{(\kappa^2-p^2)}.z\right\}\;\;.\;\;.\;\;.\;\;(6).$$

When $p=0$, we fall back on the uniform plane wave travelling with velocity a. In general the velocity is not a, but

Velocity of propagation.

$$\kappa/a\sqrt{(\kappa^2-p^2)}\;\;.\;\;.\;\;.\;\;.\;\;.\;\;.\;\;.\;\;.\;\;(7).$$

The wave represented by (6) is one in which the amplitude at various points of a wave-front is proportional to $\cos p\xi$, or $\cos px$; and, beyond the reversals of phase herein implied, the phase is constant, so that the wave-surfaces are given by $z=$ constant. The wave thus described moves forward at the velocity given by (7), and with type unchanged.

The above investigation may be regarded as applicable to gratings which give spectra of the first order only. Although κ vary, there is no separation of colors. Such a separation requires either a limitation in the width of the grating (here supposed to be infinite), or the use of a focusing lens.

It is important to remark that p has been assumed to be less than κ or σ greater than λ; otherwise no part of the range of integration in (3) is exempt from rapid fluctuation of sign, and the result must be considered to be zero. The principle that irregularities in a wave-front of periods less than λ cannot be propagated is of great consequence. Further light will be thrown upon it by a different investigation to be given presently.

The possibility of the wave represented by (6) is perhaps sufficiently established by the preceding method, but the occurence of the factor $\kappa/\sqrt{(\kappa^2-p^2)}$ shows that the laws of the secondary wave (determined originally from a consideration of uniform plane waves) was not rightly assumed.

Corrected law of secondary wave.

The correct law applicable in any case may be investigated as follows. Let us assume that the expression for the wave of given periodic time is

$$\psi=e^{i\kappa at}\iint\rho^{-1}e^{-i\kappa\rho}\,\text{F}(x,y)\,dx\,dy;\;\;.\;\;.\;\;.\;\;(8),$$

and let us inquire what the value of F(x, y) must be in order that the application of Huygens's principle may give a correct result. From (8)

---

[1] *Theory of Sound*, § 341.

$$\frac{d\psi}{dz}=e^{i\kappa at}\iint\frac{z}{\rho}\,\frac{d}{d\rho}\left(\frac{e^{-i\kappa\rho}}{\rho}\right)\mathrm{F}(x,y)\,dx\,dy,$$

and

$$\frac{d}{d\rho}\left(\frac{e^{-i\kappa\rho}}{\rho}\right)=-\frac{e^{-i\kappa\rho}(1+\kappa\rho)}{\rho^2}.$$

We propose now to find the limiting value of $d\psi/dz$ when z is very small. The value of the integral will depend upon those elements only for which x and y are very small, so that we replace $\mathrm{F}(x, y)$ in the limit by $\mathrm{F}(0, 0)$. Also, in the limit,

$$\iint\frac{z}{\rho}\,\frac{d}{d\rho}\left(\frac{e^{-i\kappa\rho}}{\rho}\right)dx\,dy=\iint\frac{-z}{\rho^3}\,dx\,dy=-2\pi\,;$$

so that

$$\text{Limit}\,\frac{d\psi}{dz}=-2\pi\,e^{i\kappa at}\,\mathrm{F}(0,0).$$

The proper value of $e^{i\kappa at}\mathrm{F}(x, y)$ is therefore that of $-d\psi/dz$ at the same point $(x, y, 0)$ divided by 2π, and we have in general

$$\psi=\frac{-1}{2\pi}\iint\left(\frac{d\psi}{dz}\right)\frac{e^{-i\kappa\rho}}{\rho}\,dx\,dy \quad . \quad . \quad . \quad (9).$$

In the case of the uniform plane wave,

$$\psi=e^{i\kappa(at-z)},\ d\psi/dz=-i\kappa e^{i\kappa(at-z)}\,;$$

so that

$$\psi=\frac{ie^{i\kappa at}}{\lambda}\iint\frac{e^{-i\kappa\rho}}{\rho}\,dx\,dy=\iint\frac{e^{i\kappa(at-\rho+\frac{1}{4}\lambda)}}{\lambda\rho}\,dx\,dy,$$

agreeing with what we have already found for the secondary wave in this case.

But, if $\psi=\cos px\,.\,e^{i[\kappa at-\sqrt{(\kappa^2-p^2)}\,.\,z]}$,

$$\frac{d\psi}{dz}(z=0)=-i\sqrt{(\kappa^2-p^2)}\cos px\,e^{i\kappa at},$$

and

$$\psi=\frac{\sqrt{(\kappa^2-p^2)}}{2\pi}\iint\frac{e^{i\kappa(at-\rho+\frac{1}{4}\lambda)}}{\rho}\cos px\,dx\,dy\,.$$

The occurrence of the anomalous factor in (6) is thus explained.

It must be admitted that the present process of investigation is rather artificial; and the cause lies in the attempt to dispense with the differential equation satisfied by ψ, viz.:

$$\frac{d^2\psi}{dx^2}+\frac{d^2\psi}{dy^2}+\frac{d^2\psi}{dz^2}+\kappa^2\psi=0 \quad . \quad . \quad . \quad . \quad . \quad (10),$$

on which in the case of sound the whole theory is based. It is in fact easy to verify that any value of ψ included under (8), where

$$\rho^2=(\xi-x)^2+(\eta-y)^2+\zeta^2,$$

satisfies the equation

$$\frac{d^2\psi}{d\xi^2}+\frac{d^2\psi}{d\eta^2}+\frac{d^2\psi}{d\zeta^2}+\kappa^2\psi=0.$$

When there is no question of resolution by Huygens's principle, the distinction between ξ, η and x, y may be dropped.

Starting from the differential equation, we may recover previous results very simply. If ψ be proportional to $\cos px \cos qy$, we have

$$\frac{d^2\psi}{dz^2}+(\kappa^2-p^2-q^2)\,\psi=0 \quad . \quad . \quad . \quad . \quad . \quad (11).$$

If $\kappa^2-p^2-q^2=\mu^2$, μ being real, the solution of (11) is

$$\psi=\mathrm{A}e^{i\mu z}+\mathrm{B}\,e^{-i\mu z},$$

where A and B are independent of z. Restoring the factors involving t, x, y, we may write

$$\psi=\cos px\cos qy\left\{\mathrm{A}e^{i(\kappa at+\mu z)}+\mathrm{B}\,e^{i(\kappa at-\mu z)}\right\} \quad . \quad . \quad (12),$$

of which the first term may be dropped when we contemplate waves travelling in the positive direction only. The corresponding realized solution is of the type

$$\psi=\cos px\cos qy\cos\left\{\kappa at-\sqrt{(\kappa^2-p^2-q^2)}.z\right\} \quad . \quad . \quad (13).$$

When $\kappa^2>(p^2+q^2)$, the wave travels without change of type and with velocity

$$\mathrm{V}=\frac{\kappa a}{\sqrt{(\kappa^2-p^2-q^2)}} \quad . \quad . \quad . \quad . \quad . \quad (14).$$

We have now to consider what occurs when $\kappa^2<(p^2+q^2)$. If we write $\kappa^2-p^2-q^2=-\mu^2$, we have in place of (12)

$$\psi=\cos px\cos qy\left\{\mathrm{A}e^{i\kappa at+\mu z}+\mathrm{B}\,e^{i\kappa at-\mu z}\right\} \quad . \quad . \quad (15);$$

and for the realized solution corresponding to (13)

$$\psi=\cos px\cos qy\,e^{-\mu z}\cos\kappa at \quad . \quad . \quad . \quad . \quad . \quad (16).$$

We conclude that under these circumstances the motion rapidly diminishes as z increases, and that no wave in the usual sense can be propagated at all.

Corrugations of period less than λ die out.

It follows that corrugations of a reflecting surface (no matter how deep) will not disturb the regularity of a perpendicularly reflected wave, provided the wave-length of the corrugation do not exceed that of the vibration. And, whatever the former wave length may be in relation to the latter, regular reflection will occur when the incidence is sufficiently oblique.

Shadow of a grating.

The first form of solution may be applied to give an explanation of the appearances observed when a plane wave traverses a parallel coarse grating and then impinges upon a screen held at varying distances behind.[1] As the general expression of the wave periodic with respect to x in distance σ we may take

$$\mathrm{A}_0\cos(\kappa at-\kappa z)+\mathrm{A}_1\cos(px+f_1)\cos(\kappa at-\mu_1 z)$$
$$+\,\mathrm{B}_1\cos(px+g_1)\sin(\kappa at-\mu_1 z)+\mathrm{A}_2\cos(2px+f_2)\cos\kappa(at-\mu_2 z)$$

$+\ \dots$, where

$$p=2\pi/\sigma\,,\ \kappa=2\pi/\lambda\,,\ \text{and}\ \mu_1{}^2=\kappa^2-p^2\,,\ \mu_2{}^2=\kappa^2-4p^2,\dots,$$

the series being continued as long as μ is real. We shall here, however, limit ourselves to the first three terms, and in them suppose A_1 and B_1 to be small relatively to A_0. The intensity may then be represented by

$$\mathrm{A}_0{}^2+2\mathrm{A}_0\mathrm{A}_1\cos(px+f)\cos(\kappa z-\mu_1 z)$$
$$+\,2\mathrm{A}_0\mathrm{B}_1\cos(px+g)\sin(\kappa z-\mu_1 z). \quad . \quad . \quad . \quad (17),$$

The stripes thrown upon the screen in various positions are thus periodic functions of z, and the period is

$$z=\frac{2\pi}{\kappa-\sqrt{(\kappa^2-p^2)}}=\frac{2\sigma^2}{\lambda} \quad . \quad . \quad . \quad . \quad . \quad (18),$$

if λ be supposed small in comparison with σ. It may be noticed that, if the position of the screen be altered by the half of this amount, the effect is equivalent to a shifting parallel to x through the distance $\frac{1}{2}\sigma$. Hence, if the grating consists of alternate transparent and opaque parts of width $\frac{1}{2}\sigma$, the stripes seen upon the screen are *reversed* when the latter is drawn back through the distance σ^2/λ. In this case we may suppose B_1 to vanish, and (17) then shows that the field is uniform when the screen occupies positions midway between those which give the most distinct patterns. These results are of interest in connection with the photographic reproductions of gratings.

§ 16. *Talbot's Bands.*

These very remarkable bands are seen under certain conditions when a tolerably pure spectrum is regarded with the naked eye, or with a telescope, *half the aperture being covered by a thin plate, e.g., of glass or mica.* The view of the matter taken by the discoverer[2] was that any ray which suffered in traversing the plate a retardation of an odd number of half-wave lengths would be extinguished, and that thus the spectrum would be seen interrupted by a number of dark bars. But this explanation cannot be accepted as it stands, being open to the same objection as Arago's theory of stellar scintillation.[3] It is as far as possible from being true that a body emitting homogeneous light would disappear on merely covering half the aperture of vision with a half-wave plate. Such a conclusion would be in the face of the principle of energy, which teaches plainly that the retardation in question leaves the aggregate brightness unaltered. The actual formation of the bands comes about in a very curious way, as is shown by a circumstance first observed by Brewster. When the retarding plate is held on the side towards the red of the spectrum, *the bands are not seen.* Even in the contrary case, the thickness of the plate must not exceed a certain limit, however pure the spectrum may be. A satisfactory explanation of these bands was first given by Airy,[4] but we shall here follow the investigations of Stokes,[5] limiting ourselves, however, to the case where the retarded and unretarded beams are contiguous and of equal width. The

Brewster's observations.

[2] *Phil. Mag.*, x. p. 364, 1837.

[3] On account of inequalities in the atmosphere giving a variable refraction, the light from a star would be irregularly distributed over a screen. The experiment is easily made on a laboratory scale, with a small source of light, the rays from which, in their course towards a rather distant screen, are disturbed by the neighborhood of a heated body. At a moment when the eye, or object-glass of a telescope, occupies a dark position, the star vanishes. A fraction of a second later the aperture occupies a bright place, and the star reappears. According to this view the chromatic effects depend entirely upon atmospheric dispersion.

[4] *Phil. Trans.*, 1840, p. 225 : 1841, p. 1.

[5] *Phil. Trans.*, 1848, p. 227.

aperture of the unretarded beam may thus be taken to be limited by $x = -h$, $x = 0$, $y = -l$, $y = +l$; and that of the beam retarded by R to be given by $x = 0$, $x = h$, $y = -l$, $y = +l$. For the former (1) § 11 gives

$$-\frac{1}{\lambda f}\int_{-h}^{0}\int_{-l}^{+l}\sin\kappa\left\{at - f + \frac{x\xi + y\eta}{f}dxdy\right.$$

$$= -\frac{2lh}{\lambda f}\cdot\frac{f}{\kappa\eta l}\sin\frac{\kappa\eta l}{f}\cdot\frac{2f}{\kappa\xi h}\sin\frac{\kappa\xi h}{2f}\cdot\sin\kappa\left\{at - f - \frac{\xi h}{2f}\right\} \quad . \quad (1),$$

on integration and reduction.

For the retarded stream the only difference is that we must subtract R from at, and that the limits of x are 0 and $+h$. We thus get for the disturbance at ξ, η due to this stream

$$\cdot\frac{2lh}{\lambda f}\cdot\frac{f}{\kappa\eta l}\sin\frac{\kappa\eta l}{f}\cdot\frac{2f}{\kappa\xi h}\sin\frac{\kappa\xi h}{2f}\cdot\sin\kappa\left\{at - f - \mathrm{R} + \frac{\xi h}{2f}\right\} \quad . \quad (2).$$

If we put for shortness τ for the quantity under the last circular function in (1), the expressions (1), (2) may be put under the forms $u\sin\tau$, $v\sin(\tau - a)$ respectively; and, if I be the intensity, I will be measured by the sum of the squares of the coefficients of $\sin\tau$ and $\cos\tau$ in the expression

$$u\sin\tau + v\sin(\tau - a)\ ,$$

so that

$$\mathrm{I} = u^2 + v^2 + 2uv\cos a\ ,$$

which becomes on putting for u, v, and a their values, and putting

$$\left\{\frac{f}{\kappa\eta l}\sin\frac{\kappa\eta l}{f}\right\}^2 = \mathrm{Q} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

$$\mathrm{I} = \mathrm{Q}\cdot\frac{4l^2}{\pi^2\xi^2}\sin^2\frac{\pi\xi h}{\lambda f}\left\{2 + 2\cos\left(\frac{2\pi\mathrm{R}}{\lambda} - \frac{2\pi\xi h}{\lambda f}\right)\right\} \quad . \quad . \quad (4).$$

If the subject of examination be a luminous line parallel to η, we shall obtain what we require by integrating (4) with respect to η from $-\infty$ to $+\infty$. The constant multiplier is of no especial interest, so that we may take as applicable to the image of a line

$$\mathrm{I} = \frac{2}{\xi^2}\sin^2\frac{\pi\xi h}{\lambda f}\left\{1 + \cos\left(\frac{2\pi\mathrm{R}}{\lambda} - \frac{2\pi\xi h}{\lambda f}\right)\right\} \quad . \quad . \quad . \quad (5).$$

If $\mathrm{R} = \frac{1}{2}\lambda$, I vanishes at $\xi = 0$; but the whole illumination, represented by $\int_{-\infty}^{+\infty}\mathrm{I}\,d\xi$, is independent of the value of R. If $\mathrm{R} = 0$, $\mathrm{I} = \frac{1}{\xi^2}\sin^2\frac{2\pi\xi h}{\lambda f}$, in agreement with § 11, where a has the meaning here attached to $2h$.

The expression (5) gives the illumination at ξ due to that part of the complete image whose geometrical focus is at $\xi = 0$, the retardation for this component being R. Since we have now to integrate for the whole illumination at a particular point O due to all the components which have their foci in its neighborhood, we may conveniently regard O as origin. ξ is then the co-ordinate relatively to O of any focal point O′ for which the retardation is R; and the required result is obtained by simply integrating (5) with respect to ξ from $-\infty$ to $+\infty$. To each value of ξ corresponds a different value of λ, and (in consequence of the dispersing power of the plate) of R. The variation of λ may, however, be neglected in the integration, except in $2\pi\mathrm{R}/\lambda$, where a small variation of λ entails a comparatively large alteration of phase. If we write

$$\rho = 2\pi\mathrm{R}/\lambda \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6),$$

we must regard ρ as a function of ξ, and we may take with sufficient approximation under any ordinary circumstances

$$\rho = \rho' + \varpi\xi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (7),$$

where ρ' denotes the value of ρ at O, and ϖ is a constant, which is positive when the retarding plate is held at the side on which the blue of the spectrum *is seen.* The possibility of dark bands depends upon ϖ being positive. Only in this case can

$$\cos\{\rho' + (\varpi - 2\pi h/\lambda f)\xi\}$$

retain the constant value -1 throughout the integration, and then only when

$$\varpi = 2\pi h/\lambda f \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (8),$$

and

$$\cos\rho' = -1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9).$$

The first of these equations is the condition for the formation of dark bands, and the second marks their situation, which is the same as that determined by the imperfect theory.

The integration can be effected without much difficulty. For the first term in (5) the evaluation is effected at once by a known formula. In the second term if we observe that

$$\cos\{\rho' + (\varpi - 2\pi h/\lambda f)\xi\} = \cos\{\rho' - g_1\xi\}$$
$$= \cos\rho'\cos g_1\xi + \sin\rho'\sin g_1\xi\ ,$$

we see that the second part vanishes when integrated, and that the remaining integral is of the form

$$w = \int_{-\infty}^{+\infty}\sin^2 h_1\xi\cos g_1\xi\,\frac{d\xi}{\xi^2},$$

where

$$h_1 = \pi h/\lambda f, \quad g_1 = \varpi - 2\pi h/\lambda f \quad . \quad . \quad . \quad . \quad (10).$$

By differentiation with respect to g_1 it may be proved that

$w = 0$ from $g_1 = -\infty$ to $g_1 = -2h_1$,
$w = \frac{1}{2}\pi(2h_1 + g_1)$ from $g_1 = -2h_1$ to $g_1 = 0$,
$w = \frac{1}{2}\pi(2h_1 + g_1)$ from $g_1 = 0$ to $g_1 = 2h_1$,
$w = 0$ from $g_1 = 2h_1$ to $g_1 = \infty$.

The integrated intensity, I′, or

$$2\pi h_1 + 2\cos\rho\,w\ ,$$

is thus

$$\mathrm{I}' = 2\pi h_1 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (11),$$

when g_1 numerically exceeds $2h_1$; and, when g_1 lies between $\pm 2h_1$,

$$\mathrm{I} = \pi\{2h_1 + (2h_1 - \surd g_1^2)\cos\rho'\} \quad . \quad . \quad . \quad . \quad (12).$$

Best thickness.

It appears therefore that there are no bands at all unless ϖ lies between 0 and $+4h_1$, and that within these limits the best bands are formed at the middle of the range when $\varpi = 2h_1$. The formation of bands thus requires that the retarding plate be held upon the side already specified, so that ϖ be positive; and that the thickness of the plate (to which ϖ is proportional) do not exceed a certain limit, which we may call $2\mathrm{T}_0$. At the best thickness T_0 the bands are black, and not otherwise.

The linear width of the band (e) is the increment of ξ which alters ρ by 2π, so that

$$e = 2\pi/\varpi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13).$$

With the best thickness

$$\varpi = 2\pi h/\lambda f \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (14),$$

so that in this case

$$e = \lambda f/h \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (15).$$

Width of bands.

The bands are thus of the same width as those due to two infinitely narrow apertures coincident with the central lines of the retarded and unretarded streams, the subject of examination being itself a fine luminous line.

Experimental conditions.

If it be desired to see a given number of bands in the whole or in any part of the spectrum, the thickness of the retarding plate is thereby determined, independently of all other considerations. But in order that the bands may be really visible, and still more in order that they may be black, another condition must be satisfied. It is necessary that the aperture of the pupil be accommodated to the angular extent of the spectrum, or reciprocally. Black bands will be too fine to be well seen unless the aperture ($2h$) of the pupil be somewhat contracted. One-twentieth to one-fiftieth of an inch is suitable. The aperture and the number of bands being both fixed, the condition of blackness determines the angular magnitude of a band and of the spectrum. The use of a grating is very convenient, for not only are there several spectra in view at the same time, but the dispersion can be varied continuously by sloping the grating. The slits may be cut out of tin-plate, and half covered by mica or "microscopic glass," held in position by a little cement.

Use of telescope.

If a telescope be employed there is a distinction to be observed, according as the half-covered aperture is between the eye and the ocular, or in front of the object-glass. In the former case the function of the telescope is simply to increase the dispersion, and the formation of the bands is of course independent of the particular manner in which the dispersion arises. If, however, the half-covered aperture be in front of the object-glass, the phenomenon is magnified as a whole, and the desirable relation between the (unmagnified) dispersion and the aperture is the same as without the telescope. There appears to be no further advantage in the use of a telescope than the increased facility of accommodation, and for this of course a very low power suffices.

More general investigation of Stokes.

The original investigation of Stokes, here briefly sketched, extends also to the case where the streams are of unequal width h, k, and are separated by an interval $2g$. In the case of unequal width the bands cannot be black; but if $h = k$, the finiteness of $2g$ does not preclude the formation of black bands.

The theory of Talbot's bands with a half-covered *circular* aperture has been treated by H. Struve.[1]

§ 17. *Diffraction when the Source of Light is not Seen in Focus.*

The phenomena to be considered under this head are of less importance than those investigated by Fraunhofer, and will be treated in less detail; but, in view of their historical interest and of the ease with which many of the experiments may be tried, some account of their theory could not be excluded from such a work as the present. One or two examples have already attracted our attention when considering Huygens's zones, viz., the shadow of a circular disk, and of a screen circularly perforated; but the most famous problem of this class— first solved by Fresnel—relates to the shadow of a screen bounded by a straight edge.

---

[1] *St. Petersburg Trans.*, xxxi., No. 1, 1883.

In theoretical investigations these problems are usually treated as of two dimensions only, everything being referred to the plane passing through the luminous point and perpendicular to the diffracting edges, supposed to be straight and parallel. In strictness this idea is appropriate only when the source is a luminous line, emitting cylindrical waves, such as might be obtained from a luminous point with the aid of a cylindrical lens. When, in order to apply Huygens's principle, the wave is supposed to be broken up, the phase is the same at every element of the surface of resolution which lies upon a line perpendicular to the plane of reference, and thus the effect of the whole line, or rather infinitesimal strip, is related in a constant manner (§ 15) to that of the element which lies in the plane of reference, and may be considered to be represented thereby. The same method of representation is applicable to spherical waves, issuing from a *point*, if the radius of curvature be large; for, although there is variation of phase along the length of the infinitesimal strip, the whole effect depends practically upon that of the central parts where the phase is sensibly constant.[1]

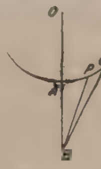

FIG. 21.

Fresnel's integrals.

In Fig. 21 APQ is the arc of the circle representative of the wave-front of resolution, the centre being at O, and the radius OA being equal to a. B is the point at which the effect is required, distant $a+b$ from O, so that AB $=b$; AP $=s$, PQ $=ds$.

Taking as the standard phase that of the secondary wave from A, we may represent the effect of PQ by

$$\cos 2\pi\left(\frac{t}{\tau}-\frac{\delta}{\lambda}\right).ds\,,$$

where $\delta=$ BP — AP is the retardation at B of the wave from P relatively to that from A.

Now

$$\delta=(a+b)s^2/2ab \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (1),$$

so that, if we write

$$\frac{2\pi\delta}{\lambda}=\frac{\pi(a+b)s^2}{ab\lambda}=\frac{\pi}{2}v^2 \quad . \quad . \quad . \quad . \quad . \quad (2),$$

the effect at B is

$$\left\{\frac{ab\lambda}{2(a+b)}\right\}^{\frac{1}{2}}\left\{\cos\frac{2\pi t}{\tau}\int\cos\tfrac{1}{2}\pi v^2.dv\right.$$
$$\left.+\sin\frac{2\pi t}{\tau}\int\sin\tfrac{1}{2}\pi v^2.\,dv\right\} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

the limits of integration depending upon the disposition of the diffracting edges. When a, b, λ are regarded as constant, the first factor may be omitted,—as indeed should be done for consistency's sake, inasmuch as other factors of the same nature have been omitted already.

The intensity I^2, the quantity with which we are principally concerned, may thus be expressed

$$I^2=\left\{\int\cos\tfrac{1}{2}\pi v^2.dv\right\}^2+\left\{\int\sin\tfrac{1}{2}\pi v^2.dv\right\}^2 \quad . \quad . \quad . \quad (4).$$

These integrals, taken from $v=0$, are known as Fresnel's integrals; we will denote them by C and S, so that

$$C=\int_0^v\cos\tfrac{1}{2}\pi v^2.dv,\quad S=\int_0^v\sin\tfrac{1}{2}\pi v^2.dv \quad . \quad . \quad (5).$$

When the upper limit is infinity, so that the limits correspond to the inclusion of half the primary wave, C and S are both equal to ½, by a known formula; and on account of the rapid fluctuation of sign the parts of the range beyond very moderate values of v contribute but little to the result.

Knockenhauer's series.

Ascending series for C and S were given by Knockenhauer, and are readily investigated. Integrating by parts, we find

$$C+iS=\int_0^v e^{i.\frac{1}{2}\pi v^2}dv=e^{i.\frac{1}{2}\pi v^2}.v-\tfrac{1}{3}i\pi\int_0^v e^{i.\frac{1}{2}\pi v^2}dv^3;$$

and, by continuing this process,

$$C+iS=e^{i.\frac{1}{2}\pi v^2}\left\{v-\frac{i\pi}{3}v^3+\frac{i\pi}{3}\frac{i\pi}{5}v^5-\frac{i\pi}{3}\frac{i\pi}{5}\frac{i\pi}{7}v^7+\dots\right\}.$$

By separation of real and imaginary parts,

$$\left.\begin{aligned}C&=M\cos\tfrac{1}{2}\pi v^2+N\sin\tfrac{1}{2}\pi v^2\\ S&=M\sin\tfrac{1}{2}\pi v^2-N\cos\tfrac{1}{2}\pi v^2\end{aligned}\right\} \quad . \quad . \quad . \quad . \quad (6),$$

where

$$M=\frac{v}{1}-\frac{\pi^2v^5}{3.5}+\frac{\pi^4v^9}{3.5.7.9}- \quad . \quad . \quad . \quad . \quad . \quad (7),$$

$$N=\frac{\pi v^3}{1.3}-\frac{\pi^3v^7}{1.3.5.7}+\frac{\pi^5v^{11}}{1.3.5.7.9.11} \quad . \quad . \quad . \quad (8).$$

These series are convergent for all values of v, but are practically useful only when v is small.

Gilbert's integrals.

Expressions suitable for discussion when v is large were obtained by Gilbert.[2] Taking

$$\tfrac{1}{2}\pi v^2=u \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (9),$$

we may write

$$C+iS=\frac{1}{\sqrt{(2\pi)}}\int_0^u\frac{e^{iu}di}{\sqrt{u}} \quad . \quad . \quad . \quad . \quad (10).$$

Again, by a known formula

$$\frac{1}{\sqrt{u}}=\frac{1}{\sqrt{\pi}}\int_0^\infty\frac{e^{-ux}dx}{\sqrt{x}} \quad . \quad . \quad . \quad . \quad (11).$$

Substituting this in (10), and inverting the order of integration, we get

$$C+iS=\frac{1}{\pi\sqrt{2}}\int_0^\infty\frac{dx}{\sqrt{x}}\int_0^u e^{u(i-x)}dx$$
$$=\frac{1}{\pi\sqrt{2}}\int_0^\infty\frac{dx}{\sqrt{x}}\,\frac{e^{u(i-x)}-1}{i-x} \quad . \quad . \quad . \quad . \quad (12).$$

Thus, if we take

$$G=\frac{1}{\pi\sqrt{2}}\int_0^\infty\frac{e^{-ux}\sqrt{x}.dx}{1+x^2},\ H=\frac{1}{\pi\sqrt{2}}\int_0^\infty\frac{e^{-ux}dx}{\sqrt{x}.(1+x^2)} \quad . \quad (13),$$

$$C=\tfrac{1}{2}-G\cos u+H\sin u,\ S=\tfrac{1}{2}-G\sin u-H\cos u\ . \ (14).$$

The constant parts in (14), viz. ½, may be determined by direct integration of (12), or from the observation that by their constitution G and H vanish when $u=\infty$, coupled with the fact that C and S then assume the value ½.

Comparing the expressions for C, S in terms of M, N, and in terms of G, H, we find that

$$G=\tfrac{1}{2}(\cos u+\sin u)-M,\quad H=\tfrac{1}{2}(\cos u-\sin u)+N\ . \quad (15),$$

formulæ which may be utilized for the calculation of G, H when u (or v) is small. For example when $u=0$, $M=0$, $N=0$, and consequently $G=H=\tfrac{1}{2}$.

Cauchy's series.

Descending series of the semi-convergent class, available for numerical calculation when u is moderately large, can be obtained from (12) by writing $x=uy$, and expanding the denominator in powers of y. The integration of the several terms may then be effected by the formula

$$\int_0^\infty e^{-y}y^{q-\frac{1}{2}}dy=\Gamma(q+\tfrac{1}{2})=(q-\tfrac{1}{2})(q-\tfrac{3}{2})\dots\tfrac{1}{2}\sqrt{\pi};$$

and we get in terms of v

$$G=\frac{1}{\pi^2v^3}-\frac{1.3.5}{\pi^4v^7}+\frac{1.3.5.7.9}{\pi^6v^{11}}- \quad . \quad . \quad . \quad (16),$$

$$H=\frac{1}{\pi v}-\frac{1.3}{\pi^3v^5}+\frac{1.3.5.7}{\pi^5v^9}- \quad . \quad . \quad . \quad . \quad . \quad (17)$$

The corresponding values of C and S were originally derived by Cauchy, without the use of Gilbert's integrals, by direct integration by parts.

From the series for G and H just obtained it is easy to verify that

$$\frac{dH}{dv}=-\pi vG,\quad\frac{dG}{dv}=\pi vH-1 \quad . \quad . \quad . \quad . \quad (18).$$

Straight edge.

We now proceed to consider more particularly the distribution of light upon a screen PBQ near the shadow of a straight edge A. At a point P within the geometrical shadow of the obstacle, the half of the wave to the right of C (Fig. 22), the nearest point on the wave-front, is wholly intercepted, and on the left the integration is to be taken from $s=$ CA to $s=\infty$. If V be the value of v corresponding to CA, viz.,

$$V=\sqrt{\left\{\frac{2(a+b)}{ab\lambda}\right\}}.CA, \quad . \quad . \quad . \quad . \quad . \quad . \quad (19),$$

we may write

$$I^2=\left(\int_V^\infty\cos\tfrac{1}{2}\pi v^2.dv\right)^2+\left(\int_V^\infty\sin\tfrac{1}{2}\pi v^2.dv\right)^2 \quad (20),$$

---

[1] In experiment a line of light is sometimes substituted for a point in order to increase the illumination. The various parts of the line are here *independent* sources, and should be treated accordingly. To assume a cylindrical form of primary wave would be justifiable only when there is synchronism among the secondary waves issuing from the various centres.

[2] *Mém. couronnés de l'Acad. de Bruxelles*, xxxi. 1. See also Verdet *Leçons*, § 86.

or, according to our previous notation,

$$I^2 = (\tfrac{1}{2} - Cv)^2 + (\tfrac{1}{2} - Sv)^2 = G^2 + H^2 \quad . \quad . \quad . \quad (21).$$

No bands inside shadow.

Now in the integrals represented by G and H every element diminishes as V increases from zero. Hence, as CA increases, viz., as the point P is more and more deeply immersed in the shadow, the illumination *continuously* decreases, and that without limit. It has long been known from observation that there are no bands on the interior side of the shadow of the edge.

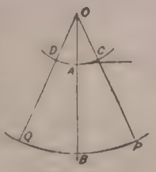

FIG. 22.

The law of diminution when V is moderately large is easily expressed with the aid of the series (16), (17) for G, H. We have ultimately $G = 0$, $H = (\pi V)^{-1}$, so that

$$I^2 = 1/\pi^2 V^2,$$

or the illumination is inversely as the square of the distance from the shadow of the edge.

For a point Q outside the shadow the integration extends over *more* than half the primary wave. The intensity may be expressed by

$$I^2 = (\tfrac{1}{2} + Cv)^2 + (\tfrac{1}{2} + Sv)^2 \quad . \quad . \quad . \quad . \quad (22);$$

and the maxima and minima occur when

$$(\tfrac{1}{2} + Cv)\frac{dC}{dV} + (\tfrac{1}{2} + Sv)\frac{dS}{dV} = 0,$$

whence

$$\sin \tfrac{1}{2}\pi V^2 + \cos \tfrac{1}{2}\pi V^2 = G \quad . \quad . \quad . \quad . \quad (23).$$

Position of exterior bands.

When $V = 0$, viz., at the edge of the shadow, $I^2 = \tfrac{1}{2}$; when $V = \infty$, $I^2 = 2$, on the scale adopted. The latter is the intensity due to the uninterrupted wave. The quadrupling of the intensity in passing outwards from the edge of the shadow is, however, accompanied by fluctuations giving rise to bright and dark bands. The position of these bands determined by (23) may be very simply expressed when V is large, for then sensibly $G = 0$, and

$$\tfrac{1}{2}\pi V^2 = \tfrac{3}{4}\pi + n\pi \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (24),$$

n being an integer. In terms of δ, we have from (2)

$$\delta = (\tfrac{3}{8} + \tfrac{1}{2}n)\lambda \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (25).$$

The first maximum in fact occurs when $\delta = \tfrac{3}{8}\lambda - .0046\lambda$, and the first minimum when $\delta = \tfrac{7}{8}\lambda - 0016\lambda$,[1] the corrections being readily obtainable from a table of G by substitution of the approximate value of V.

Hyperbolic propagation of bands.

The position of Q corresponding to a given value of V, that is to a band of given order, is by (19)

$$BQ = \frac{a+b}{a} AD = V\sqrt{\left\{\frac{b\lambda(a+b)}{2a}\right\}} \quad . \quad . \quad (26).$$

By means of this expression we may trace the locus of a band of given order as b varies. With sufficient approximation we may regard BQ and b as rectangular co-ordinates of Q. Denoting them by x, y, so that AB is axis of y and a perpendicular through A the axis of x, and rationalizing (26), we have

$$2ax^2 - V^2\lambda y^2 - V^2 a\lambda y = 0,$$

which represents a hyperbola with vertices at O and A.

From (24), (26) we see that the width of the bands is of the order $\sqrt{\{b\lambda(a+b)/a\}}$. From this we may infer the limitation upon the width of the source of light, in order that the bands may be properly formed. If ω be the apparent magnitude of the source seen from A, ωb should be much smaller than the above quantity, or

$$\omega < \sqrt{\{\lambda(a+b)/ab\}} \quad . \quad . \quad . \quad . \quad . \quad . \quad (27).$$

If a be very great in relation to b, the condition becomes

$$\omega < \sqrt{(\lambda/b)} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (28),$$

so that if b is to be moderately great (1 metre), the apparent magnitude of the sun must be greatly reduced before it can be used as a source.

	V	I^2
First maximum	1.2172	2.7413
First minimum	1.8726	1.5570
Second maximum	2.3449	2.3990
Second minimum	2.7392	1.6867
Third maximum	3.0820	2.3022
Third minimum	3.3913	1.7440

Fresnel's table.

The values of V for the maxima and minima of intensity, and the magnitudes of the latter, were calculated by Fresnel. An extract from his results is given in the preceding table.

A very thorough investigation of this and other related questions, accompanied by fully worked-out tables of the functions concerned, will be found in a recent paper by Lommel.[2]

Cornu's method.

When the functions C and S have once been calculated, the discussion of various diffraction problems is much facilitated by the idea, due to Cornu,[3] of exhibiting as a curve the relationship between C and S, considered as the rectangular co-ordinates (x, y) of a point. Such a curve is shown in Fig. 23, where according to the definition (5) of C, S,

$$x = \int_0^v \cos \tfrac{1}{2}\pi v^2 . dv, \quad y = \int_0^v \sin \tfrac{1}{2}\pi v^2 . dv \quad . \quad (29).$$

The origin of co-ordinates O corresponds to $v = 0$; and the asymptotic points J, J′, round which the curve revolves in an ever-closing spiral, corresponds to $v = \pm\infty$.

The intrinsic equation, expressing the relation between the arc σ (measured from O) and the inclination ϕ of the tangent at any point to the axis of x, assumes a very simple form. For

$$dx = \cos \tfrac{1}{2}\pi v^2 . dv, \quad dy = \sin \tfrac{1}{2}\pi v^2 . dv;$$

so that

$$\sigma = \int \sqrt{(dx^2 + dy)} = v, \quad . \quad . \quad . \quad . \quad (30),$$

$$\phi = \tan^{-1}\frac{dy}{dx} = \tfrac{1}{2}\pi v^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad (31).$$

Accordingly,

$$\phi = \tfrac{1}{2}\pi\sigma^2 \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (32);$$

and for the curvature,

$$\frac{d\phi}{d\sigma} = \pi\sigma \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (33).$$

Cornu remarks that this equation suffices to determine the general character of the curve. For the osculating circle at any point includes the whole of the curve which lies beyond; and the successive convolutions envelop one another without intersection.

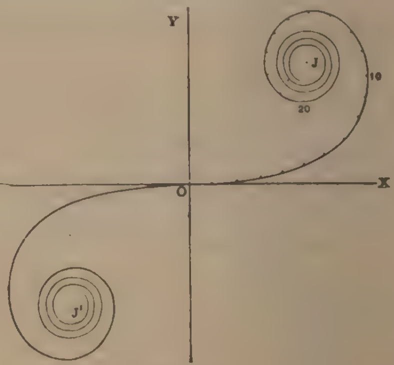

FIG. 23.

The utility of the curve depends upon the fact that the elements of arc represent, in amplitude and phase, the component vibrations due to the corresponding portions of the primary wave-front. For by (30) $d\sigma = dv$, and by (2) dv is proportional to ds. Moreover by (2) and (31) the retardation of phase of the elementary vibration from PQ (Fig. 21) is $2\pi\delta/\lambda$, or ϕ. Hence in accordance with the rule for compounding vector quantities, the resultant vibration at B, due to any finite part of the primary wave, is represented in amplitude and phase by the chord joining the extremities of the corresponding arc $(\sigma_2 - \sigma_1)$.

In applying the curve in special cases of diffraction to exhibit the effect at any point P (Fig. 22) the centre of the curve O is to be considered to correspond to that point C of the primary wave-front which lies nearest to P. The operative part, or parts, of the curve are of course those which represent the unobstructed portions of the primary wave.

Let us reconsider, following Cornu, the diffraction of a screen unlimited on one side, and on the other terminated by a straight edge. On the illuminated side, at a distance from the shadow, the vibration is represented by JJ′. The The co-ordinates of J, J′ being $(\frac{1}{2}, \frac{1}{2})$, $(-\frac{1}{2}, -\frac{1}{2})$, I^2 is 2; and the phase is $\frac{1}{8}$ period in arrear of that of the element at O. As the point under contemplation is supposed to approach the shadow, the vibration is represented by the chord drawn from J to a point on the other half of the curve, which travels inwards from J′ towards O. The amplitude is thus subject to fluctuations, which increase as the shadow is approached. At the point O the intensity is one-quarter of that of the entire wave, and after this point is passed, that is, when we have entered the geometrical shadow, the intensity falls off gradually to zero, *without fluctuations*. The whole progress of the phenomenon is thus exhibited to the eye in a very instructive manner.

Diffraction through a slit.

We will next suppose that the light is transmitted by a slit, and inquire what is the effect of varying the width of the slit upon the illumination at the projection of its centre. Under these circumstances the arc to be considered is bisected at O, and its length is proportional to the width of the slit. It is easy to see that the length of the chord (which passes in all cases through O) increases to a maximum near the place where the phase-retardation is $\frac{3}{8}$ of a period, then diminishes to a minimum when the retardation is about $\frac{7}{8}$ of a period, and so on.

If the slit is of constant width and we require the illumination at various points on the screen behind it, we must regard the arc of the curve as of *constant length*. The intensity is then as always, represented by the square of the length of the chord. If the slit be narrow, so that the arc is short, the intensity is constant over a wide range, and does not fall off to an important extent until the discrepancy of the extreme phases reaches about a quarter of a period.

Silvery lining of an obstacle.

We have hitherto supposed that the shadow of a diffracting obstacle is received upon a diffusing screen, or, which comes to nearly the same thing, is observed with an eye-piece. If the eye, provided if necessary with a perforated plate in order to reduce the aperture, be situated inside the shadow at a place where the illumination is still sensible, and be focused upon the diffracting edge, the light which it receives will appear to come from the neighborhood of the edge, and will present the effect of a silver lining. This is doubtless the explanation of a "pretty optical phenomenon, seen in Switzerland, when the sun rises from behind distant trees standing on the summit of a mountain."[1]

§ 18. *Diffraction Symmetrical about an Axis.*

The general problem of the diffraction pattern due to a source of light concentrated in a point, when the system is symmetrical about an axis, has been ably investigated by Lommel.[2] We must content ourselves here with a very slight sketch of some of his results.

Spherical waves, centred upon the axis, of radius a fall upon the diffracting screen; and the illumination is required on a second screen, like the first perpendicular to the axis, at a distance $(a+b)$ from the source. We have first to express the distance (d) between an element dS of the wave-front and a point M in the plane of the second screen. Let ζ denote the distance of M from the axis of symmetry; then, if we take an axis of x to pass through M, the co-ordinates of M are $(\zeta, 0, 0)$. On the same system the co-ordinates of dS are

$$a \sin\theta \cos\phi, \quad a \sin\theta \sin\phi. \quad a(1-\cos\theta)+b\,;$$

and the distance is given by

$$d^2 = b^2 + \zeta^2 - 2a\zeta \sin\theta \cos\phi + 4a(a+b)\sin^2\tfrac{1}{2}\theta.$$

In this expression ζ and θ are to be treated as small quantities. Writing ρ for $a \sin\theta$, we get approximately

$$d = b + \frac{\zeta^2}{2b} - \frac{\zeta\cos\phi}{b}\rho + \frac{a+b}{2ab}\rho^2 \quad . \quad . \quad . \quad (1).$$

The vibration at the wave-front of resolution being denoted by

$$a^{-1}\cos 2\pi t/\tau,$$

the integral expressive of the resultant of the secondary waves is (§ 17)

$$\frac{-1}{ab\lambda}\iint \sin 2\pi\left(\frac{t}{\tau} - \frac{d}{\lambda}\right)dS \quad . \quad . \quad . \quad . \quad (2).$$

Substituting $\rho d\rho\, d\phi$ for dS, and for d its value from (1), we obtain as the expression for the intensity at the point ζ,

$$I^2 = \frac{1}{a^2b^2\lambda^2}(C^2+S^2) \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (3),$$

where

$$C = \iint \cos\left(\tfrac{1}{2}\kappa\rho^2 - l\rho\cos\phi\right).\rho\, d\rho\, d\phi, \quad . \quad . \quad . \quad (4),$$

$$\text{[3]}S = \iint \sin\left(\tfrac{1}{2}\kappa\rho^2 - l\rho\cos\phi\right).\rho\, d\rho\, d\phi \quad . \quad . \quad . \quad (5),$$

and the following abbreviations have been introduced

$$\frac{2\pi}{\lambda}\,\frac{a+b}{2ab} = \tfrac{1}{2}\kappa, \quad \frac{2\pi\zeta}{\lambda b} = l \quad . \quad . \quad . \quad . \quad . \quad . \quad (6).$$

The range of integration is for ϕ from 0 to 2π. The limits for ρ depend upon the particular problem in hand: but for the sake of definiteness we will suppose that in the analytical definitions of C and S the limits are 0 and r, so as to apply immediately to the problem of a circular aperture of radius r. If we introduce the notation of Bessel's functions, we have

$$C = 2\pi\int_0^r J_0(l\rho)\cos(\tfrac{1}{2}\kappa\rho^2).\rho\, d\rho \quad . \quad . \quad . \quad . \quad . \quad (7).$$

$$S = 2\pi\int_0^r J_0(l\rho)\sin(\tfrac{1}{2}\kappa\rho^2).\rho\, d\rho \;.. \quad . \quad . \quad . \quad . \quad . \quad (8).$$

Lommel's series.

By integration by parts of these expressions Lommel develops series suitable for calculation. Setting

$$\kappa r^2 = y, \quad lr = z \quad . \quad . \quad . \quad (9),$$

he finds in the first place

$$C = \pi r^2\left\{\frac{\cos\frac{1}{2}y}{\frac{1}{2}y}U_1 + \frac{\sin\frac{1}{2}y}{\frac{1}{2}y}U_2\right\} . \quad . \quad . \quad . \quad (10),$$

$$S = \pi r^2\left\{\frac{\sin\frac{1}{2}y}{\frac{1}{2}y}U_1 - \frac{\cos\frac{1}{2}y}{\frac{1}{2}y}U_2\right\} . \quad . \quad . \quad . \quad (11),$$

where

$$U_1 = \frac{y}{z}J_1(z) - \frac{y^3}{z^3}J_3(z) + \frac{y^5}{z^5}J_5(z) - \quad . \quad . \quad . \quad . \quad (12),$$

$$U_2 = \frac{y^2}{z^2}J_2(z) - \frac{y^4}{z^4}J_4(z) + \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (13).$$

These series are convenient when y is less than z.

The second set of expressions are
